We report the preparation of four new double-bridged PNP-lariat ether derivatives **L1–L4** synthesized from precursor **1** by the subsequent substitution of chlorine atoms. The process consists of two steps. In the first one two reactive chlorine atoms of the  $-PCl_2$  exocyclic moiety are substituted with respective nucleophiles: 2,2'-thiodiethanethiol **2** and 2,2'-oxydiethanethiol **3**. In the second step the other chlorine atoms are substituted by aziridynyl **6** and pyrrolidinyl **7** groups, respectively. Their structures were established by MS,  $^1H$  NMR,  $^{31}P$  NMR,  $^{13}C$  NMR spectroscopy. Furthermore, this work includes the investigation of complexation of silver(i) ions with the new ligands **L1–L4** in methanol solution. The formation of the novel tetra-nuclear silver(i) complexes were observed. Stability constants were determined using a simple potentiometric titration.  $^1H$  NMR,  $^{31}P$  NMR,  $^{13}C$  NMR spectra were recorded to investigate how the complexation of silver(i) ions by the investigated macrocyclic ligands occurs.

### Introduction

Lariat ethers are group of compounds still considered to be attractive research objects.<sup>1–4</sup> The term “lariat ether” refers to a crown ether having a side chain attached to the crown moiety by the so-called pivot atoms (C, N or P). The side arms contain atoms or groups with a lone pair of electrons that can cooperate with the electrons of the macrocycle ring heteroatoms, thus providing a three-dimensional coordination of the guest cation.<sup>5–7</sup> We know three types of lariat ethers depending on the atom to which side arm is attached. When the bonding of side arm is realised through carbon we obtain C-pivot lariat ethers,<sup>8,9</sup> nitrogen – N-pivot lariat ethers<sup>10,11</sup> and through phosphorus atom – P-pivot lariat ethers.<sup>12,13</sup>

The subjects of this publication are the P-pivot lariat ether derivatives. This is the class of reactive crown ethers which was formed by cyclocondensation of hexachlorocyclotriphosphazene with tetraethylene glycol in the presence of sodium hydride.<sup>14,15</sup> The closure of the ring was assisted by the sodium cation which served as a template.<sup>16,17</sup> The interaction with five oxygen donors of the polyether substrate which wrapped itself around the alkali metal cation satisfies its coordination requirements, thereby favouring ring closure to form the macrocycle.<sup>18</sup> This type of lariat ethers may be regarded as “intelligent substrate” because it possesses reactive sites capable for spontaneous self assembling with molecular complementary reagents. This compound has the reactive chloride substituents, capable of undergoing various

substitution reaction, in particular with sodium arylates<sup>19–21</sup> and different amines.<sup>22–24</sup>

Due to the presence of binding sites in the form of both oxygen and nitrogen donor atoms, these ligands form stable complexes with cations of alkali metals and alkaline earth metals as well as transition metals.<sup>25–27</sup>

PNP-lariat ethers and their complexes are proved antitumor activity<sup>28</sup> and anti-AIDS activity.<sup>29</sup> This antiproliferative activity may be modified by the formation of complexes with metal ions. The thio-substituted macrocyclic derivatives of cyclo-triphosphazenes are commonly used for removing highly toxic, heavy metals pollutants and for recovering of some valuable metal ions (*e.g.* silver) from the industrial wastes.<sup>30</sup>

Complexing abilities of these compounds give the possibility for modelling of biological systems, in which sulfur-organic compounds are involved.<sup>31</sup> Reaction of the PNP-lariat ethers with diamines represents interesting type of supramolecular control. We observe the regioselective involvement of the chlorine atoms adjacent to macrocyclic skeleton into the interactions with diamines, while chlorine situated in more distant positions from macrocyclic ring are neglected.<sup>32–34</sup> They form transannular cyclophosphazene derivatives rather than the thermodynamically most favourable spiro-cyclosubstituted products, which are usually formed in the reaction of chlorocyclophosphazenes with short-chain diamines.<sup>35–38</sup> In this type of reaction in general we always obtain the mixture of three types of structures, namely: intramolecular ansa diamino-bridged PNP-cryptands, as well as mono (bino) and doubly-bridged, bis-PNP-crown (bis-bino) derivatives, in which diamines span the positions adjacent to the macrocycles (Scheme 1).<sup>39</sup>

**Scheme 1** Polymacrocyclic structures formed in the reaction of chlorocyclophosphazenes with diamines.

Depending on the reaction conditions, in particular the molar ratio of the reagents, their concentration in reaction mixture, as well as the reaction temperature and the nature of the solvent – all three polymacrocyclic structures are formed, as was mentioned above, but the yields of the separated reaction products are different.

