Synthesis and structural characterisation of Pd(II) and Pt(II) complexes with a flexible, ferrocene-based P,S-donor amidophosphine ligand†

Jiří Tauchman, Ivana Císařová and Petr Štěpnička*

1′-Diphenylphosphino-1-[[2-(methylthio)ethyl]amino]carbonyl[ferrocene (1), accessible via amidation of 1′-(diphenylphosphino)ferrocene-1-carboxylic acid (Hdpf) with 2-(methylthio)ethyl amine, reacts with [PdCl2(cod)] (cod = cycloocta-1,5-diene) at a 1:1 metal-to-ligand ratio to give trans-[PdCl2(1′-κ2P,S)], (trans-2) as the sole product. A similar reaction with [PtCl2(cod)] affords a mixture of cis- and trans-[PtCl2(1′-κ2P,S)] (cis- and trans-3), which can be separated by fractional crystallisation. Complexation reactions performed with 2 equiv. of the ligand are less selective, yielding mixtures of the expected bis-phosphine complexes (i.e., trans-[PdCl2(1′-κP)], or a mixture of cis- and trans-[PtCl2(1′-κP)]) with the respective monophosphine complexes. The structures of 1, trans-2, cis-3 and trans-3 determined by X-ray diffraction demonstrate the ability of the title ligand to act as a flexible cis- or trans-P,S-chelate donor (the ligand bite angles are 174.03(2)/173.05(2)° for trans-2/3 and 92.86(2)° for cis-3).

Introduction

Ligands capable of acting as trans-chelate donors are attractive research targets. They not only represent structurally interesting molecules but are also useful tools for the elucidation of structural effects, reaction mechanisms, etc.1 The most often studied trans-chelating ligands still remain diphosphines, whose donor moieties are brought into appropriate positions with the aid of a rigid organic backbone.1,2 Symmetrical ligands featuring other donor atoms (e.g., N,N-donors3 and bis-carbenes4) and, particularly, their donor-asymmetric counterparts are much less common.

For instance, the rare trans-chelating P,N-donors are represented by pyridyl-phosphines Ph3PC6H4CH2O(CH2)n-(C6H4N-2) (n = 1–3) and by (diphenylphosphino)ferrocene derivatives bearing N-heterocyclic substituents in position 1’ of the ferrocene unit.5 As far as we are aware, however, no similar P,S-bidentate donors have been described in the literature.7

Recently, we found that carboxamides I–IV8–10 (Scheme 1), prepared from 1′-(diphenylphosphino)ferrocene-1-carboxylic acid (Hdpf)11 and simple amines equipped with a donor substituent at the terminal position readily form trans-chelate complexes with palladium(ii) ions. This prompted us to design an analogous, P,S-donor ligand.12 In this contribution, we describe the preparation and structural characterisation of 1′-diphenylphosphino-1-[[2-(methylthio)ethyl]amino]carbonyl-ferrocene (1), a congener of the recently described phosphino-carboxamide13 donors III and IV,10 and Pd(ii) and Pt(ii) complexes obtained thereof.

Results and discussion

Synthesis and characterisation of ligand 1

Phosphino-amide 1 was obtained upon reacting 1′-(diphenylphosphino)ferrocene-1-carboxylic acid (Hdpf) with 2-(methylthio)ethylamine in the presence of a slight excess of 1-hydroxybenzotriazole and 1-ethyl-3-[3-(dimethylamino)-propyl]-carboadiimide as the coupling agents14 (Scheme 2). The
compound was isolated by column chromatography, resulting as an air-stable, rusty orange solid in 84% yield. The chromatography also afforded a small amount of a more polar side-product, which was identified as the corresponding phosphine oxide 1O (isolated yield: 7%).

NMR spectra of 1 and 1O show signals of the terminal SMe groups (δH/δC: 2.16/14.97 for 1, and 2.06/14.96 for 1O) and the ethane-1,2-diy1 linkers. Signals due to the PPh2-substituted ferrocene units are observed at the expected positions and with the characteristic JPC values (cf. ref. 8–10). The 31P NMR shifts are −16.9 and 31.6 for 1 and 1O, respectively. The compounds display typical amide bands (namely νNH and amide I/II bands) in their IR spectra and give rise to pseudomolecular ions in the ESI mass spectra.

