# A trinuclear Zn<sub>3</sub>(OAc)<sub>4</sub>-3,3'-bis(aminoimino)-binaphthoxide complex for highly efficient catalytic asymmetric iodolactonization†

Takayoshi Arai,\* Noriyuki Sugiyama, Hyuma Masu, Sayaka Kado, Shinnosuke Yabe and Masahiro Yamanaka

A 3,3'-bis(aminoimino)BINOL ligand was newly designed and synthesized for the formation of a trinuclear Zn complex upon reaction with  $Zn(OAc)_2$ . Using the harmony of the tri-zinc atoms, 1 mol%  $Zn_3(OAc)_4$ -3,3'-bis(aminoimino)binaphthoxide catalyzed asymmetric iodolactonization in up to 99.9% ee.

In nature, many metalloenzymes containing multiple metal centers show remarkable catalytic activity not observed in non- or monometallic active sites. The multiple metal ions in the multinuclear metalloenzymes act cooperatively to produce maximum activity. For example, phosphatidylcholine-preferring phospholipase C from Bacillus cereus (PC-PLCBc) catalyzes the hydrolysis of phospholipids. The active site of PC-PLCBc contains three Zn<sup>2+</sup> ions, and the multiple zinc atoms are bridged by Asp122 and a water (or hydroxide) molecule. Employing multi-nuclear cooperative effects also becomes an important concept for the design of artificial "catalysts", after pioneering works on the development of lanthanide-containing heterobimetallic asymmetric catalysts.3 While the bimetallic system in asymmetric catalyses has typically been produced using the force of self-assembly, the rational design of tri- or higher multinuclear complexes is still difficult even in cutting-edge chemistry. Here, we report a designer multinuclear metal catalyst for catalyzed asymmetric iodolactonization.

Iodolactonization,<sup>4-10</sup> a type of halolactonization,<sup>11-13</sup> represents a powerful synthetic tool for generating iodine-functionalized cyclic compounds in a single reaction. The resulting iodolactones are both versatile and useful, and have applications as synthetic intermediates in the total synthesis of natural products, as well

Based on the mononuclear L1–Ni(OAc)<sub>2</sub> catalyst, the imidazolidine ligand L2, with a chiral BINOL-backbone, was designed for a dinuclear metal complex. 3,3'-bis(imidazolidine)BINOL L2, prepared *in situ* by the condensation of monobenzyl (R,R)-diphenylethylenediamine with (R)-3,3'-formylbinaphthol, was applied to complex formation using 2 equiv. of metal acetate. In the asymmetric iodolactonization of

as in the production of biologically significant pharmaceutical compounds and agricultural chemicals. Jacobsen pioneered an organo-catalytic version of a useful asymmetric iodolactonization reaction using an urea catalyst.<sup>4</sup> More recently, Johnston reported an asymmetric iodolactonization catalyzed by a bis(amidine) (BAM)-based Brønsted acid.<sup>5</sup> Within the limited examples of metal-catalyzed asymmetric iodolactonization, Gao reported the use of a mononuclear Co-salen complex as a Lewis acid catalyst for asymmetric iodolactonization.<sup>8,9</sup> We have also reported an asymmetric iodolactonization strategy using a newly developed PyBidine(L1)-Ni(OAc)<sub>2</sub> catalyst.<sup>10</sup> The designer chiral ligands are prepared to form a *multinuclear* metal catalyst for use in asymmetric iodolactonization, through the story described in Scheme 1.

Communication ChemComm

5-phenylhex-5-enoic acid (1a), although the L2-Ni(OAc)<sub>2</sub> 1:2 complex gave iodolactone 2a with 41% ee, the L2-Zn(OAc)2 1:2 complex drastically improved the optical yield of 2a to 98% ee. The diastereomeric 3,3'-bis(imidazolidine)BINOL, derived from (S,S)-diphenylethylenediamine with (R)-3,3'-formylbinaphthol, gave a 92% yield of 2a with 85% ee. The successful development of an efficient asymmetric catalyst encouraged further study to determine the structure of the L2-Zn(OAc)<sub>2</sub> complex. The <sup>1</sup>H-NMR study revealed that both L2 and the L2-Zn(OAc)<sub>2</sub> 1:2 complex existed as complex mixtures. The isolation of pure L2 required great effort, but using the 1:2 Zn(OAc)<sub>2</sub> catalyst with isolated L2 gave 2a with a significantly lower selectivity of 62% ee compared to that obtained using the catalyst generated in situ. The imidazolidine ring of L2 prepared in situ was hypothesized to be in equilibrium with the opened aminoimino-form as shown in Scheme 2a, meaning that the 3,3'-bis(aminoimino)BINOL is a promising candidate for providing an effective Zn(OAc)2 catalyst.

