The reaction of the 17e nickel(I) radical  $[\text{CpNi}(\text{IDipp})]$  (**1**, IDipp = 1,3-bis(2,6-diisopropylphenyl)imidazolin-2-ylidene) with  $\text{P}_4$  results in a nickel tetraphosphide  $[(\text{CpNi}(\text{IDipp}))_2(\mu-\eta^1:\eta^1:\text{P}_4)]$  with a butterfly- $\text{P}_4^{2-}$  ligand; related chalcogenides  $[(\text{CpNi}(\text{IDipp}))_2(\mu-\text{E}_2)]$  ( $\text{E} = \text{S}, \text{Se}, \text{Te}$ ) and  $[(\text{CpNi}(\text{IDipp}))_2(\mu-\text{E}_3)]$  ( $\text{E} = \text{S}, \text{Se}$ ) are formed with  $\text{S}_{\infty}$ ,  $\text{Se}_{\infty}$  and  $\text{Te}_{\infty}$ .

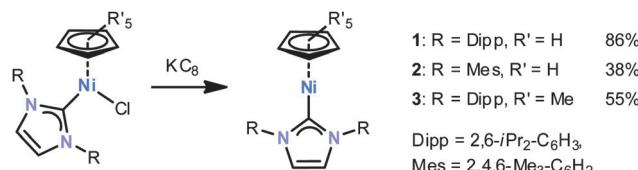

The  $\text{P}_4$  molecule is the most reactive allotrope of phosphorus; its activation and transformation by transition metal compounds has attracted substantial interest over the years.<sup>1</sup> While many low-valent metal complexes, *e.g.* transition metal carbonyls or anionic metalates, react with  $\text{P}_4$ , it is still challenging to design highly selective transformations.<sup>2,3</sup>

White phosphorus is able to efficiently trap organic and main group element radicals.<sup>4</sup> Therefore, one potential solution to the selectivity issue is to use a radical pathway in transition metal-mediated  $\text{P}_4$  transformations. While 2nd and 3rd row metalloradicals are well-established,<sup>5</sup> nickel(I) radicals have attracted significant attention recently.<sup>6,7</sup> Importantly, Driess *et al.* have shown that reactions of  $\beta$ -diketiminato nickel(I) complexes with  $\text{P}_4$  yield dinuclear complexes  $[(\text{L}^{\text{R}}\text{Ni})_2(\mu-\eta^3:\eta^3:\text{P}_4)]$  ( $\text{L}^{\text{R}} = \text{HC}[\text{CMeN}(2,6-\text{R}_2\text{C}_6\text{H}_3)]_2$  with  $\text{R} = \text{Et}, \text{iPr}$ ).<sup>8</sup> The P–P bond activation in the doubly  $\eta^3$ -coordinated ligand is reversible and occurs without the reduction of  $\text{P}_4$  to formally  $\text{P}_4^{2-}$ .

We have been interested in designing new reactive nickel(I) radicals for element–element bond activations. We now report the synthesis of complexes **1–3** featuring an NHC and a

## Selective $\text{P}_4$ activation by an organometallic nickel(I) radical: formation of a dinuclear nickel(II) tetraphosphide and related di- and trichalcogenides<sup>†‡</sup>

Stefan Pelties,<sup>a</sup> Dirk Herrmann,<sup>a</sup> Bas de Bruin,<sup>b</sup> František Hartl<sup>c</sup> and Robert Wolf<sup>\*a</sup>

Scheme 1 Synthesis of nickel(I) complexes **1–3**.

cyclopentadienyl ligand, and an initial reactivity study of complex **1** with  $\text{P}_4$  and related small molecules.

Complexes **1–3** are accessible according to Scheme 1 by the reduction of the appropriate nickel(II) halides with  $\text{KC}_8$  in THF.<sup>¶</sup> <sup>1</sup>H NMR monitoring shows that **1–3** are formed very selectively; they can be isolated as yellow crystalline solids in modest to high yields. Single X-ray structure analyses (ESI<sup>‡</sup>) revealed that the nickel centre is surrounded by the carbene carbon and one  $\eta^5$ -coordinated Cp or Cp\* moiety. No further significant interactions between nickel and the diisopropylphenyl groups are apparent. Nonetheless, the cyclopentadienyl ligand is tilted with respect to the nickel carbene bond with an angle C<sub>carbene</sub>–Ni–(C<sub>5</sub>R<sub>5</sub>)<sub>centroid</sub> of 154.3(1) $^\circ$  for **1**, 151.9(1) $^\circ$  for **2** and 164.6(1) $^\circ$  for **3**.