The molecular structures of 1 and 1O determined by single-crystal X-ray diffraction analysis are depicted in Fig. 1 and 2. Selected geometric data are given in Table 1. The ferrocene moieties in the molecules of 1 and 1O are regular showing tilt angles below ca. 5° and, accordingly, similar individual Fe–C distances (2.030(2)–2.059(2) Å for 1, and 2.024(2)–2.062(2) Å for 1O). However, their substituents assume different mutual orientations (see τ angles in Table 1). While the conformation of 1 is anticlinal eclipsed, the substituents in 1O are moved closer to a synclinal eclipsed conformation by the intramolecular N–H⋯O–P hydrogen bond. In both cases, the amide planes and the planes of their parent cyclopentadienyl ring are twisted (see φ in Table 1) so that the amide nitrogen is directed towards the side of the ferrocene unit. The amide substituents in 1 and 1O adopt similar orientations pointing toward the other Cp ring and have the substituents at the C24–C25 bond at ca. 60° or in gauche conformation.

**Preparation of Group 10 metal complexes**

Divalent Group 10 metal ions were chosen for an evaluation of the coordination properties of compound 1 mainly because they include the borderline Ni(n) as well as the typical soft Pd(n)/Pt(n) metal ions showing different kinetic properties.15,16 Unfortunately, repeated attempts at obtaining some Ni(n)-1 complexes failed. The reactions of [NiCl2(dme)] (dme = 1,2-dimethoxyethane) or NiCl2·6H2O with 1 equiv. of PPh2 substituents, general EDC = 1-ethyl-3-[3-(dimethylamino)propyl]carbodiimide.

resulting from a relatively smaller size of the Ni(n) ion and the soft character of the donor atoms present in 1.

In contrast, the reaction of 1 with [PdCl₂(cod)] (cod = cycloocta-1,5-diene; Pd : n = 1 : 1) proceeded rapidly and cleanly to provide a single product showing its \(^{31}\)P NMR signal at a lower field (\(\delta_{P} = 23.6, \Delta_{P} = 40.5 \text{ ppm}\)) compared with the free ligand. This shift, together with a low-field shift of the SMe resonance (\(\Delta_{H} = 0.13 \text{ ppm}\)) and its splitting with the \(^{31}\)P nucleus (\(J_{\text{PF}} = 4.7 \text{ Hz}\)), already suggested chelate coordination of ligand 1. Indeed, this was corroborated by X-ray crystallography showing the product to be the trans-chelate complex \([\text{PdCl}_{2}(1-\kappa^{2}\text{S,P})]\) (trans-2 in Scheme 3).

Compound trans-2 shows broad \(^{3}H\) NMR signals for protons at the ferrocene unit and in the ethane-1,2-diyl bridge at room temperature.\(^{17}\) Nonetheless, this broadening is in line with the formulation as it reflects a limited molecular mobility resulting from spatial constraints imposed by a tight chelate coordination. The amide vibrations of trans-2 are observed shifted vs. free 1 (amide I and II by ca. +30 and −10 cm\(^{-1}\), respectively) whilst the amide \(^{13}\)C NMR resonance (C = 0) remains nearly unaffected. The complex displays a pseudo-molecular ion ([M + Na]\(^{+}\)) and fragment ions attributable to [M – Cl – HCl]\(^{-}\) and [Pd(Ph\(_{2}\)Pfc)]\(^{+}\) (fe = ferrocene-1,1'-diyl) in its ESI MS spectrum.