To eliminate the cyclized imidazolidine from the equilibrium, the 3,3'-bis(tert-aminoimino)BINOL ligand (L3) in Scheme 2b was redesigned. The newly designed L3 can capture two or three metals in the flexible bis(aminoimino)binaphthol pocket.<sup>14</sup> Reaction of (R)-3,3'-formylbinaphthol and (1R,2R)-2-(isoindolin-2-yl)-1,2-diphenylethan-1-amine (A)15 in ethanol proceeded smoothly at 80 °C to form the imine, and a cold ethanol wash of the resulting precipitate gave L3 as the sole product. <sup>16</sup> The effect of changing the ratio of Zn(OAc)<sub>2</sub> to L3 on catalyst performance was examined in Table 1. With an L3:Zn(OAc)<sub>2</sub> ratio of 1:1 to 1:3, the iodolactone 2a was produced with 99% ee (entries 1-3). However, stopping the reaction within 2 h revealed that a 1:1 L3:Zn(OAc)2 ratio resulted in a slower reaction than using 1:2 or 1:3 ratios. The catalytic activity of several analogs was also investigated in Table 1. The diastereomer of L3 (L4) only gave 68% ee of 2a (entry 4). When one aminoimino functional group was eliminated from L3, the L5-Zn(OAc)<sub>2</sub> catalyst yielded a product with 89% ee, although catalytic activity was significantly reduced (entry 5). Removal of the axial chirality of the binaphthyl skeleton resulted in a trace amount of 2a (entry 6). These results suggest that at least one set of zinc atoms, existing at the appropriate position, harmonizes cooperatively to produce iodolactones in a highly enantioselective manner.

Results of investigations into the scope and generalization of the catalytic asymmetric iodolactonization are shown in Table 2.

Using 1 mol% L3-Zn<sub>3</sub>(OAc)<sub>4</sub> catalyst, a variety of 5-arylhex-5enoic acid substrates were converted quantitatively to the corresponding chiral gluconolactones with excellent enantioselectivity.

<sup>a</sup> 0.1 mol% catalyst was used. <sup>b</sup> 5 mol% catalyst was used. <sup>c</sup> The solvent was toluene:  $CH_2Cl_2 = 4:1$ .

For example, the p-trifluoromethyl-substituted compound was obtained in 99.9% ee (entry 6). The relatively less reactive substrate, having an o-substituent on the benzene ring, was used with 5 mol% catalyst to give the product in >99% yield with 99.4% ee (entry 9). The reaction of 4-phenylpent-4-enoic acid gave the  $\gamma$ -butyrolactone with 87% ee (entry 11). 5-Cyclohexylhex-5-enoic acid was also transformed successfully with 99.3% ee (entry 12). It should be emphasized that only 0.1 mol% L3-Zn3(OAc)4 catalyst gave 98% ee of 2a with a quantitative yield (entry 2).

For accessing the catalytic structure of the L3-Zn(OAc)2 complex, ESI-MS analysis of the catalyst solution suggested the presence of a multi-nuclear zinc complex (Fig. 1). An ion peak at m/z = 1028.3031 attributed to  $[L3_2-Zn_3]^{2+}$  was observed,

ChemComm Communication

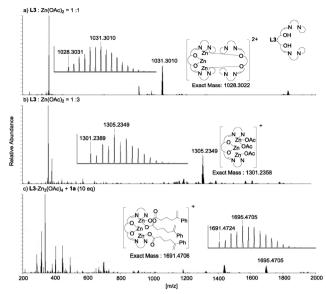

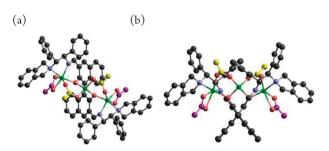

Fig. 1 ESI-MS spectra of (a)  $\mathbf{L3}$  +  $Zn(OAc)_2$  (1:1), (b)  $\mathbf{L3}$  +  $Zn(OAc)_2$  (1:3), and (c)  $\mathbf{L3}$ - $Zn_3(OAc)_4$  +  $\mathbf{1a}$  (1:10).

even when mixing L3 and  $Zn(OAc)_2$  in a 1:1 ratio. When L3 and  $Zn(OAc)_2$  were mixed in a 1:3 ratio, ESI-MS analysis showed a new peak at m/z = 1301.2389, which suggested the formation of a trinuclear zinc complex with L3.

A single crystal was obtained from the reaction of the 1:3 mixture of L3 and  $Zn(OAc)_2$  in methanol, and X-ray crystallographic analysis revealed the structure of the complex to be trinuclear  $Zn_3(OAc)_4$ -3,3'-bis(aminoimino)binaphthoxide, as shown in Fig. 2.

