Nanomolar cholera toxin inhibitors based on symmetrical pentavalent ganglioside GM1os-sym-corannulenes†

Martin Mattarella,†a Jaime Garcia-Hartjes,†b Tom Wennekes,b Han Zuilhof*b,c and Jay S. Siegel*a

Eight symmetric and pentavalent corannulene derivatives were functionalized with galactose and the ganglioside GM1-oligosaccharide (GM1os) via copper-catalyzed alkyne-azide cycloaddition (CuAAC) reactions. The compounds were evaluated for their ability to inhibit the binding of the pentavalent cholera toxin to its natural ligand, ganglioside GM1. In this assay, all ganglioside GM1os-sym-corannulenes proved to be highly potent nanomolar inhibitors of cholera toxin.

One of the possible approaches for the design of CT inhibitors aims to prevent the receptor-recognition process. Two major routes can be discerned in the literature to achieve this goal. The first strategy, monovalent receptor-binding approach, focuses on strong binding interactions, and it is based on the design and synthesis of ligands that closely mimic the natural ligand on the cell surface in order to obtain a strong interaction with the CTB receptor. The second approach, multivalent receptor-binding, exploiting chelate cooperativity, takes advantage of the pentavalent character of the ligand-binding sites of CT. This approach is based on the synthesis of a functionalized branched system, in which each branch carries a single-site inhibitor, like galactose or lactose, leading to a compound that has an overall stronger interaction with the toxin than the sum of the independent inhibitors. The synthesis of dendritic multivalent inhibitors, functionalized with the GM1os, has been reported; these displayed unprecedented high inhibitory potencies for CTB, in the picomolar range.

An important improvement in the design of multivalent binders was achieved with symmetrical pentameric molecules based on the concept of “finger-linker-core” systems: the pentavalent “core” is connected by flexible “linkers” to “fingers” that include the monovalent receptor-binding ligand. Pentavalent CT inhibitors were synthesized using various “cores”: acylated pentacyclen, a large cyclic peptide and calix[5]arene.

This paper details a study that combines the two strategies to obtain an optimal binding by the design and synthesis of pentavalent GM1os-presenting compounds based on a 5-fold symmetrical sym-substituted corannulene scaffold (Fig. 1b). Binding assays allowed the determination of the interaction with CT-B5 (the protein complex without the toxic A part) for...
these and analogous pentavalent galactose corannulenes. This revealed a high inhibitory potency towards CTB by this new class of inhibitors.

2. Results and discussion

Apart from its obvious 5-fold symmetry, the corannulene scaffold is a good candidate to function as the “core” of pentavalent receptor-binding inhibitors for AB₅ toxins on the basis of the following observations: the recent development of a kilogram-scale synthesis of corannulene (1), its further functionalization to sym-pentachloro-corannulene (2), and the growing number of robust and flexible procedures for the preparation of molecular pentapods displaying functional groups and bioconjugated moieties, by iron-catalyzed cross-coupling and copper-catalyzed azide-alkyne cycloaddition (CuAAC) reaction.

The synthetic pathway towards PEG-corannulene systems starts from the conjugation of the terminal acetylene 3 by an efficient copper nanoparticle-catalyzed CuAAC reaction with n-mers of α-azidoethyl-ω-propargyl diglyme (n = 1, 2, 4) (Fig. S1 in the ESI†). This route gave satisfactory results for the preparation of other sym-bioconjugated corannulenes, and was used here to prepare the five-fold symmetric compounds 5, 6 and 7 in good yield and purity. The PEG arms function as linkers of different lengths and improve water solubility and flexibility of the inhibitor. The terminal TIPS-protected acetylenes were deprotected by reaction with TBAF yielding the alkyne-terminated PEG-corannulenes 8, 9 and 10 (Scheme 1).

After preparing the three PEG-corannulenes the focus shifted to attaching the (oligo)saccharides. In this work, two different CTB binders were used: galactose, an easily obtainable but quite poor binder of CTB, and the oligosaccharide of ganglioside GM1 (GM1os), the natural ligand of CTB.

In order to introduce the galactose-based “finger” to the terminal acetylenes 3, 8, 9 and 10, galactoside 11 was functionalized at the anomeric position with a short PEG chain that bears an azido group (compound 12, Scheme 2). An analogous compound without ethylene oxide moieties belonging to this inhibitor family was previously synthesized by CuAAC reaction on the terminal acetylene 3 and 2-azidoethyl-β-D-galactopyranoside. The synthetic pathway for the synthesis of azido-PEG-galactoside 14 starts with a Koenigs–Knorr-type glycosylation of azido-PEG hydroxide 12 with peracetylated galactosyl bromide 11 to afford β-galactoside 13. The deprotected compound 14 was then obtained by treatment of 13 with sodium methoxide. The pentavalent Gal-functionalized sym-corannulene inhibitor was prepared in good yield by employing the microwave-assisted CuAAC reaction on the
terminal acetylenes 3, 8, 9 and 10 with the azido galactose derivative 14 affording the four galactose-based CTB inhibitors 15–18 (Scheme 3).