An analogous reaction of 1 with [PtCl\(_{2}\)(cod)] (Scheme 3; CHCl\(_{3}\)/refluxing for 3 h) afforded a mixture of two compounds showing different \(^{31}\)P NMR shifts and \(J_{\text{PP}}\) coupling constants. Considering the fact that even the signals of the SMe protons were flanked with \(^{195}\)Pt satellites, the products were formulated as isomeric bis-phosphine complexes, cis- and trans-\([\text{PtCl}_{2}(1-\kappa^{2}\text{P})]\) (5). Likewise cis- and trans-3, the isomers of complex 5, can be clearly differentiated by means of \(^{31}\)P NMR spectroscopy\(^{19a,b}\) (cis-5: \(\delta_{P} = 10.2, J_{\text{PP}} = 3970 \text{ Hz}\); trans-5: \(\delta_{P} = 10.9, J_{\text{PP}} = 2615 \text{ Hz}\)). In accordance with the geometry of the leaving ligand and kinetic inertness of Pt(n) species, the bis-phosphine complexes were formed in cis : trans ratio of ca. 2 : 1 which, however, changed in favour of the thermodynamically preferred trans-isomer after refluxing for 18 h (cis : trans = 1 : 2). When the Pt-precursor was replaced with K[PtCl\(_{3}\)(n\(^{2}\)C\(_{2}\)H\(_{4}\))], whose alkene ligand destabilises the chlorine in mutual trans position owing to its large trans-influence,\(^{20}\) the product ratio determined initially (room temperature/90 min) was inverted (cis : trans = 1 : 2) and did not change upon refluxing for 18 h. Even in this case, however, minor amounts of 1O, cis- and trans-3 were detected in the reaction mixture.

The molecular structures of the Pd(n) and Pt(n) complexes

As indicated above, the structures of trans-2, trans-3 and cis-3 were determined by X-ray diffraction analysis. Only the latter compound was isolated in an unsolvated form while the trans-complexes accommodated molecules of adventitious water (trans-2) or the crystallisation solvent (trans-3) in their structures (for a discussion of the crystal packing, see ESI\(^{\dagger}\)). The molecular structures of cis- and trans-3 are presented in Fig. 3. A structural diagram for trans-2 is available as ESI (Fig. S2\(^{\dagger}\)). Relevant geometric data are summarised in Table 2.

The complexes adopt the expected square-planar geometry so that the central atoms and their four ligating atoms are coplanar within less than 0.001 Å in trans-2, ca. 0.03 Å in trans-3 and ca. 0.16 Å in cis-3. Rather surprisingly, the largest deviation from a coplanar arrangement detected for the latter complex is associated with the smallest departure of the individual inter-ligand angles from the ideal 90° (ca. 88–93°). Inter-ligand angles in the trans-complexes range ca. 83–94°, with the extreme values pertaining to the S–M–Cl1/2 angles.

The M-donor distances are found within the usual ranges,\(^{11}\) yet they nicely demonstrate the different trans-influence of the ligands (PR\(_{3} > SR_{2} > \text{Cl}^{-}\))\(^{10}\) and the fact that two soft donor

\[\text{PdCl}_{2}(\text{cod})\] 

\[\text{PtCl}_{2}(\text{cod})\] or \[K[\text{PtCl}_{3}(\text{C}_{2}\text{H}_{4})] \]
moieties (with a high trans-influence) bonding to a soft metal ion in mutually trans positions destabilise each other.22,23 Thus, the Pt–P and, particularly, the Pt–S bonds are longer in trans-3 than in cis-3,24 while for cis-3, the Pt–Cl distance trans to P is significantly longer than that trans to S. It is also noteworthy that because of practically identical radii of Pd(n) and Pt(n),22 and identical coordination environments, the overall structures of trans-2 and trans-3 are very similar. The M-donor (M = Pd, Pt) bond distances and inter-ligand angles in these complexes differ by no more than ca. 0.03 Å and 1°, respectively.

In order to comply with the demands of the coordinated metal ions, the ligand molecule undergoes a pronounced conformational reorganisation. The major changes are seen at the ferrocene unit, whose substituents are rotated to positions more proximal than in the structure of uncoordinated 1. In trans-2 and 3, the ferrocene units are synclinal eclipsed, and in cis-3 they assume an even closer position near to staggered synclinal. The amide units are also rotated from positions observed in free 1 (by ca. 40°) so that the N atoms are forced away from the ferrocene unit, slightly more in cis-3 than in the trans-complexes. On the other hand, the tilt angles remain rather low, the largest tilting being 5.5(1)° for cis-3. The orientation of the substituents at the C24–C25 are virtually the same as that in the free ligand, but the bond is differently orientated towards the plane of the amide-substituted cyclopentadienyl ring.26 The C–P–C angles and C25–S–C26 angles change only marginally.