In this work we present the most efficient synthetic conditions leading to obtain four doubly-bridged PNP-lariat ethers and describe their complexes with silver(I) ions in methanol solution. All these macrocyclic derivatives of cyclotriphosphazene were synthesized in two subsequent steps (Scheme 2). For bridging two molecules of tetrachloro-PNP-lariat ethers **1** we used 2,2'-thiodiethanethiol **2** and 2,2'-oxydiethanethiol **3**. In the first step of the reaction we obtained the spiro derivatives **4** and **5** unlike in the case of the reactions of the investigated derivatives with diamines.<sup>32</sup> Then, in the second reaction step endocyclic phosphorus atoms were substituted with aziridine **6** and pyrrolidine **7** groups. In such a way we obtained derivatives **L1**, **L2**, **L3** and **L4**.

All ligands have several structural units which can potentially take part in binding of metal cations: the polyether oxygen donors of the macrocyclic PNP-crown skeleton, the endocyclic nitrogen atom of cyclophosphazene ring, the nitrogen atoms of

the aziridynyl or pyrrolidynyl substituents, and the sulfur or oxygen donor atoms of the two bridging chains.

In this publication doubly-bridged derivatives of compound **1** have been synthesized and describe by NMR spectra as well as MS and DCS measurements.

Furthermore, this work covers the comparison of stability constants of complexes with silver(I) ions in methanol solutions.

## Experimental sections

### Materials

Sodium hydride, 60% dispersion in mineral oil, 2,2'-thiodiethanethiol (90%) and 2,2'-oxydiethanethiol (95%) from Aldrich were used as received. Aziridine (99%) from Fluka AG and pyrrolidine (99%) from Aldrich were distilled over KOH pellets under argon atmosphere before use.

THF (POCH Gliwice) was distilled over cuprous chloride, then over calcium hydride, and finally twice over sodium-potassium alloy under an argon atmosphere, *n*-hexane (Merck) was used without purification. Methanol (POCH Gliwice) (99.8%) was used as received. For column chromatography silica gel 60 (100–200 mesh Merck) was used. The reactions were carried under a dry argon atmosphere.

**Scheme 2** Syntheses of doubly-bridged PNP-lariat ethers.

## Methods

TLC analyses were performed on Merck precoated silica gel 60 plates. Flash chromatography was carried out with silica gel (100–200 mesh Merck), with hexane–THF mixture as eluent. Electrospray mass spectrometric analyses (ESI-MS) were recorded on a Finnigan LCQ ion trap spectrometer (Finnigan, San Jose, CA, USA). The sample was dissolved in methanol and the solution was introduced into the ESI-MS source by continuous infusion by means of the instrument syringe pump at a rate of  $3 \mu\text{l min}^{-1}$ . The ESI-source was operated at 4.25 kV and the capillary heater was set to  $200^\circ\text{C}$ . For fragmentation experiments, mass selected monoisotopic molecular ions were isolated in the ion trap and collisionally activated with 32% ejection RF-amplitude at standard He pressure. The experiments were performed in positive ion-mode.

Differential scanning calorimetry (DSC) measurements were done using a DuPont 1090B apparatus with a heating rate of  $20^\circ\text{C min}^{-1}$  under the nitrogen atmosphere.

In order to define the structure of compound **L1–L4**  $^1\text{H}$  NMR spectra were recorded on a Bruker Avance III 600 spectrometer using solutions in  $\text{CDCl}_3$ .  $^{31}\text{P}$  NMR spectra were recorded on the same spectrometer operating at 242 MHz using solutions in  $\text{CDCl}_3$ , and 85%  $\text{H}_3\text{PO}_4$  as an external reference, with positive shifts recorded downfield from reference. In most cases both proton-coupled and proton-decoupled  $^{31}\text{P}$  NMR spectra were obtained. For  $^{13}\text{C}$  NMR measurements only proton-decoupled 151 MHz spectra were recorded.

Additionally,  $^1\text{H}$  NMR,  $^{31}\text{P}$  NMR,  $^{13}\text{C}$  NMR, HMBC and HMQC spectra of complexes were taken in order to study how

the cation complexation of silver(I) ions by the investigated macrocyclic ligands occurs. All spectra in this part of work were recorded on a Bruker Avance III 600 spectrometer using solutions in  $\text{CD}_3\text{OD}$ .

