Benzyl bispidine as an efficient replacement for \((-\text{s})\)-sparteine in ring opening polymerisation†

Richard Todd,a Gabriel Rubio,ab Daniel J. Hall,a Sarah Tempelaarab and Andrew P. Dove*a

The synthesis and application of a dibenzyl-functionalized bispidine, in combination with 1-(3,5-bis(trifluoromethyl)phenyl)-3-cyclohexylthiourea (TU) co-catalyst, has been demonstrated to be an excellent catalyst for the controlled ring-opening polymerisation (ROP) of lactide and cyclic carbonate monomers. Notably, the polymerisation proceeds with negligible transesterification or epimerisation, with the polymerisation of stereopure \(\epsilon\)-lactide affording highly crystalline poly(lactide) with a \(T_m\) of 156 °C. ROP of racemic lactide results in the observation of a modest degree of stereocontrol such that the probability of isotactic enchainment, \(P_m = 0.74\). Comparison of a range of alternative hydrogen bond donor co-catalysts revealed that TU displayed the highest polymerisation rates in combination with the dibenzyl-functionalized bispidine.

Introduction

The last decade has led to many advances in organocatalytic ring-opening polymerisation (ROP) of several cyclic monomers, most commonly including esters and carbonates.1–8 On account of their facile access, commercial availability and efficient nature, organic catalysts have become a valuable addition to this field. While several simple species have been reported to mediate these processes, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), triazabicyclodecene (TBD) and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) have become amongst the most active,9–11 diastereomeric thiourea complexes.12,13 The last decade has led to many advances in organocatalytic ring-opening polymerisation (ROP) of several cyclic monomers, notably the polymerisation of stereopure \(\epsilon\)-lactide affording highly crystalline poly(lactide) with a \(T_m\) of 156 °C. ROP of racemic lactide results in the observation of a modest degree of stereocontrol such that the probability of isotactic enchainment, \(P_m = 0.74\). Comparison of a range of alternative hydrogen bond donor co-catalysts revealed that TU displayed the highest polymerisation rates in combination with the dibenzyl-functionalized bispidine.

the derivation of synthetic replacements may enable more highly active and stereoselective analogues to be realised.

These challenges to obtaining (−)-sparteine have led to the investigation of synthetically simple analogues. Aided by computational modelling, Hedrick and co-workers recently identified several commercially available tertiary amines that displayed similar nitrogen–nitrogen spacing (~3 Å) and lone pair orientations to (−)-sparteine.28 Of the tertiary amines selected, tris[2-dimethylamino]ethylamine (Me6TREN) and 1,4,7-trimethyl-1,4,7-triazacyclononane (TACN), in combination with TU, proved the most effective co-catalysts in the ROP of lactide. While TACN displayed comparable polymerization kinetics to (−)-sparteine, transesterification was noted to occur rapidly upon complete conversion of the monomer. Application of Me6TREN led to better polymerisation control albeit at a slightly longer polymerisation time.

We hypothesised that a closer structural analogue to (−)-sparteine would lead to more comparable behaviour in ROP, and hence targeted the preparation of analogous bispidines. Herein we report the improved synthesis of a dibenzyl-functional bispidine, chosen for its identical backbone and similar basicity (pKₐ = 21.25) to (−)-sparteine in addition to its apparent ease of synthesis,17 and explore its activity in the ROP of lactide, comparing directly to that of (−)-sparteine and Me6TREN. Extension of the application of this species with a range of co-catalysts and other monomer feedstocks is also demonstrated.

Results and discussion

Bispidine synthesis and lactide ROP

The synthesis of benzyl bispidine has been reported previously by two different synthetic routes. While one route involves a double Mannich reaction of 1-benzyl-4-piperidone followed by a Wolff–Kishner reduction with hydrazine,19 on account of the broader substrate versatility, we preferred to apply the alternative four step synthetic route reported by Gogoll et al. starting from dimethyl malonate, 3 (Scheme 1).17,22 Following the Knoevenagel condensation of 3 with paraformaldehyde, reduction of the resulting adduct using LiAlH₄ yielded the tetralcohol species, 5. Iodination of 5 as previously reported proved to be problematic on large scales and hence bromination with phosphorous tribromide was undertaken.25 The crude product could be readily purified by passing through a silica plug to obtain 6b as a white solid in 61% yield. Reaction of 6b with excess benzyl amine enabled the isolation of pure bispidine, 2, after flash column chromatography using a selective gradient solvent system.