**Electrochemistry**

The electrochemical behaviour of ligand 1, phosphine oxide 10 and Pd(n) complex trans-2 was studied by cyclic and differential pulse voltammetry at a glassy carbon disc electrode in 1,2-dichloroethane containing 0.1 M Bu4N[PF6] as the supporting electrolyte.

Compound 1 showed three consecutive oxidations within the accessible potential range (Fig. 4). The first oxidation...
observed at $E_{pa} = 0.28$ V vs. ferrocene/ferrocenium was quasi-reversible. At relatively lower scan rates or when the switching potential was set to more positive values, it appeared electrochemically irreversible. However, when scanned separately and with higher scan rates, a reductive counter-wave could be detected (see inset in Fig. 4).

The subsequent oxidations seen at $E_{pa} = 0.60$ and 0.80 V were also irreversible and probably composite in nature. Their complex nature was manifested in the difference pulse voltammograms (Fig. 5). It is also noteworthy that another wave, partly replacing the first oxidation wave, emerged upon repeated scanning (see Fig. 4, signal marked with an asterisk). Based on a comparison of the redox potentials and in view of our previous work, this wave could be tentatively assigned to the oxidation of 10 resulting from primary, ferrocene-based oxidation and the associated follow-up chemical reactions of the unstable ferrocenium intermediate.

Unlike 1, the redox behaviour of the corresponding phosphine oxide 10 was simple (Fig. 6). The compound, lacking the lone pair of phosphorus as a reactive site, underwent a single, one-electron reversible oxidation at $E^{\circ} = 0.40$ V. The separation of the peaks in cyclic voltammograms was ca. 80 mV at a scan rate of 0.1 V s$^{-1}$. The anodic and cathodic peak currents increased linearly with the square root of the scan rate ($i_p \propto \nu^{1/2}$) and their ratio remained close to unity over the range 0.02–1.0 V s$^{-1}$. This oxidation, attributed to the ferrocene/ferrocenium couple, appeared shifted to more positive potentials than the ferrocene reference, in accordance with the electron-withdrawing nature of the substituents attached to the ferrocene unit (cf. the Hammett’s $\sigma_p$ constants: CONHMMe 0.35, PPh$_2$ 0.19, P(O)Ph$_2$ 0.53) that render the oxidation more difficult.

Similarly to 10, complex trans-2 (Fig. 7) displayed a one-electron, reversible oxidation at $E^{\circ} = 0.46$ V. This wave was...
shifted with respect to the free ligand, most likely owing to an electron density transfer from the ligand (ferrocene unit) upon coordination. An additional irreversible, multi-electron reduction was observed at $E_{pc} = -1.34$ V vs. ferrocene/ferrocenium. Together with an associated, small oxidation wave at $E_{pa}$ ca. $-0.61$ V, this probably reflects an irreversible reductive removal of one Pd-bound chloride as described previously for [PdCl$_2$(PPh$_3$)$_2$].

**Conclusions**

Functional ferrocene-based phosphino-amide 1 is readily accommodated as a P,S-donor in both the cis- and trans-MCl$_3$ square-planar fragments of the heavier Group 10 metal ions. The latter coordination mode appears particularly remarkable because the ligand is structurally flexible and donor-asymmetric, unlike the majority of trans-spanning donors known to date. Furthermore, the results presented earlier for the structurally related ligands I-IV (see Introduction) and herein for compound 1, demonstrate that the formation of trans-chelate complex donors does not necessarily require the prospective trans-spanning donor to comprise a rigid organic backbone if this is replaced with appropriately selected structural fragments. Further work focusing on other metal ions and a comparison of the structurally related donors 1, III and IV is currently underway.

**Experimental**

**Materials and methods**

All manipulations were performed under an argon atmosphere and with the exclusion of direct daylight. Chloroform and dichloromethane were dried by standing over K$_2$CO$_3$ and distilled under argon. Methanol was distilled from MeONa. Solvents (from Lachner) for work-up and crystallisations were distilled under argon. Methanol was distilled from MeONa. Solvents (from Lachner) for work-up and crystallisations were used without any additional purification. Hdpf, MCl$_2$(cod) (M = Pd, Pt), and K[PdCl$_3$(C$_2$H$_4$)] were prepared according to the literature procedures. All other chemicals were obtained from Sigma-Aldrich.