The potentiometric measurements were carried out with the use of Cerko microburette controlled by computer with silver electrode  $\text{Ag}^0/0.01 \text{ M AgNO}_3 + 0.1 \text{ M (C}_2\text{H}_5)_4\text{NNO}_3$  in methanol solution as reference electrode. The activity of the uncomplexed silver ions was calculated from the emf values using the Nernst equation verified at the first step of the measurement procedure.<sup>27</sup> The stability constants were calculated using HYPERQUAD 2003 program.<sup>40</sup>

## Synthesis

The synthesis of all compound required two steps (1 and 2).

**L1** – 1,1',3,3' – bis(oxytetraethyleneoxy) – 5,5,5',5' – bis(2,2'-thiodiethanethiol) – 1,1',3,3' – tetra(aziridinylo)cyclotriphosphazatriene.

Step 1. 0.469 g (1 mmol) of 1,3-(oxytetraethyleneoxy)-1,3,5-tetrachlorocyclotriphosphazene **1**, 0.3429 g (2 mmol) 2,2'-thiodiethanethiol **2** and 0.08 g (2 mmol) of 60% sodium hydride were dissolved in 20 ml of THF and placed in a 100 ml, 3-necked round-bottomed flask equipped with a mechanical stirrer and argon inlet. The reaction mixture was stirred under argon for 2 h in an ice bath then an ice bath was removed and synthesis was carried out at room temperature for 24 hours. The progress of the reaction was traced on TLC plates in hexane : THF = 1 : 5 as eluent.

Step 2. The solution of the obtained in the first step intermediate product **4** and 0.344 g (8 mmol) of aziridine **6** and **8**

pellets NaOH were dissolved in 20 ml hexane. The synthesis was carried out under argon at room temperature for 23 hours. The resulting mixture was filtered, the solvents were evaporated from the filtrate and crude product was isolated by flash chromatography on silica gel using hexane : THF = 1 : 2 as eluent. The yield of the obtained product was 21%.

$^{31}\text{P}$  NMR spin system  $A_2B$  (242 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{p}}$  [ppm], 25.2 (d,  $\text{P}(\text{OCH}_2)\text{Az}$ ), 54.2 (t,  $\text{P}(\text{SCH}_2)_2$ ),  $J_{\text{PP}} = 18.0$  [Hz];  $^1\text{H}$  NMR (600 MHz  $\text{CDCl}_3$ )  $\delta_{\text{H}}$  [ppm]: 4.18 (m, 8H,  $\text{CH}_2\text{OP}$ ), 3.72 (m, 24H,  $\text{CH}_2\text{OC}$ ), 3.07 (m, 16H,  $\text{CH}_2\text{S}$ ), 2.07 (m, 16H,  $\text{CH}_2\text{N}$ );  $^{13}\text{C}$  NMR (151 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{c}}$  [ppm]: 71.0, 70.9 (d,  $^2J_{\text{PC}} = 3.1$  Hz), 70.1 (d,  $^3J_{\text{PC}} = 1.4$  Hz), 65.1 (d,  $^2J_{\text{PC}} = 2.3$  Hz), 38.7 (d,  $^3J_{\text{PC}} = 1.1$  Hz), 32.7 (d,  $^2J_{\text{PC}} = 1.9$  Hz), 32.4 (d,  $^2J_{\text{PC}} = 2.9$  Hz), 24.2 (d,  $^2J_{\text{PC}} = 1.6$  Hz); mp = 106.8 °C, differential scanning calorimetry (DSC); ESI-MS  $m/z = 1127.3$  ( $\text{M} + \text{H}^+$ ), 1151.2 ( $\text{M} + \text{Na}^+$ ).

**L2** – 1,1',3,3' – bis(oxytetraethyleneoxy) – 5,5,5',5' – bis(2,2'-thiodiethanethiol) – 1,1',3,3' – tetra(pyrrolidinylo)cyclotriphosphazatriene.

Step 1. 0.469 g (1 mmol) of 1,3-(oxytetraethyleneoxy)-1,3,5,5-tetrachlorocyclotriphosphazene **1**, 0.3429 g (2 mmol) 2,2'-thiodiethanethiol **2** and 0.08 g (2 mmol) of 60% sodium hydride were dissolved in 20 ml of THF and placed in a 100 ml, 3-necked round-bottomed flask equipped with a mechanical stirrer and argon inlet. The reaction mixture was stirred under argon for 2 h in an ice bath then an ice bath was removed and synthesis was carried out at room temperature for 24 hours. The progress of the reaction was traced on TLC plates in hexane : THF = 1 : 1 as eluent.