The second family of pentavalent inhibitors displays five GM1os moieties (Scheme 4). The chemo-enzymatic synthesis from lactose of the azide-terminated GM1os oligosaccharide was previously reported. The pentavalent GM1os inhibitors 20, 21 and 22 were synthesized, in the presence of copper nanoparticles, by microwave-assisted CuAAC reaction of azido-pentasaccharide 19 with the terminal acetylenes 8, 9 and 10. Because of the low solubility of the GM1 analog in DMF, the reactions were performed in water, allowing a complete dissolution of 19 in the reaction media.

The inhibitory efficiency of the synthesized five-fold symmetric pentavalent CT ligands (15–18 and 20–22) was evaluated by an ELISA-type assay on 96-well plates. Solubility issues at concentrations >1 mM limited the experiments intended to find an IC50 value for galactose-based compounds.
When compared to previously reported IC$_{50}$ values for multivalent ligands functionalized with galactose,$^{10,11}$ these concentrations should not have been limiting. One hypothesis to account for this observation is that the supramolecular aggregation competes against binding to the pentad-complex.

Further investigations by $^1$H-NMR, UV-Vis and fluorescence spectroscopy on the properties of $C_5$-symmetric galactose conjugated corannulene in aqueous solution suggest the formation of supramolecular aggregates of this amphiphilic molecule in water. If the formation of the supramolecular

assemblies is thermodynamically and kinetically favored over the interaction with the CTB, the competition of these two processes might be a plausible explanation for the unexpected results obtained from the ELISA assays; however, the GM1os-PEG-corannulenes showed high, nanomolar inhibitory potencies (Fig. 2; Table 1).

The pentavalent GM1os-functionalized inhibitors, 20, 21, and 22, bind CTB at lower IC50 values than monomeric GM1os (cf. Table 1). The lowest IC50 value measured is for 21 (Table 1, entry 2) with an inhibition potency that is nearly 4000 times stronger than that of monomeric GM1os. The lower binding affinity for CTB by compounds 20 and 22 (Table 1, entries 1 and 3) is most probably due to the effects related to the linker length: if the linker is not long enough (compound 20), not all of the five ligands can simultaneously bind the five binding sites of CTB. In the opposite case (i.e. compound 22), binding would lead to a substantial ordering in the chain, making it entropically less favorable, while enthalpically the necessary folding of the longer linkers to enable binding of CTB by the GM1os fingers might create sufficient steric hindrance to cause an increased IC50 value. A further complicating factor is the possibility that galactose and GM1os derivatives undergo supramolecular self-aggregation that competes with binding to CTB and results in apparent higher inhibitory concentrations.

Caveats notwithstanding, 21 is as of yet one of the strongest multivalent CT inhibitors, and displays the power of combining the natural valency with the natural ganglioside to reach optimal blocking of multivalent lectins. Design efforts to create systems that optimize spacer geometry and avoid self-complexation will likely lead to new derivatives with inhibitory concentrations more favorably comparable to other previously reported GM1os-based inhibitors.

3. Conclusions

This manuscript reports a powerful method for the synthesis of a new class of cholera toxin inhibitors with a design based on a pentavalent sym-substituted corannulene as the core unit and equipped with the galactose and the GM1os as CTB binders. Microwave-assisted CuAAC reactions, catalyzed by copper nanoparticles, were employed for the conjugation of the monovalent CTB ligands (galactose and GM1os) to the corannulene core via azide-presenting PEG-linkers of various lengths. The potent CTB inhibition of 25, 5.0, and 7.3 nM observed for the penta-GM1os corannulenes, 20, 21, and 22, respectively, prove that multivalent systems functionalized with strong CTB binders represent a solid strategic approach for the synthesis of CT inhibitors with high potency in comparison with previously reported monovalent inhibitors.

The developed method allows for the use of sym-substituted corannulenes as a possible core unit for the development of new multivalent binders of cholera toxin or other possible biological targets that rely on multivalent binding of their target ligand.

4. Representative experimental procedures

Compound 6

A mixture of 3 (9.4 mg, 18 μmol), the proper azide-functionalized PEG (83.0 mg, 0.14 mmol) and copper nanoparticles (11.7 mg, 0.18 mmol) in DMF (1.0 mL) was loaded in a microwave vessel and was heated at 80 °C in a microwave reactor for 2 h. The reaction mixture was filtered over celite and the solvent evaporated. The crude mixture was purified by column chromatography on silica gel (from DCM–MeOH 9 : 1) to yield a reddish oil (49 mg, 79%).

$\text{H-NMR (500 MHz, CDCl}_3\text{): } \delta 7.69 (s, 5H), 7.64 (s, 5H), 7.53 (s, 5H), 4.62 (s, 1H), 4.48 (q, J = 5.5 Hz, 20 H), 4.21 (s, 10H), 3.82 (t, J = 5.0 Hz, 20 H), 3.69-3.47 (m, 90H), 3.26 (t, J = 8.0 Hz, 10H), 1.04 (s, 105H).