The ROP of L-lactide, LA, using 10 mol% TU and 5 mol% 2, was studied in CDCl₃ ([La]₀ = 0.7 M) at ambient temperature using 1-phenylethanol as the initiator at a monomer-to-initiator ratio of 50 ([Me₆TREN]/[I]₀ = 50). Monitoring the polymerisation by ¹H NMR spectroscopy revealed that it had reached 87% monomer conversion after only 81 min. Analysis of the resultant polymer by gel-permeation chromatography (GPC) revealed a number average molecular weight (Mₙ) of 13.4 kg mol⁻¹ with a narrow dispersity (D_M = 1.08). Under the same conditions, polymerisation of L-LA with (−)-sparteine and Me₆TREN in place of 2 reached 93% and 92% monomer conversion after 66 and 450 min respectively with similar molecular parameters for the resulting PLA observed by GPC analysis (Table 1). To more precisely compare catalyst reactivities, kinetic studies of LA ROP for each catalyst system were investigated in triplicate (Fig. 2). First order kinetic plots of ln([M]₀/[M]ₜ) against time reveal a linear correlation, with apparent rate constants (K_app) calculated as 1.35 h⁻¹, 2.53 h⁻¹ and 0.38 h⁻¹ for 2, (−)-sparteine and Me₆TREN in combination with TU respectively. Under these conditions, while the bispidine catalyses lactide ROP at a lower rate than (−)-sparteine, the polymerisation occurs almost four times faster then when Me₆TREN is applied.

*a Conditions: 1 ml of CDCl₃ at room temperature; [1-LA] = 0.7 M; 1-phenylethanol as initiator; 5 mol% tertiary amine; 10 mol% of TU; [Me₆TREN]/[I]₀ = 50. Determined by ¹H NMR spectroscopy. 'Determined by GPC analysis in CHCl₃.
The controlled nature of the benzyl bispidine-catalysed polymerisation was further verified by the linear correlation between $M_n$ values obtained by GPC and the monomer conversion determined by $^1$H NMR spectroscopy (Fig. 3a) and the $[M]/[I]$ ratio (Fig. 3b). The resultant PLAs all displayed narrow dispersities (1.18–1.03, Table 2) which indicates that minimal transesterification is occurring. Further analysis of the resultant polymers by matrix-assisted laser desorption ionisation time of flight mass spectrometry (MALDI-ToF MS) revealed only single distributions with spacings of 144 m/z between neighbouring peaks (Fig. 4). The absence of a second distribution with spacings of 72 m/z is consistent with the absence of transesterification side reactions.

Thermal analysis of PLLAs with a degree of polymerisation (DP) of 100 synthesised using TU with both 2 and $(-)$-sparteine observed a melting temperature, $T_m$, of 156 and 158 °C respectively. These match the previously reported melting points for isotactic PLLA prepared using $(-)$-sparteine.$^{34,35}$ In combination with the observation of a singlet resonance in both the homonuclear decoupled $^1$H NMR and $^{13}$C NMR spectra of PLLA synthesised in this manner, these observations confirm the absence of stereo errors, and hence an absence of epimerisation, with identical levels resulting from both $(-)$-sparteine and 2 catalysed polymerisations.$^{36–39}$

ROP of rac-lactide was undertaken to determine if any stereoselectivity would be observed using the catalyst combination of TU and 2. Despite the absence of stereogenic centres in 2, unlike $(-)$-sparteine, analysis of a DP100 poly[rac-lactide] by homonuclear decoupled $^1$H NMR spectroscopy enabled the calculation of the probability of isotactic enchainment, $P_m$, to be 0.74, clearly demonstrating a preference to produce isotactic PLA from the racemic monomer mixture. This is comparable to that observed for rac-LA ROP with $(-)$-sparteine–TU which resulted in a $P_m = 0.74$ (literature value: $P_m = 0.77$).$^{16}$