Cyclic voltammograms show one electrochemically quasi-reversible wave at  $E_{1/2} = -1.02$  and  $-1.06$  V vs. Fc/Fc<sup>+</sup> for Cp-substituted **1** and **2**, respectively, and a reversible wave at  $-1.18$  V vs. Fc/Fc<sup>+</sup> for the Cp\* complex **3** (ESI<sup>‡</sup>). UV-vis-spectroelectrochemistry (see Fig. 1 for **1**) confirms that these processes correspond to chemically reversible oxidations of neutral **1–3** to stable cationic nickel(II) complexes, which probably bind THF in the case of **1** and **2**. Indeed, the preparative oxidation of **1** with [Cp<sub>2</sub>Fe]PF<sub>6</sub> affords the THF adduct  $[(\text{C}_5\text{H}_5)\text{Ni}(\text{IDipp})(\text{THF})]\text{PF}_6$  (**1-THF**) (ESI<sup>‡</sup>).

Complexes **1–3** show identical magnetic moments of 2.3(1), 2.3(1), and 2.2(1)  $\mu_{\text{B}}$  in [D<sub>8</sub>]THF, which indicate the presence of one unpaired electron per molecule. The EPR spectrum of **1** is characteristic for an  $S = 1/2$  system and reveals a rhombic g-tensor with significant deviations from  $g_e$  pointing to metalloradical character. DFT calculated  $g_{11}$  and  $g_{22}$  values are somewhat smaller than the experimental ones, but show a similar rhombicity (Fig. 1).

**Fig. 1** Left: UV/Vis monitoring of the oxidation of **1** performed at  $-0.83\text{ V}$  vs.  $\text{Fc}/\text{Fc}^+$  within an OTTLE cell equipped with a Pt minigrid working electrode, THF/TBAH under Ar, 293 K. Right: experimental and simulated X-band EPR spectrum of **1** in frozen THF. Freq. 9.3646 GHz, 0.063 mW, 20 K, mod. 4 Gauss;  $g$ -tensor parameters obtained from simulations and DFT calculations (b3-lyp, def2-TZVP) are:  $g_{11} = 2.377$  (2.220),  $g_{22} = 2.306$  (2.187),  $g_{33} = 2.050$  (2.078) (DFT-calculated values in parentheses).

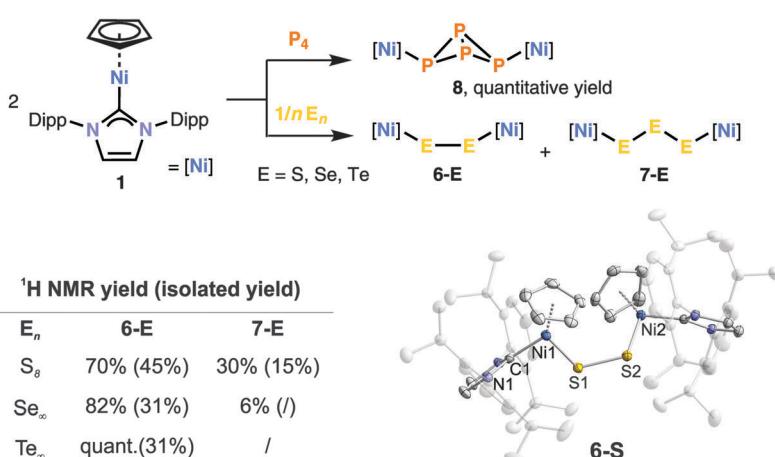

**Fig. 2** Reaction of **1** with TEMPO and solid-state molecular structure of  $[(\text{C}_5\text{H}_5)\text{Ni}(\text{TEMPO})(\text{IDipp})]$  (**5**). The hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at 40% level. Selected bond lengths [ $\text{\AA}$ ] and angles [ $^\circ$ ]: Ni1–O1 1.8408(14), Ni1–N1 1.9581(16), N1–O1 1.3989(20), Ni1–C1 1.8824(19), Ni1–C4 2.034(2), C1–Ni1–O1 104.50(7), O1–Ni1–N1 43.07(6), C1–Ni1–C4 97.104(4), N1–Ni1–C4 115.325(2).

Initial reactivity studies of **1** established its behavior as a typical metal-centered radical. The reactions of phenyl disulfide

and TEMPO with **1** in THF afforded the known thiolate  $[(\text{C}_5\text{H}_5)\text{Ni}(\text{SPh})(\text{IDipp})]$  (**4**)<sup>9</sup> and the new TEMPO adduct **5** in quantitative yield (Fig. 2). The molecular structure of **5** shows a side-on  $\eta^2$ -coordinated TEMPO ligand and an  $\eta^1$ -coordinated Cp ligand at the distorted square planar nickel(II) atom. The structural parameters agree with presence of a formally anionic TEMPO<sup>–</sup> ligand.<sup>10</sup> A sharp  $^1\text{H}$  NMR singlet at 5.93 ppm is observed for the Cp moiety even at  $-90\text{ }^\circ\text{C}$  presumably due to rapid haptotropic migration.