NMR spectra were recorded at 25°C using a Varian UNITY Inova 400 MHz spectrometer operating at 399.95 MHz for $^1$H, at 100.58 MHz for $^{13}$C, and at 161.90 for $^{31}$P, if not specified otherwise. Chemical shifts (δ/ppm) are given relative to internal tetramethylsilane ($^1$H and $^{13}$C) and to external 85% H$_3$PO$_4$ ($^{31}$P). Infrared spectra were recorded with an FT IR Nicolet Magna 760 spectrometer in the range 400–4000 cm$^{-1}$. Electrospary ionisation (ESI) mass spectra were obtained with an Esquire 3000 (Bruker; low resolution) or an LTQ Orbitrap XL instrument (Thermo Fisher Scientific; high resolution).

**Syntheses**

1'-Diphenylphosphino-1'-(2-[2-(methylthio)ethyl]amino)carbonyl)ferrocene (1). A suspension of Hdpf (414 mg, 1.00 mmol) and 1-hydroxybenzotriazole monohydrate (184 mg, 1.20 mmol) in dry dichloromethane (15 mL) was cooled in an ice bath and treated with 1-[3-(dimethylamino)propyl]-3-ethylcarbodiimide (0.21 mL, 1.20 mmol). The resulting mixture was stirred at 0°C for 15 min, whereupon the solids dissolved to give a clear orange-red solution. Then, a solution of H$_2$NCH$_2$CH$_2$SMe (0.12 mL, 1.20 mmol) in dichloromethane (5 mL) was introduced, and the cooling bath was removed. The reaction mixture was stirred overnight at room temperature and then washed successively with saturated aqueous NaHCO$_3$ (2 × 50 mL) and brine (50 mL). The organic phase was separated, dried over MgSO$_4$ and evaporated under vacuum, leaving an orange oily residue which was purified by column chromatography over silica gel using dichloromethane–methanol 50:1 (v/v) as the eluent. Two orange-yellow bands were collected and evaporated to afford analytically pure phosphine 1 as an orange solid (409 mg, 84%; the first band) and the respective phosphine-oxide 1O (yellow-brown solid, 33 mg; 7%; second band).

**Analytical data for 1.** $^1$H NMR (CDCl$_3$): δ 2.16 (s, 3 H, SMe), 2.73 (t, $^1$J$_{HH} = 6.4$ Hz, 2 H, SCH$_2$), 3.57 (q, $^1$J$_{HH} = 6.3$ Hz, 2 H, HNCH$_2$), 4.15 (virtual q, $^1$J$_{HH} = 1.9$ Hz, 2 H, fc), 4.26 (virtual t, $^1$J$_{HH} = 1.9$ Hz, 2 H, fc), 4.48 (virtual $^3$J$_{HH} = 1.8$ Hz, 2 H, fc), 4.61 (virtual t, $^1$J$_{HH} = 2.0$ Hz, 2 H, fc), 6.20 (t, $^1$J$_{HH} = 5.4$ Hz, 1 H, NH), 7.35–7.44 (m, 10 H, PPh$_2$). $^{13}$C$_1$H NMR (CDCl$_3$): δ 14.97 (SMe), 34.00 (SCH$_2$), 37.70 (HNCH$_2$), 69.46 (CH fc), 71.56 (CH fc), 72.86 (d, $^1$J$_{PC} = 3$ Hz, CH fc), 74.38 (d, $^1$J$_{PC} = 13$ Hz, CH PPh$_2$), 76.77 (C-CONH fc), 128.29 (d, $^3$J$_{PC} = 7$ Hz, CH PPh$_2$), 128.77 (CH (PPh$_2$), 133.47 (d, $^1$J$_{PC} = 20$ Hz, CH PPh$_2$), 138.23 (d, $^3$J$_{PC} = 8$ Hz, C$_{ipso}$ PPh$_2$), 169.92 (CONH). [PdCl₂(cod)] (29 mg, 0.10 mmol). The dark red solution formed was stirred for 1 h and filtered through a PTFE syringe filter (pore size 0.45 μm) into pentane (70 mL). After standing at −18 °C overnight, the precipitated product was filtered off, washed with pentane (3 × 5 mL) and dried under vacuum to afford analytically pure complex trans-2 as an orange amorphous solid. Yield: 57 mg, 86%. 1H NMR (CDCl₃, 50 °C): δ 2.29 (d, 4J₁H-P = 4.7 Hz, 3 H, SMe), 3.13 (q, J₂H-P = 5.3 Hz, 2 H, SCH₂), 3.79 (br s, 2 H, HNC₃), 4.32 (virtual t, J = 2.0 Hz, 2 H, fc), 4.72 (s, 2 H, fc), 4.80 (br s, 2 H, fc), 5.36 (virtual t, J = 1.7 Hz, 2 H, fc), 7.32–7.47 (m, 6 H, PPh₂), 7.51 (t, J₁H-P = 5.2 Hz, 1 H, NH), 7.61–7.71 (m, 4 H, PPh₂). 31P{1H} NMR (CDCl₃): δ 23.6 (s). IR (Nujol): ν₁H = 1735 cm⁻¹, ν₂H = 1635 m, ν₃H = 1030 m, 999 w, 975 w, 828 m, 806 w, 763 s, 743 s, 713 m, 698 s, 655 w, 548 w, 527 m, 496 w, 483 s, 440 m, 416 w cm⁻¹. MS [ESI⁺]: m/z 776 [M + Na⁺], 681 [M – HCl – Cl⁻]. Anal. Caled for C₂₆H₂₆NOPSCl₂FePd·0.25CHCl₃ (694.5): C 45.39, H 3.81, N 1.84. Found: C 45.44, H 3.82, N 1.84.

