Bis(piperidinedithiocarbamato)pyridinecadmium(II) as a single-source precursor for the synthesis of CdS nanoparticles and aerosol-assisted chemical vapour deposition (AACVD) of CdS thin films†

Sixberth Mlowe,^{a,b} David J. Lewis,^b M. Azad Malik,^b James Raftery,^b Egid B. Mubofu,^c Paul O'Brien^b and Neerish Revaprasadu^{*a}

The synthesis and single-crystal X-ray structure of bis(piperidinedithiocarbamato)pyridinecadmium(II), [Cd(S₂C(NC₅H₁₀)₂(NC₅H₅))₂] are reported and its use as a precursor for the synthesis of hexagonal CdS nanoparticles and CdS thin films is presented. Thermogravimetric analysis (TGA) of this complex showed clean decomposition in two steps to give CdS. Thermolysis of the complex in hexadecylamine at different temperatures in the range 190–270 °C gave CdS nanostructures including nanorods and oval shaped particles. The band gap of the as-synthesized CdS nanoparticles varied as the temperature was increased. CdS thin films with optical direct band gaps of ca. 2.4 eV were deposited by aerosol-assisted chemical vapour deposition (AACVD) in the temperature range 350 to 450 °C using the same precursor. Powder X-ray diffraction (p-XRD) patterns of CdS nanoparticles and thin films confirmed the hexagonal phase of CdS.

Introduction

Dithiocarbamates are chelating ligands which form stable complexes with all the transition elements and also the majority of main group, lanthanide and actinide elements.¹ Cadmium complexes of dithiocarbamates with alkyl groups of varying lengths have been extensively reported.^{2–8} These complexes have been used as precursors for the deposition of high quality cadmium sulfide thin films and nanoparticles. Recently our group has reported the use of heterocyclic dithiocarbamate complexes of cadmium for shape controlled CdS nanostructures.^{9–11} Four-coordinate complexes of cadmium are known to expand their coordination number by adding neutral nitrogen-containing ligands such as pyridine, bipyridine and 1,10-phenanthroline.^{12,13}

Indeed, the physical properties and single crystal X-ray structural studies on numerous cadmium and zinc complexes comprising dithiocarbamate and aromatic nitrogen-containing chelating ligands such as pyridine, 2,2'-bipyridine and 1,10-phenanthroline have been

reported.^{14–17} These five and six coordinate complexes showed increased electron density at the metal centre. Thermal properties of these adducts include increased volatility upon introduction of the Lewis base ligands containing nitrogen.¹⁸ Studies on the effect of pyridine and other nitrogen donor ligands in heterocyclic cadmium dithiocarbamate complexes on properties of CdS nanoparticles have recently been reported. Srinivasan and Thirumaran have investigated the influence of pyridine as a ligand in the precursor for the synthesis of CdS nanoparticles.¹⁹ Onwudiwe *et al.* synthesized CdS nanoparticles by thermolysis of the 2,2'-bipyridine and 1,10-phenanthroline adduct of cadmium ethyl phenyl dithiocarbamate complexes in hexadecylamine (HDA).²⁰ In both studies, the incorporation of nitrogen-donor ligands in the precursor enhances the axial growth direction of CdS nanoparticles.²¹

Various single-source precursors have been used for the preparation of CdS thin films deposition by a number of chemical vapour deposition (CVD) methods.^{22–25} O'Brien and co-workers have reported a number of dithiocarbamatocadmium(II) complexes as single source precursors for CdS thin films using low pressure metal-organic chemical vapour deposition (LP-MOCVD).^{18,26} Aerosol-assisted chemical vapour deposition (AACVD) has been used to deposit a wide range of metal chalcogenide thin films.^{27–29} Several adducts of cadmium dithiocarbamate complexes have recently been reported but without exploring their capabilities as precursors for AACVD.^{15–17} Ehsan *et al.* used bis(*N,N*-dicyclohexyldithiocarbamato)pyridinecadmium(II) to deposit greenockite CdS thin films which proved to be suitable for application in

photoelectrochemical (PEC) cells.³⁰ CdS thin films possess good electrical and optical properties, including wide band gaps (*ca.* 2.4 eV) making it an ideal material for solar cell device fabrication.³¹

Herein, we report the synthesis and single crystal X-ray structure of the pyridine adduct of bis(piperidinedithiocarbamato)cadmium(II) and we evaluate its potential as a single-source precursor for the deposition of hexagonal CdS thin films and nanoparticles.

Experimental details

Materials

Hexadecylamine (HDA) 98%, tri-*n*-octylphosphine (TOP) 90%, piperidine 99% were purchased from Sigma-Aldrich. Petroleum ether, methanol 99.5%, carbon disulfide 99.5%, sodium hydroxide 98%, cadmium chloride 99%, pyridine and acetone were purchased from Saarchem, UnivAR and Merck chemicals. Chemicals were used without further purification.

Characterization of the precursors

Microanalysis was performed on a Perkin-Elmer automated model 2400 series II CHNS/O analyzer. Infrared spectra were recorded in the range 200–4000 cm^{−1} using a Bruker FT-IR tensor 27 spectrophotometer. Thermogravimetric analysis was carried out at a 10 °C min^{−1} heating rate using a Perkin-Elmer Pyris 6 TGA up to 600 °C in a closed perforated aluminium pan under N₂ gas.