**Variation of the hydrogen bond donor co-catalyst**

Several hydrogen bond donor alternatives to the thiourea co-catalyst (TU) have been reported over recent years that are successfully used in conjunction with $(-)$-sparteine (Fig. 5).$^{18–22}$ In order to assess the efficiency of these co-catalysts in

![Fig. 3](image-url)

conjunction with the dibenzyl-functional bispidine, 2, in comparison to the initially reported system, we studied their activity for the ROP of L-lactide.

The ROP of L-lactide, LA, using 5 mol% 2 with 10 mol% hydrogen bond donor co-catalyst was again studied in CDCl₃ ([LA]₀ = 0.7 M) at ambient temperature using 1-phenylethanol as the initiator at a monomer-to-initiator ratio of 50 ([M]₀/[I]₀ = 50). The limited solubility of 11 in chloroform required its application at the lower molar ratio of 5 mol% (in preference to the standard 10 mol%). To provide an accurate comparison, polymerisations using co-catalyst TU were also undertaken at 5 mol% loading. Kinetic studies for each catalyst system were investigated in triplicate by monitoring monomer conversion against time using ¹H NMR spectroscopy. First order kinetic analysis of the molecular parameters of the resultant polymers revealed low dispersity values which suggests that the polymerisations were well controlled (Table 3).

In each case, analysis of the molecular parameters of the polymerisations were well controlled (Table 3).

Notably however, co-catalyst 12 resulted in PLLA with lower molecular weight than predicted from the [M]₀/[I]₀ ratio. MALDI-ToF MS analysis of this polymer revealed two distinct distributions, both displaying the expected 144 m/z spacing for the monomer repeat unit. A molecular weight difference of ~40 m/z was observed between the distributions. One of these distributions revealed values that correspond to sodium-charged polymer chains initiated from 1-phenylethanol as expected, however the other distribution showed values revealed that correspond to sodium-charged polymer chains initiated from the co-catalyst 12, which possibly contributes to the increased observed rate of polymerisation. In the case of 9, in which two CF₃ substituents are present on the phenol ring, co-catalyst initiation was not observed which suggests that the phenol in 9 is appropriately activated to only undertake hydrogen bonding and not serve as a source of initiation in the polymerisation.

Interestingly, ¹H NMR spectroscopic analysis of the polymer produced using 2/8 as co-catalysts for the ROP of L-LA revealed a number of overlapping quartets in the range of 5.10–5.25 ppm, consistent with the epimerisation of the monomer during the polymerisation. Despite the previous report of the ROP of L-LA using (−)-sparteine/8 proceeding in the absence of

epimerisation, in our hands, comparable $^1$H NMR spectra of the resultant polymers were also obtained for this system.

**ROP of cyclic carbonates**

To further investigate the versatility of the 2-TU binary catalyst system, polymerisations were undertaken of the 6-membered cyclic carbonates, trimethylene carbonate (TMC) and 5-methyl-5-allyloxycarbonyl-1,3-dioxan-2-one (MAC) of which the (−)-sparteine-TU system has previously demonstrated well controlled homopolymerisation. Polymerisations were carried out under conditions published in literature, using both 2 and (−)-sparteine in combination with TU as catalysts with a target $[M]_0/[I]_0 = 50$ for TMC and 20 for MAC.

The ROP of TMC was performed using 5 mol% of 2 or (−)-sparteine with 5 mol% TU. After ca. 70 h $^1$H NMR spectroscopic analysis of the polymerisation mixtures revealed monomer conversions >90% (Table 4). GPC analysis of the resultant polymers was carried out under conditions published in literature, using both 2 and (−)-sparteine and dispersity was maintained. In conclusion, benzyl bispidine has proven to be a versatile catalyst and an excellent replacement for (−)-sparteine.