Characterisation data for trans-[PtCl₂(1-k⁺S,P)] (trans-1). 1H NMR (CDCl₃): δ 2.41 (d, 4J₁H-P = 4.2 Hz with br 195Pt satellites, 1J₁H-P = 23.0 Hz, 3 H, SMe), 3.25 (br s, 2 H, SCH₂), 3.83 (br s, 2 H, HNC₃), 4.57 (virtual t, J = 1.9 Hz, 2 H, fc), 4.75 (s, 2 H, fc), 4.82 (br s, 2 H, fc), 5.30 (s, 2 H, fc), 7.35–7.47 (m, 6 H, PPh₂), 7.59 (br t, 1J₁H-P = 5.7 Hz, 1 H, NH), 7.64–7.76 (m, 4 H, PPh₂). 31P{1H} NMR (CDCl₃): δ 6.6 (s with 195Pt satellites, 1J₁P-P = 3959 Hz). IR (Nujol): ν₁H = 3375 m, (M + Na⁺), 681 [(M – HCl – Cl⁻)]. Anal. Caled for C₂₆H₂₆NOPSCl₂FePd·0.25CHCl₃ (753.3): C 41.45, H 3.48, N 1.86. Found: C 41.18, H 3.26, N 1.60.

Attempted reaction of 1 with [NiCl₂(dme)] or NiCl₂·6H₂O. A solution of 1 (15 mg, 0.03 mmol) in absolute ethanol (1 mL) was added to a suspension of [NiCl₂(dme)] (7 mg, 0.03 mmol, dme = 1,2-dimethoxyethane) or NiCl₂·6H₂O (7 mg, 0.03 mmol) in the same solvent (1 mL). The mixture was stirred at room temperature for 1 h. Subsequent evaporation of the mixture caused extensive decomposition.

Reaction of [PdCl₂(cod)] with two equivalents of 1. A solution of 1 (30 mg, 0.06 mmol) in chloroform (3 mL) was added to solid [PdCl₂(cod)] (23 mg, 0.06 mmol) and the resulting red solution was refluxed for 3 h. After cooling to room temperature, the mixture was evaporated under vacuum and the residue was analysed by 1H and 31P{1H} NMR spectroscopy. The spectra showed two sets of signals attributable to Pt⁻₁ species. Separation of the products was achieved by fractional crystallisation as follows.