Step 2. The solution of the obtained in the first step intermediate product **4** and 0.5747 g (8 mmol) of pyrrolidine **7** were dissolved in 20 ml hexane. The synthesis was carried out at room temperature for 21 hours. The resulting mixture was filtered, the solvents were evaporated from the filtrate and product was isolated by flash chromatography on silica gel using hexane : THF = 3 : 1, then 2 : 1, 1 : 1, THF and finally methanol as eluent. The yield of the obtained product was 34%.

$^{31}\text{P}$  NMR spin system  $A_2B$  (242 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{p}}$  [ppm], 16.8 (d,  $\text{P}(\text{OCH}_2)\text{Pir}$ ), 52.0 (t,  $\text{P}(\text{SCH}_2)_2$ ),  $J_{\text{PP}} = 19.2$  [Hz];  $^1\text{H}$  NMR (600 MHz  $\text{CDCl}_3$ )  $\delta_{\text{H}}$  [ppm]: 4.06 (m, 8H,  $\text{CH}_2\text{OP}$ ), 3.70 (m, 24H,  $\text{CH}_2\text{OC}$ ), 3.15 (m, 16H,  $\text{CH}_2\text{N}$ ), 3.00 (m, 16H,  $\text{CH}_2\text{S}$ ), 1.82 (m, 16H,  $\text{CH}_2\text{C}$ );  $^{13}\text{C}$  NMR (151 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{c}}$  [ppm]: 71.0, 70.8 (d,  $^2J_{\text{PC}} = 3.2$  Hz), 70.1 (d,  $^3J_{\text{PC}} = 1.1$  Hz), 64.3 (d,  $^2J_{\text{PC}} = 2.2$  Hz), 46.6 (d,  $^2J_{\text{PC}} = 2.1$  Hz) 38.7 (d,  $^3J_{\text{PC}} = 1.2$  Hz), 32.6 (d,  $^2J_{\text{PC}} = 2.4$  Hz), 31.6 (d,  $^2J_{\text{PC}} = 2.3$  Hz), 26.5 (d,  $^3J_{\text{PC}} = 2.1$  Hz); mp = 114.2 °C, differential scanning calorimetry (DSC); ESI-MS  $m/z = 1239.6$  ( $\text{M} + \text{H}^+$ ), 1261.6 ( $\text{M} + \text{Na}^+$ ).

**L3** – 1,1',3,3' – bis(oxytetraethyleneoxy) – 5,5,5',5' – bis(2,2'-oxydiethanethiol) – 1,1',3,3' – tetra(aziridinylo)cyclotriphosphazatriene.

Step 1. 0.469 g (1 mmol) of 1,3-(oxytetraethyleneoxy)-1,3,5,5-tetrachlorocyclotriphosphazene **1**, 0.3072 g (2 mmol) 2,2'-oxydiethanethiol **3** and 0.08 g (2 mmol) of 60% sodium hydride were dissolved in 20 ml of THF and placed in 100 ml 3-necked round-bottomed flask equipped with a mechanical stirrer and argon inlet. The reaction mixture was stirred under argon for 2 h in an ice bath then an ice bath was removed and synthesis was carried out at room temperature for 24 hours. The

progress of the reaction was traced on TLC plates with hexane : THF = 1 : 5 as eluent.

Step 2. The solution of the obtained in the first step intermediate product **5** and 0.344 g (8 mmol) of aziridine **6** and 8 pellets of NaOH were dissolved in 20 ml hexane. The synthesis was carried out at room temperature for 23 hours. The resulting mixture was filtered, the solvents were evaporated from the filtrate and product was isolated by flash chromatography on silica gel using hexane : THF = 1 : 1, then 2 : 3, 1 : 2, 1 : 3, THF and finally methanol as eluent. The yield of the obtained product was 25%.

$^{31}\text{P}$  NMR spin system  $A_2B$  (242 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{p}}$  [ppm], 25.4 (d,  $\text{P}(\text{OCH}_2)\text{Az}$ ), 55.2 (t,  $\text{P}(\text{SCH}_2)_2$ ),  $J_{\text{PP}} = 14.1$  [Hz];  $^1\text{H}$  NMR (600 MHz  $\text{CDCl}_3$ )  $\delta_{\text{H}}$  [ppm]: 4.17 (m, 8H,  $\text{CH}_2\text{OP}$ ), 3.77 (m, 8H,  $\text{CH}_2\text{OCH}_2\text{CH}_2\text{S}$ ), 3.70 (m, 24H,  $\text{CH}_2\text{OC}$ ), 3.09 (m, 8H,  $\text{CH}_2\text{S}$ ), 2.06 (m, 16H,  $\text{CH}_2\text{N}$ );  $^{13}\text{C}$  NMR (151 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{c}}$  [ppm]: 71.1, 70.8 (d,  $^2J_{\text{PC}} = 3.3$  Hz), 70.1 (d,  $^3J_{\text{PC}} = 2.2$  Hz), 69.1 (d,  $^3J_{\text{PC}} = 3.6$  Hz), 65.0 (d,  $^2J_{\text{PC}} = 2.4$  Hz), 31.9 (d,  $^2J_{\text{PC}} = 1.3$  Hz), 21.1 (d,  $^2J_{\text{PC}} = 1.2$  Hz); mp = 77.0 °C, differential scanning calorimetry (DSC); ESI-MS  $m/z = 1095.1$  ( $\text{M} + \text{H}^+$ ), 1117.3 ( $\text{M} + \text{Na}^+$ ).