Characterisation of CdS nanoparticles

Optical absorption measurements were carried out using a Varian Cary 50 UV-visible spectrophotometer. Quartz cuvettes (1 cm path length) were used using toluene as a reference solvent. A Perkin-Elmer LS 55 spectrofluorimeter was used to measure the photoluminescence of the CdS nanoparticles. Transmission electron microscopy (TEM) was performed using a JEOL 1010 TEM, with accelerating voltage of 100 kV, Megaview III camera, and Soft Imaging Systems iTEM software. High-resolution transmission electron microscopy (HRTEM) analyses were performed using a JEOL 2010 HRTEM with an accelerating voltage of 200 kV. Powder diffraction patterns were recorded in the high angle 2θ range (20–80°) using a Bruker AXS D8 diffractometer equipped with nickel filtered Cu-K_α radiation (λ = 1.5418 Å) at 40 kV, 40 mA, room temperature. The scan speed and step sizes were 0.05° min^{−1} and 0.00657° respectively.

Characterisation of CdS thin films

A Perkin-Elmer Lambda 1050 UV/vis/NIR spectrometer was used to carry out UV-vis absorption measurements of the CdS thin films while photoluminescence properties were measured using an Edinburgh Instruments FLS920 spectrofluorimeter. Films were carbon coated using Edwards E306A coating system prior to scanning electron microscopy (SEM) and energy dispersive X-ray spectroscopy (EDXS) analyses. SEM analysis was performed using a Philips XL-30 FEG scanning electron microscope, and EDXS was carried out using a DX4 detector. Atomic force microscopy (AFM) of CdS thin films was carried out using a Bruker

Multimode 8 instrument. X-ray diffraction studies were performed on a Bruker AXS D8 diffractometer using Cu-K_α radiation. The samples were mounted flat and scanned between 2θ = 20–80°.

Single crystal X-ray diffraction data for the compounds were collected using graphite monochromated Cu-K_α radiation (λ = 1.54178 Å) on a Bruker APEX diffractometer. The structure was solved by direct methods and refined by full-matrix least squares on *F*². All non-H-atoms were refined anisotropically. Hydrogen atoms were included in calculated positions, assigned isotropic thermal parameters and allowed to ride on their parent carbon atoms. All calculations were carried out using the SHELXTL package. The crystallographic refinement parameters are detailed in the next paragraph.

X-ray experimental and structural refinement data for [Cd(S₂C(NC₅H₁₀))₂(NC₅H₅)] (Fig. 1): C₁₇H₂₅CdN₃S₄, *M* = 512.04, monoclinic, space group *P*2(1)/*c*, *a* = 8.8114(4), *b* = 9.8021(5), *c* = 24.4201(11) Å, α (°) = 90, β (°) = 95.928(2), γ (°) = 90, volume = 2097.89(17) Å³, *Z* = 4, *D* = 1.621 mg m^{−3}, *T* = 180(2) K, reflections collected = 10 171/3882, unique reflections = [*R*(int) = 0.0534], final *R* indices [*I* > 2σ(*I*)] *R*₁ = 0.0349, *wR*₂ = 0.0870, *R* indices (all data) = *R*₁ = 0.0365, *wR*₂ = 0.0882, largest diff. peak and hole = 0.830 and −0.571 e Å^{−3}, GOF = 1.048. CCDC 984434.

Synthesis of the precursors

Organic salts of sodium piperidinedithiocarbamato (ligand), bis(piperidinedithiocarbamato)cadmium(II) and its adduct, bis(piperidinedithiocarbamato)pyridinecadmium(II) were prepared by methods reported previously.^{9–11,19} A brief description of each synthesis is given below.

Preparation of ligands

Carbon disulfide (6.0 mL, 0.1 mol) was added in small portions to an equimolar solution of sodium hydroxide (4.0 g, 0.1 mol, in

Fig. 1 The X-ray single crystal structure of [Cd(S₂C(NC₅H₁₀))₂(NC₅H₅)]. Selected bond lengths (Å) and bond angles (°): Cd(1)–N(3) 2.320(2), Cd(1)–S(3) 2.5648(7), Cd(1)–S(2) 2.5758(7), Cd(1)–S(1) 2.6322(7), Cd(1)–S(4) 2.6684(7), N(3)–Cd(1)–S(3) 107.57(6), N(3)–Cd(1)–S(2) 111.32(6), S(3)–Cd(1)–S(2) 106.77(2), N(3)–Cd(1)–S(1) 102.46(6), S(3)–Cd(1)–S(1) 148.57(2), S(2)–Cd(1)–S(1) 69.65(2), N(3)–Cd(1)–S(4) 94.03(6), S(3)–Cd(1)–S(4) 69.25(2), S(2)–Cd(1)–S(4) 153.95(2), S(1)–Cd(1)–S(4) 99.90(2).