$\text{C-NMR (125 MHz, CDCl}_3\text{): } \delta 147.07, 144.81, 140.42, 134.88, 129.74, 123.91, 123.06, 122.47, 103.21, 87.81, 70.55, 70.54, 70.51, 70.47, 69.68, 69.64, 69.52, 68.72, 64.58, 59.28, 50.32, 50.27, 33.38, 28.49, 18.66, 11.20. HRMS (ESI) m/z: found 1163.6590 (M + 3Na); calc. (C_{175}H_{280}N_{30}Na_{3}O_{30}Si_{5}) 1163.6609.

Compound 9

A solution of TBAF in THF (1 M, 1.0 mL, 1.0 mmol) was added to a solution of 6 (103 mg, 30.1 μmol) in THF (1.0 mL) and the reaction mixture was stirred at r.t. for 2 h. The solution was then diluted with a saturated aqueous solution of NH₄Cl and...
extracted with ethyl acetate. The collected organic phases were dried over Na2SO4 and evaporated to yield the crude product. The crude was then heated at 75 °C under high vacuum for 18 h. The product was then purified by column chromatography on silica gel (DCM–MeOH 9:1) to yield a reddish oil (24 mg, 30%). 1H-NMR (500 MHz, CDCl3): δ 7.70 (s, 5H), 7.64 (s, 5H), 7.53 (s, 5H), 4.62 (s, 10H), 4.50–4.46 (m, 20H), 4.16 (d, J = 2.5 Hz, 10H), 3.82 (t, J = 5.0 Hz, 20H), 3.64–3.31 (m, 90H), 3.23 (t, J = 8.0 Hz, 10H), 2.44 (d, J = 2.5 Hz, 5H). 13C-NMR (125 MHz, CDCl3): δ 147.90, 144.84, 141.31, 134.78, 130.36, 126.25, 126.05, 124.76 70.57, 70.55, 70.47, 69.65, 69.52, 69.14, 64.72, 58.48, 50.26, 50.20, 33.39, 28.52. HRMS (ESI) m/z: found 529.2767 (M + 5H); calc. (C130H185N30O30) 529.2769.

Compound 17
A mixture of 9 (8.5 mg, 3.2 μmol) and copper nanoparticles (1.5 mg, 23.6 μmol) in DMF (300 μL) was loaded into a microwave vessel and was heated at 80 °C in a microwave reactor for 2 h. The mixture was filtrated over celite and the solid was washed with water. The crude was lyophilized and purified by size exclusion chromatography (Sephadex® G-25) to yield a reddish solid (9.1 mg, 57%).

1H-NMR (500 MHz, CDCl3): δ 8.01 (s, 5H), 7.88 (s, 5H), 7.68 (s, 5H), 7.60 (s, 5H), 4.58–4.39 (m, 50H), 4.08–4.06 (m, 5H), 3.98–3.12 (m, 255H). 13C-NMR (125 MHz, D2O/d4-MeOD): δ 147.90, 144.84, 141.31, 134.78, 130.36, 126.25, 126.05, 124.76 70.57, 70.55, 70.47, 69.65, 69.52, 69.14, 64.72, 58.48, 50.26, 50.20, 33.39, 28.52. HRMS (ESI) m/z: found 529.2767 (M + 5H); calc. (C130H185N30O30) 529.2769.

Compound 21
A mixture of 9 (2.88 mg, 1.09 μmol) and copper nanoparticles (0.76 μmol, 12 μmol) in water (300 μL) was loaded into a microwave vessel and was heated at 80 °C in a microwave reactor for 2 h. The mixture was filtrated over celite and the solid was washed with water. The crude was lyophilized and purified by size exclusion chromatography (Sephadex® G-25, water) to yield a reddish solid (9.1 mg, 57%). 1H-NMR (500 MHz, D2O/d4-MeOD): δ 7.70 (s, 5H), 7.64 (s, 5H), 7.53 (s, 5H), 4.62 (s, 10H), 4.50–4.46 (m, 20H), 4.16 (d, J = 2.5 Hz, 10H), 3.82 (t, J = 5.0 Hz, 20H), 3.64–3.31 (m, 90H), 3.23 (t, J = 8.0 Hz, 10H), 2.44 (d, J = 2.5 Hz, 5H). 13C-NMR (125 MHz, CDCl3): δ 147.11, 144.83, 140.47, 134.89, 129.76, 123.97, 123.07, 122.47, 79.70, 74.86, 70.57, 70.55, 70.47, 69.65, 69.52, 69.14, 64.72, 58.48, 50.26, 50.20, 33.39, 28.52. HRMS (ESI) m/z: found 529.2767 (M + 5H); calc. (C130H185N30O30) 529.2769.

Notes and references
Prefix sym is used here to indicate the C5-symmetric substituted corannulene corresponding to 1,3,5,7,9-pentasubstitution.