**L4** – 1,1',3,3' – bis(oxytetraethyleneoxy) – 5,5,5',5' – bis(2,2'-oxydiethanethiol) – 1,1',3,3' – tetra(pyrrolidinylo)cyclotriphosphazatriene.

Step 1. 0.469 g (1 mmol) of 1,3-(oxytetraethyleneoxy)-1,3,5,5-tetrachlorocyclotriphosphazene **1**, 0.3072 g (2 mmol) 2,2'-oxydiethanethiol **3** and 0.08 g (2 mmol) of 60% sodium hydride were dissolved in 20 ml of THF and placed in 100 ml 3-necked round-bottomed flask equipped with a mechanical stirrer and argon inlet. The reaction mixture was stirred under argon for 2 h in an ice bath then an ice bath was removed and synthesis was carried out at room temperature for 24 hours. The progress of the reaction was traced on TLC plates with hexane : THF = 1 : 1 as eluent.

Step 2. The solution of the obtained in the first step intermediate **5** product and 0.5747 g (8 mmol) of pyrrolidine **7** were dissolved in 20 ml hexane. The synthesis was carried out at room temperature for 21 hours. The resulting mixture was filtered, the solvents were evaporated from the filtrate and product was isolated by flash chromatography on silica gel using hexane : THF = 3 : 1, then 2 : 1, 1 : 1, THF and finally methanol as eluent. The yield of the obtained product was 40%.

$^{31}\text{P}$  NMR spin system  $A_2B$  (242 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{p}}$  [ppm], 17.1 (d,  $\text{P}(\text{OCH}_2)\text{Pir}$ ), 52.9 (t,  $\text{P}(\text{SCH}_2)_2$ ),  $J_{\text{PP}} = 14.8$  [Hz];  $^1\text{H}$  NMR (600 MHz  $\text{CDCl}_3$ )  $\delta_{\text{H}}$  [ppm]: 4.09 (m, 8H,  $\text{CH}_2\text{OP}$ ), 3.78 (m, 8H,  $\text{CH}_2\text{OCH}_2\text{CH}_2\text{S}$ ), 3.68 (m, 24H,  $\text{CH}_2\text{OC}$ ), 3.17 (m, 16H,  $\text{CH}_2\text{N}$ ), 3.10 (m, 8H,  $\text{CH}_2\text{S}$ ), 1.81 (m, 16H,  $\text{CH}_2\text{C}$ );  $^{13}\text{C}$  NMR (151 MHz,  $\text{CDCl}_3$ )  $\delta_{\text{c}}$  [ppm]: 71.0, 70.9 (d,  $^2J_{\text{PC}} = 3.2$  Hz), 70.2 (d,  $^3J_{\text{PC}} = 1.1$  Hz), 69.3 (d,  $^3J_{\text{PC}} = 3.1$  Hz), 64.3 (d,  $^2J_{\text{PC}} = 2.2$  Hz), 46.6 (d,  $^2J_{\text{PC}} = 2.7$  Hz), 31.9 (d,  $^2J_{\text{PC}} = 2.3$  Hz), 26.4 (d,  $^3J_{\text{PC}} = 2.1$  Hz); mp = 83.2 °C, differential scanning calorimetry (DSC); ESI-MS  $m/z = 1207.4$  ( $\text{M} + \text{H}^+$ ), 1229.5 ( $\text{M} + \text{Na}^+$ ).

## Results and discussion

The investigated ligands form several complex products with silver(i) ions. The obtained stepwise stability constants were collected in Table 1. Additionally the results of two previously

described derivatives (with only one macrocyclic chain) presented on Fig. 1 were attached in order to compare the obtained values.