A chloroform solution (ca. 1 mL) of the crude product was layered with hexane. Subsequent crystallisation at room temperature for several days afforded orange crystals of cis-3, which were filtered off, washed with hexane (3 mL) and pentane (3 × 3 mL) and dried under vacuum. Yield of trans-3: 12 mg, 26%. 1H NMR (CDCl₃): δ 2.52 (s with broad 195Pt satellites, 1J₁H-P = 48.3 Hz, 3 H, SMe), 2.72–2.83 (m, 1 H, SCH₂), 3.51–3.60 (m, 1 H, SCH₂), 4.10–4.23 (m, 2 H, HNC₃), 4.44 (dt, J = 4.0, 1.6 Hz, 1 H, fc), 4.48 (dq, J = 2.7, 1.4 Hz, 1 H, fc), 4.55 (dq, J = 3.8, 1.3 Hz, 1 H, fc), 4.66 (dt, J = 2.6, 1.4 Hz, 1 H, fc), 5.14 (dt, J = 2.7, 1.4 Hz, 1 H, fc), 5.47 (dq, J = 2.8, 1.4 Hz, 1 H, fc), 5.58 (dt, J = 2.8, 1.4 Hz, 1 H, fc), 7.06–7.23 (m, 2 H of PPh₂ and 1 H of NH), 7.35–7.52 (m, 6 H, PPh₂), 7.58–7.66 (m, 2 H, PPh₂). 31P{1H} NMR (CDCl₃): δ 5.3 (s with 195Pt satellites, 1J₁P-P = 3695 Hz). IR (Nujol): ν₁H = 3386 m, amide I 1632 vs, NH 3366 m, amide II 1533 s, 1411 w, 1303 s, 1172 w, 1101 s, 1051 w, 1036 s, 1011 w, 960 w, 881 w, 848 m, 834 m, 820 w, 756 s, 748 w, 708 s, 696 s, 626 w, 609 w, 556 m, 527 s, 496 s, 478 s, 439 m, 417 cm⁻¹. MS [ESI⁺]: m/z 776 [(M + Na⁺), 681 [(M – HCl – Cl⁻)].

Characterisation data for cis-[PtCl₂(1-k⁺S,P)] (cis-1). 1H NMR (CDCl₃): δ 2.09 (s, 3 H, SMe), 2.60 (t, 1J₁H-P = 6.7 Hz, 2 H, SCH₂), 3.44 (q, 1J₁H-P = 6.4 Hz, 2 H, HNC₃), 4.49 (virtual t, J = 1.8 Hz, 2 H, fc), 4.58 (virtual t, J = 1.7 Hz, 2 H, fc), 4.64 (virtual t, J = 1.9 Hz, 2 H, fc), 4.88 (virtual t, J = 1.9 Hz, 2 H, fc), 6.39 (t, 1J₁H-P = 5.8 Hz, 1 H, NH), 7.30–7.49 (m, 6 H, PPh₂), 7.60–7.70 (m, 4 H, PPh₂). 31P{1H} NMR (CDCl₃): δ 3.58 (s).

Reaction of [PdCl₂(cod)] with two equivalents of 1. A solution of ligand 1 (20 mg, 0.04 mmol) in chloroform (2 mL) was added to solid [PdCl₂(cod)] (6 mg, 0.02 mmol). The resulting red mixture was stirred at room temperature for 1 h and evaporated under vacuum. 1H NMR and 31P{1H} NMR spectra revealed three sets of signals due to 1 and trans-2 (both in traces) and trans-[PtCl₂(1-κ⁻P)] (trans-4; major).

Characterisation data for trans-4. 1H NMR (CDCl₃): δ 2.09 (s, 3 H, SMe), 2.60 (t, 1J₁H-P = 6.7 Hz, 2 H, SCH₂), 3.44 (q, 1J₁H-P = 6.4 Hz, 2 H, HNC₃), 4.49 (virtual t, J = 1.8 Hz, 2 H, fc), 4.58 (virtual t, J = 1.7 Hz, 2 H, fc), 4.64 (virtual t, J = 1.9 Hz, 2 H, fc), 4.88 (virtual t, J = 1.9 Hz, 2 H, fc), 6.39 (t, 1J₁H-P = 5.8 Hz, 1 H, NH), 7.30–7.49 (m, 6 H, PPh₂), 7.60–7.70 (m, 4 H, PPh₂). 31P{1H} NMR (CDCl₃): δ 3.58 (s).
t, \( J = 1.9 \) Hz, 2 H, \( \text{fc} \)), 4.89 (virtual \( t, J = 1.9 \) Hz, 2 H, \( \text{fc} \)), 6.37 (t, \( J_{\text{HH}} = 5.9 \) Hz, 1 H, NH), 7.37–7.48 (m, 6 H, PhH), 7.61–7.70 (m, 4 H, PhH). \(^{13}\text{P} {^1\text{H}}\) NMR (CDCl\(_3\)): \( \delta 10.9 \) (s with \( ^{195}\text{pt} \) satellites, \( J_{\text{PP}} = 2615 \) Hz).