We next investigated the reactivity of **1** with the heavier chalcogens. The reaction with  $\text{S}_8$  (1/8 equivalents) gave the blue disulfide **6-S** and the purple trisulfide **7-S** (Fig. 3) in a 7 : 3 ratio according to  $^1\text{H}$  NMR analysis. **6-S** is soluble in *n*-hexane and diethyl ether and can thus be separated from **7-S** by extraction and subsequent crystallisation (ESI $^\ddagger$ ). Disulfide-bridged dinuclear complexes with an M–S–S–M motif are well-known,<sup>11</sup> while complexes with an unsupported  $\mu\text{-S}_3^{2-}$  bridge are still rather scarce.<sup>11a,b,12</sup> The structure of **7-S** shows a similar S1–S2–S3 angle and S–S bond lengths as the structure of  $[(\text{C}_5\text{H}_5)\text{Fe}(\text{CO})_2(\mu\text{-S}_3)]$ .<sup>11a</sup> Diselenide **6-Se** (31% isolated) is the major reaction product of **1** with one equivalent of elemental selenium. A  $^1\text{H}$  NMR spectrum of the reaction mixture (THF, room temperature) shows that **6-Se** is formed in more than 80% yield whereas the triselenide **7-Se** is a minor by-product. Ditelluride **6-Te** was the only product to be detected after stirring **1** with one equivalent of grey tellurium for seven days. It was isolated as a dark brown crystalline solid in 31% yield. The molecular structures of **6-Se**, **6-Te** and **7-Se** are analogous to the corresponding sulfides **6-S** and **7-S** (ESI $^\ddagger$ ).

Considering that a mixture of at least two products is formed with sulfur and selenium, it was gratifying to discover that complex **1** reacts with  $\text{P}_4$  in a highly selective fashion in THF at room temperature, giving tetraphosphide **8** as the sole product. The reaction is instantaneous, and compound **8** can be isolated as an analytically pure, dark purple powder in quantitative yield simply by removing the solvent. Its molecular structure (Fig. 3)

**Fig. 3** Left: reactions of **1** with  $\text{P}_4$ ,  $\text{S}_8$ ,  $\text{Se}_\infty$  and  $\text{Te}_\infty$ . Right: solid-state molecular structures of the products **6-S**, **7-S** and **8**. The hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at 40% level. Selected bond lengths [ $\text{\AA}$ ] and angles [ $^\circ$ ]: **6-S**: Ni1–S1/Ni2–S2 2.1800(1)/2.1797(1), S1–S2 2.0476(1), Ni1–S1–S2–Ni2 78.601(5), **7-S**: Ni1–S1/Ni2–S3 2.1936(6)/2.1748(5), S1–S2/S2–S3 2.0561(7)/2.0522(7), S1–S2–S3 111.58(3), **8**: Ni1–P1/Ni2–P2 2.2107(6)/2.2103(6), P1–P3/P4 2.2334(7)/2.2111(7), P3–P4 2.1649(7), P1–P2 2.8897(8).

shows an *exo/exo* configuration for the two  $[(C_5H_5)Ni(IDipp)]$  units. The P–P bond lengths (2.2111(7)–2.2334(7) Å) are very similar to those in  $P_4$  (P–P 2.21 Å). The  $^{31}P\{^1H\}$  NMR spectrum shows two triplets at  $\delta = -307.4$  and  $-45.8$  ppm with  $^1J_{P-P} = -190.5$  Hz. These values are similar to those of  $[\{Cp^RFe(CO)_2\}_2(\mu-\eta^1:\eta^1-P_4)]$  ( $Cp^R = C_5H_3-1,3-tBu_2$ ,  $C_5H_2-1,2,4-tBu_3$ ,  $C_5H-iPr_4$ ,  $C_5Me_5$ ) and  $[\{Cp^*Cr(CO)_3\}_2(\mu-\eta^1:\eta^1-P_4)]$ , which also display a tetraphospho-[1.1.0]bicyclobutane framework.<sup>13</sup>

In conclusion, we have prepared rare mononuclear cyclopentadienyl nickel(i) complexes **1–3** with significant metallo-radical character.<sup>6,7</sup> This feature was successfully utilized for the high-yield synthesis of the novel tetraphosphido complex  $[(C_5H_5)Ni(IDipp)]_2(\mu-\eta^1:\eta^1-P_4)$  (**8**), which features an uncommon  $\mu-\eta^1:\eta^1$ -bridging  $P_4^{2-}$  ligand.<sup>14</sup> Further reactivity studies of **1–3** and **8** are in progress; the results will be reported in due course.

We thank Christian Hoidn, Christian Preischl and Philipp Büschelberger for preparing **1–3** as part of their BSc projects. Financial support by the DFG and NWO (NWO-VICI 016.122.613) is gratefully acknowledged.

## Notes and references

§ During the preparation of this manuscript, Hazari *et al.* reported the synthesis and characterization of **1**, **1**-THF and closely related mono- and dinuclear species by a different synthetic route.<sup>7</sup> Based on DFT calculations, the bending of the C<sub>carbene</sub>–Ni–( $C_5H_5$ )<sub>centroid</sub> angle in the structure of **1** was attributed to the asymmetric spin density distribution.

¶ The hydride complex  $[(C_5H_5)NiH(IDipp)]$  (**1-H**) was identified as a minor by-product (<5%) of the synthesis of **1**. Compound **1-H** was prepared independently and features a distinct molecular structure from **1**; see the ESI‡ for details.