In case of aziridine substituted derivative (L5), two forms of complexes were observed  $\text{AgL}$  (1 : 1) and  $\text{AgL}_2$  (1 : 2) and the preferred is 1 : 1 adduct. Such behaviour is probably connected with lowering of the electrodonor properties of the endocyclic cyclotriphosphazene N atom, arose from the presence of aziridine substituents. The weaker N– $\text{Ag}^+$  interaction gives the possibility of stronger binding of the cation by oxygen donor atoms from crown ether moiety of the ligand. The silver ion is strongly accommodated inside the ligand cavity what makes the formation of sandwich type complex  $\text{AgL}_2$  more difficult. Hence the lower stability constant of this system is observed.

The formation of  $\text{Ag}_2\text{L}$  do not occurred due to the deficiency of the binding places in the macrocyclic ring, what was confirmed by the potentiometric measurement results. The second  $\text{Ag}^+$  ion is usually bound to the oxygen atoms from the ether moiety of the ring. Such situation was observed in case of the derivative with pyrrolidinyl substituents (L6). Aziridinyl substituents substantially decrease the stability of the obtained complexes in comparison with the pyrrolidinyl ones. For L6 complexes the stepwise stability constants are  $\log \beta = 4.38$  ( $\text{AgL}$ ) and  $\log \beta = 3.14$  for  $\text{AgL}$  and  $\text{AgL}_2$  respectively, and for L5 ligand  $\log \beta = 3.33$  and  $\log \beta = 2.62$  for  $\text{AgL}$  and  $\text{AgL}_2$  respectively. Furthermore for L6 derivatives one more stability constant is observed for  $\text{Ag}_2\text{L}$  complexed form which is equal  $\log \beta = 2.67$ .

Such behaviour is possible due to shorter N– $\text{Ag}^+$  binding and therefore availability of oxygen atoms from macrocyclic ether ring. Comparing the stability constant of 15C5 crown ether in methanol solutions presented in the literature (3.07),<sup>43</sup> we noticed that in the case of the tetrapyrrolidinyl as well as tetraaziridinyl derivatives, the obtained complexes are much more stable. Furthermore in the cited paper there were no other forms of complexes observed, which suggests that in the case of the simple crown ether the silver cation is nested inside the cavity which makes the formation of other types of complexes impossible. The complexes with mono aza 15C5 crown derivative due to the presence of a nitrogen atom in the ligand molecule show much stronger coordination of silver ions 5.52 in methanol.<sup>44</sup> Furthermore the presence of sandwich complexes was also observed.

In case of investigated ligands L1–L4 their common characteristic is that their structure consist of three macrocyclic systems. Two of them are formed from the crown ether moieties attached to the cyclotriphosphazene ring and the third one is

Fig. 1 Aziridine substituted PNP – lariat ether (L5)<sup>24</sup> and pyrrolidine substituted PNP – lariat ether (L6).<sup>24,26</sup>

formed by two bridges connecting two PNP-lariat ether systems. In case of L1 and L2 ligands, the additional macrocyclic ring formed through two 2,2'-thiodiethanethiol moieties, gives six sulfur atoms able to bind silver(i) ions. The bridges of the ligands L3 and L4 formed through two 2,2'-oxydiethanethiol moieties, possess four sulfur and two oxygen atoms theoretically able to bind metal ions.

Replacing of oxygen donor atoms in crown ethers with soft sulfur or nitrogen donor atoms causes the increase in stability constants of the obtained silver ion complexes.<sup>41,42</sup> The main reason for such effect is connected with more covalent character of the S– $\text{Ag}^+$  and N– $\text{Ag}^+$  bonding. Such increase in stability constants is observed within the L1–L4 compounds.

In the case of  $\text{AgL}$  system the much higher values of stability constants suggest that the stabilization of the system is realized through six or four sulfur atoms (for L1, L2 or L3, L4 ligand respectively) from the macrocyclic moiety situated in the centre of the investigated molecules. Stability constants values for complexes with L1 and L2 ligands are much higher than for complexes with L3 and L4 ligands. This fact is probably connected with the replacing of two oxygen atoms with two sulfur atoms in the bridge fragments of the investigated compounds.

### NMR measurements

In order to determine the way of silver(i) ions complexation by investigated ligands, the NMR spectra in methanol of the L1 and L4 compounds were done as well as the spectra of their complexes – after adding of silver ions with the amounts corresponding to suitable molar  $\text{Ag} : \text{L}$  ratio. All data were collected in Table 2 and Table 3 for ligand L1 and L4 respectively.

Table 1 The values of stepwise stability constants of investigated complexes in methanol solution

| Complex form  | L1 $\log \beta$ | L2 $\log \beta$ | L3 $\log \beta$   | L4 $\log \beta$   | L5 $\log \beta$ | L6 <sup>a</sup> $\log \beta$ |
|---|-----------------|-----------------|-------------------|-------------------|-----------------|------------------------------|

For better visualization of the obtained results  $^1\text{H}$  NMR spectra were presented on Fig 2 and Fig. 3 for ligand **L1** and **L4** respectively.