In L3–Zn<sub>3</sub>(OAc)<sub>4</sub>, the two end zinc atoms make the complex hexa-coordinated, and the central zinc atom is part of a tetrahedral coordination sphere. For complex formation, one Zn(OAc)<sub>2</sub> reacted with L3 to give the central zinc binaphthoxide, and the two remaining Zn(OAc)<sub>2</sub> were coordinated, one at each end, by the aminoimino functionality of L3. Alternatively, both end zinc atoms formed a mixed acetoxy-binaphthoxide, and the central zinc remained as Zn(OAc)<sub>2</sub>. Because X-ray crystallography and DFT calculations of L3–Zn<sub>3</sub>(OAc)<sub>4</sub> suggest  $\sigma$ -bond characteristics of the central zinc with phenolic oxygens, complex formation could be explained *via* zinc-binaphenoxide [Zn–O: 1.949(3) or 1.962(3) Å]. In the L3–Zn<sub>3</sub>(OAc)<sub>4</sub> complex, each of the acetoxy anions bridges

**Fig. 2** X-ray crystallographic analysis of the trinuclear  $Zn_3(OAc)_4$ -3,3′-bis(aminoimino)binaphthoxide complex (**L3**– $Zn_3(OAc)_4$ ): (a) the side view, and (b) the front view of the complex. Yellow and purple colored atoms are coordinated acetyl carbons. Hydrogen atoms and solvent molecules are omitted for clarity.

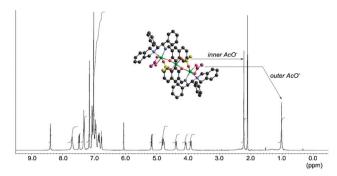

Fig. 3  $^{1}\text{H-NMR}$  spectrum of the  $\textbf{L3-Z}n_{3}(\text{OAc})_{4}$  complex in toluene-d<sub>8</sub> at  $-40~^{\circ}\text{C}.$ 

the central zinc and the end zinc atoms, which restricts the conformation of the L3–Zn $_3$  complex. The isolated crystalline Zn $_3$ (OAc) $_4$ -3,3′-bis(aminoimino)binaphthoxide produced a clean  $^1$ H-NMR spectrum at -40 °C (Fig. 3) and 1 mol% catalyst promoted the asymmetric iodolactonization to give **2a** with 99% ee.

Regarding the catalytic role of L3-Zn<sub>3</sub>(OAc)<sub>4</sub>, after mixing L3-Zn<sub>3</sub>(OAc)<sub>4</sub> and 10 equiv. of 1a, all acetoxy anions of L3- $Zn_3(OAc)_4$  were replaced with **1a** to give the ion peak at m/z =1691.4724, corresponding to  $[L3-Zn_3(CO_2(CH_2)_3C(CH_2)Ph)_3]^+$ (Fig. 1c). This exchange suggests that the zinc-carboxylate of 1a is generated by the L3-Zn<sub>3</sub>(OAc)<sub>4</sub> catalyst as a vital intermediate in the highly enantioselective iodolactonization reaction. However, two types of acetoxy anions were observed in the <sup>1</sup>H-NMR spectrum of L3-Zn<sub>3</sub>(OAc)<sub>4</sub>, at 1.02 and 2.22 ppm. The up-field peak was assigned by the DFT-GIAO calculation to the outer acetoxy anions indicated in purple. Because the peak at 1.02 ppm becomes broader than the peak at 2.22 ppm, the outer acetoxy anions would smoothly accept the exchange with substrate 1a. Based on these experimental analyses on the interaction of L3-Zn<sub>3</sub>(OAc)<sub>4</sub> with 1a, a plausible transition state for the L3-Zn<sub>3</sub>(OAc)<sub>4</sub>-catalyzed iodolactonization is proposed by DFT computed molecular modeling (Fig. 4).<sup>17</sup>

The zinc-carboxylate of **1a** is generated on the outer zinc atom. In the cyclic transition state of the iodolactonization, the benzene ring of **1a** keeps away from the naphthyl ring of **L3** to avoid the steric repulsion observed in **TS2** (the red curves in Fig. 4). From the **TS1** depicted in Fig. 4, the stereoselective formation of (*R*)-iodolactone **2a** is explained well. Because multiple zinc atoms are important for getting high catalytic

Communication ChemComm

activity as shown in Table 1, the central zinc atom would also contribute to enhancing the zinc-carboxylate formation of 1a and/or to accelerating the nucleophilic cyclization of the zinccarboxylate.

In conclusion, using a newly designed 3,3'-bis(aminoimino)-BINOL ligand, the trinuclear Zn<sub>3</sub>(OAc)<sub>4</sub>-3,3'-bis(aminoimino)binaphthoxide complex (L3-Zn<sub>3</sub>(OAc)<sub>4</sub>) was prepared. The harmony of the tri-Zn centers in L3-Zn<sub>3</sub>(OAc)<sub>4</sub> showed outstanding catalytic activity for the iodolactonization reaction to yield products in quantitative yields with excellent enantioselectivity. 18