**Reaction of K[PtCl\(_3\)(C\(_2\)H\(_4\))] with two equivalents of 1.** A solution of 1 (20 mg, 0.04 mmol) in chloroform (1 mL) was added to a solution of K[PtCl\(_3\)(C\(_2\)H\(_4\))] (8 mg, 0.02 mmol) in methanol (1 mL). The resulting orange-red mixture was stirred at room temperature for 90 min and evaporated. \(^1\text{H}\) NMR and \(^{31}\text{P} {^1\text{H}}\) NMR spectra again indicated the presence of \( \text{cis}-3, \) and \( \text{trans}^{-3} \) in trace amounts, and the bis(phosphate) complexes \( \text{cis}^{-3} \) and \( \text{trans}^{-3} \) in the ratio of 1 : 2 as the major products. The ratio did not change during refluxing for 18 h.

**X-Ray crystallography**

Single-crystals suitable for X-ray diffraction analysis were grown from hexane–toluene (1), hexane–chloroform (\( \text{trans}^{-2} \)-1/2H\(_2\)O, \( \text{cis}^{-3} \)) and pentane–ethyl acetate (\( \text{trans}^{-3} \)-1/2CH\(_3\)CO\(_2\)Et) by liquid-phase diffusion at room temperature. Crystals of 10 were obtained similarly from hexane–ethyl acetate at \(-18 \) °C.

The diffraction data (\( h \geq k \geq z ; \theta_{\text{max}} = 27.0 \) or 27.5°, data completeness \( \geq 99.5\% \)) were collected with an Apex 2 (Bruker) diffractometer equipped with Cryostream Cooler (Oxford Cryosystems) using graphite-monochromated Mo K\(_\alpha \) radiation (\( \lambda = 0.71073 \) Å) and were corrected for absorption by the methods incorporated in the diffractometer software.

**Notes and references**

17 Some of the signals become well resolved at 50 °C.

18 Reaction performed under milder conditions (room temperature/1 h) afforded a mixture containing cis-3 and trans-3 in an approximate 75:25 ratio, which apparently reflects kinetic inertness of Pt(ii) and the geometry of the leaving ligand. Also seen was a signal attributable to cis-5 at δp 10.15 with 1/Jp ≈ 3800 Hz, which was not detected in the reaction mixture obtained after refluxing for 3 h.

24 Steric strain resulting from trans-chelate coordination can be expected to operate in accord with trans-influence in this case.

26 The orientation of the C24–C25 bond is nearly the same in all three complexes. Compare the angles subtended by the vector of the C24–C25 bond and the Cp1 plane being 33.0(1)° in 1, 54.7(1)° in trans-2, 55.4(2)° in trans-3, and 56.3(2)° in cis-3.

27 Epa and Epc are anodic and cathodic peak potentials, respectively. Potentials determined at the scan rate 0.1 V s⁻¹ are quoted for all irreversible processes.

28 The anodic peak current (iapa) was directly proportional to the square root of the scan rate (iapa ∝ v₁/₂), which suggests the oxidation to be a standard diffusion-controlled redox transition.

30 Ferrocene itself showed practically identical response under the experiment conditions. The observed peak separations are higher than the theoretically predicted values.
(59 mV at 25 °C), presumably due to a high resistance of the analysed solution. No $iR$ drop correction was applied to the data.

32 The process is controlled by diffusion ($i_p \propto \nu^{1/2}$); the separation of the peaks in cyclic voltammogram is 80 mV at a scan rate of 0.1 V s$^{-1}$.