On the basis of  $^1\text{H}$  NMR analysis for ligand **L1** and its complexes, after adding of the first silver ion portion (Ag : L = 0.5 : 1) the significant shift (0.07 ppm) of the signal within the CH<sub>2</sub>S group originated from the 2,2'-thiodiethanethiol bridges was observed. This can support the fact that silver ion is strongly bound by sulfur atoms of the third macrocyclic ring placed in the center of the molecule.  $^{31}\text{P}$  NMR measurements show that in this case probably two such system exist – forming sandwich complexes Fig. 4a with slight shift between two ligand

molecules Fig. 5 (two triplets at 53.6 ppm and 53.4 ppm and two doublets at 25.3 and 25.2 ppm).

$^{31}\text{P}$  NMR for the AgL system show that the structure of this form of complex is relatively stiff – only one triplet at 53.3 ppm from exocyclic phosphorous atoms as well as one doublet at 25.4 ppm from the endocyclic phosphorous atom is seen on the spectrum. Furthermore on  $^1\text{H}$  NMR spectrum further shift (of about 0.07 ppm) within the CH<sub>2</sub>S protons region is observed – what can be explained by the deeper allocation of silver ion within the ligand cavity (Fig. 4b).

In case of Ag<sub>2</sub>L system there is further downfield shift of CH<sub>2</sub>S group protons what suggests the addition of the second

**Fig. 2**  $^1\text{H}$  NMR spectra in methanol for uncomplexed ligand **L1** – (a) and after adding silver ion with the Ag : L molar ratio 0.5 : 1, 1 : 1, 2 : 1, 3 : 1 and 4 : 1 – spectrum b, c, d, e, and f respectively.

**Fig. 3**  $^1\text{H}$  NMR spectra in methanol for uncomplexed ligand **L4** (a) and after adding silver ion with the Ag : L molar ratio 0.5 : 1, 1 : 1, 2 : 1, 3 : 1 and 4 : 1 – spectrum b, c, d, e, and f respectively.

silver ion is realized through the same part of the centered macrocyclic ring (Fig. 4c). This hypothesis is confirmed by  $^1\text{H}$ - $^{31}\text{P}$  NMR spectrum on which the multiplet assigned to phosphorous from the bridging part of the ligand is slightly splitted into two parts (multiplet 3.38 ppm and 52.2 ppm) (Fig. 6). This splitting is probably caused by unequal location of two silver ions toward donor sulfur atoms from the bridging moieties of the ligand.

In case of triple excess of silver ions over the ligand –  $\text{Ag}_3\text{L}$ , quite significant separation of the signals originated from the  $\text{CH}_2\text{OP}$  group is observed. This fact is probably connected with the binding of additional silver ion by endocyclic nitrogen atom from one of the terminal macrocyclic part of the ligand (Fig. 4d). Such effect was observed in cases of monomacrocyclic PNP-lariat ethers.<sup>27</sup> After adding next portion of silver ion to the ligand the splitting of the signal of the abovementioned protons almost disappear what makes the binding of the fourth silver ion to the nitrogen of the second terminal macrocyclic ring very probable (Fig. 4e). The relatively lower values of the stability constants  $\text{Ag}_3\text{L}$  ( $\log \beta = 2.75$ ) and  $\text{Ag}_4\text{L}$  ( $\log \beta = 2.89$ ) in comparison with  $\text{Ag}_2\text{L}$  system

**Fig. 4** Schematic way of silver ions binding for **L1**.

**Fig. 5**  $^{31}\text{P}$  NMR spectrum for  $\text{Ag}_2\text{L}$  system of ligand **L1** in methanol.

( $\log \beta = 3.55$ ) is strictly connected with the withdrawal of the electrons from the terminal macrocyclic rings by silver ions bound by sulfur donor atoms from the bridging parts of the ligand. Aziridine substituents are rather not involved in enhancing the metal ion binding – there are no shifts within the region of  $\text{CH}_2\text{-N}$  protons. In case of the second derivative with pyrrolidine moieties **L2**, again one can observe the tendency toward the supporting of the metal ion binding when forming  $\text{Ag}_3\text{L}$  and  $\text{Ag}_4\text{L}$  systems. Such behaviour result in the higher stability constants for  $\text{Ag}_3\text{L}$  and  $\text{Ag}_4\text{L}$  –  $\log \beta = 3.83$  and 3.17 respectively.

**Fig. 6**  $^1\text{H}$ - $^{31}\text{P}$  HMBC spectrum for ligand **L1** in methanol, the signal connected with the protons of  $\text{CH}_2\text{S}$  group connected with silver ions binding in  $\text{Ag}_2\text{L}$  system was marked by rectangle.

**Fig. 7**  $^1\text{H}$ - $^{31}\text{P}$  HMBC spectrum for ligand **L4** in methanol, the signal connected with the protons of  $\text{CH}_2\text{S}$  group connected with silver ions binding in  $\text{AgL}$  system was marked by rectangle.

On the basis of the spectrometric results for **L4** derivative and its complexes with silver ion we can conclude that the way of complexation especially when forming of  $\text{AgL}$ ,  $\text{Ag}_2\text{L}$  and  $\text{Ag}_3\text{L}$  system, is slightly different. In the case of  $\text{AgL}$  complex formation the silver ion is not situated at the centre of the molecule but is rather shifted toward two sulfur donor atoms originated from the bridging moiety of the ligand. Hence this cation is situated asymmetrically, closer to the one of the cyclotriphosphazene subunit. This hypothesis is confirmed by the signal which appears on the  $^1\text{H}$ - $^{31}\text{P}$  HMBC spectrum (3.13–41.4) (Fig. 7). This signal is assigned to  $\text{CH}_2\text{S}$  groups attached to the phosphorous atom from one of the cyclotriphosphazene ring. Proton signals from these groups are shifted of about 0.1 ppm. The additional confirmation of such binding might be also the difference between stability constants of this system for ligands **L2** –  $\log \beta = 6.35$  in which the binding occurs in the centre of the bridging moieties of the molecule and ligand **L4** –  $\log \beta = 5.07$ .

On the spectrum of  $\text{Ag}_2\text{L}$  complex the significant shifts (0.18 ppm) of the signals assigned to protons from  $\text{CH}_2\text{OP}$  group are observed. Such behaviour is connected with different way of binding of the second silver ion to the investigated ligand, as it was observed in case of the ligand **L1**. The shifting of the spectrum in this region is usually connected with the binding of silver ion by endocyclic nitrogen atom from cyclotriphosphazene ring.

The lack of the determined stability constant for  $\text{Ag}_3\text{L}$  doesn't prove that for ligands **L3** and **L4** these forms of

complexes do not exist. Such situation may appear when the constant value is very low and therefore couldn't be determined by the selected potentiometric method.

The very low value of the stability constant may be connected with destabilization of the part of bridged moiety of the ligand to which the first silver ion was connected. Hence the withdrawal of electrons from the cyclotriphosphazene unit is observed thus the second  $\text{N-Ag}^+$  binding is very weak.

After adding the last portion of silver ions, on the  $^1\text{H}$  NMR spectrum there is a split of one of the two multiplets of protons from the  $\text{CH}_2\text{OP}$  group observed, which may be caused by attaching of two silver ions to one of the side macrocyclic part of the ligand.

## Conclusions

Complexes of silver ions with the bridged ligands **L1–L4** show diversity of possible structures which can be formed. The way of binding and the form of the coordination observed depend on the number of preferred donor atoms within the ligand molecule and the steric aspect of the investigated compounds. In case of both presented groups – the bridged ligands **L1–L4** as well as the simpler forms **L5** and **L6**, the most stable form of the complexes with silver ions is the one with stoichiometry equal 1 : 1 ( $\text{AgL}$ ). Despite of different ways of binding the first silver ion – all these systems are characterized by the highest values of stepwise stability constants. The ligands with six sulfur atoms within the structure form more stable systems (for  $\text{AgL}$  system for **L1** and **L2**  $\log \beta$  equals 5.42 and 6.35, respectively) in comparison to those with only four sulfur donor atoms (for  $\text{AgL}$  system for **L3** and **L4**  $\log \beta$  equals 4.16 and 5.07, respectively). The influence of pyrrolidiny and aziridiny substituent groups on the stepwise stability constants is also observed but it depends on the form of the obtained system. In the case of the sandwich type systems the bigger the substituent is, the lower value of the stepwise stability constant of the obtained complexes is observed. In other investigated forms of the complexes the pyrrolidiny substituents enhanced the stability of the observed systems in comparison to the aziridiny derivatives. Due to the possibility of complexation of four silver ions within one molecule and relatively high stability constants of the obtained systems, the synthesized new ligands could be good medium for silver recovering from the industrial wastes. Furthermore the investigated complexes especially with **L5** and **L6** ligands should strengthened the previously described anti-tumor<sup>28</sup> properties of uncomplexed compounds.