25 mL of distilled water) and piperidine (9.8 mL, 0.1 mol) cooled in an ice bath at 0 °C. After 15 min, a precipitate formed which was then air dried and recrystallized in a mixture of acetone–petroleum ether. The final product was collected, washed with chloroform and suction dried.

$\text{NaS}_2\text{C}(\text{NC}_5\text{H}_{10})$, yield: 16.4 g (90%). ^1H NMR (400 MHz, D_2O): σ 1.41 (m, 2H, 3- CH_2), 1.53 (t, 2H, 4- CH_2), 4.28 (t, 2H, 2- CH_2). Preparation of $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2]$ complex and its adduct $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$

Cadmium chloride (0.92 g, 5.0 mmol) was dissolved in distilled water (25.0 mL) and added drop-wise to the corresponding solution of the piperidinedithiocarbamate ligand (10.0 mmol, 1.832 g). The reaction mixture was stirred for 1 h, and the precipitate formed was filtered, washed with excess distilled water and dried under vacuum at 70 °C. 0.53 g (1.0 mmol) of the product was dissolved in pyridine (py, 25 mL). The light yellow solution obtained was filtered into a beaker and allowed to crystallize at room temperature. After 2 days, the colourless crystals which had formed were isolated by filtration, washed with hexane and dried.

Preparation of cadmium sulfide (CdS) nanoparticles

Cadmium sulfide nanocrystals were prepared by decomposition of $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ in hexadecylamine (HDA). In a typical reaction, HDA (6 mL) was heated to 190 °C in a three necked flask, and then purged with N_2 . 0.5 g of precursor was dispersed in 6.0 mL of TOP. The resultant solution was then injected into 6.0 g of hot HDA in a three necked flask. The temperature was maintained for one hour and the mixture was allowed to cool at room temperature. Addition of methanol (45 mL) produced a yellow precipitate which was separated by centrifugation. The yellow residue was washed twice with methanol and redispersed in toluene for further characterisation.

Aerosol assisted chemical vapour deposition of CdS thin films

CdS thin films were grown on glass substrates under an argon flow of 160 mL min^{-1} using chloroform as solvent at deposition temperatures of 350 °C, 400 °C and 450 °C. In a typical deposition, 0.2 g (0.4 mmol) of the precursor was dissolved in chloroform (10 mL) in a two-necked 100 mL round-bottom flask with a gas inlet that allowed the carrier gas (argon) to pass into the solution to aid the transport of the aerosol which had been produced using a commercially available humidifier unit.

This flask was connected to the reactor tube by a piece of reinforced tubing. The argon flow rate was controlled by a Platon flow gauge. Seven glass substrates were placed inside the reactor tube, which is then placed in a Carbolite furnace.

Results and discussion

The pyridine adduct of cadmium piperidine dithiocarbamate complex was synthesized by the reaction of excess pyridine with parent material complex. The complexes are air and moisture stable. In our previous work we synthesized CdS nanoparticles using the cadmium piperidine dithiocarbamate (DTC) and cadmium tetrahydroisoquinoline dithiocarbamate complexes as single source precursors.^{9,10} In this work we studied the effect of pyridine in the complex, on the shape of CdS nanoparticles at different reaction temperatures. Additionally, AACVD was performed to deposit CdS thin films at different temperatures.

The single crystal X-ray structure of bis(piperidinedithiocarbamato)pyridinecadmium(II) $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$, is shown in Fig. 1. There are three coordinating ligands of two different molecules in the symmetric unit of the complex. Coordination to the central Cd(II) metal is characterised by $4 \times \text{S}$ and $1 \times \text{N}$ bonds from two piperidine dithiocarbamate (bidentate) and pyridine ligands, respectively forming a five coordinated complex. The geometry of the complex is a square pyramidal. The bond lengths of Cd–S range from 2.5648 to 2.6684 Å, which are longer than that of Cd–N (2.320 Å) as expected. Two of the Cd–S bond lengths are relatively longer than the other two in each dithiocarbamate ligand as observed previously.³² Structural refinement data are given in the experimental; selected bond angles and lengths are presented in the caption to Fig. 1.

Thermogravimetric analysis (TGA) gives insight into the decomposition of precursors and what products might be expected. TGA of the pyridine adduct of bis(piperidine dithiocarbamato)cadmium(II) complex reveal a two-step decomposition with weight loss between *ca.* 130 and 320 °C (Fig. 2). The solid decomposition residue amounts to 31% for the pyridine adduct which is close to the calculated value of 28% for CdS for this complex. Previous studies on the cadmium piperidine dithiocarbamate complexes had steep one-step decomposition with a rapid weight loss at 329 °C, mirrored in the second decomposition step of the pyridine adduct.¹⁰ In the case of the adduct, the first decomposition temperature is due to the loss of the pyridine ligand, confirmed by the percentage loss of 14.1% from the TGA plot.

CdS nanoparticles were synthesis from the thermolysis of $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ in hexadecylamine at various temperatures, and their optical properties were tested. Usually, two photoluminescence (PL) emission peaks can be observed from semiconductor nanoparticles. The first is excitonic emission which is sharp and located near the absorption edge of the particle and a second deep trap emission which is broad and Stokes shifted compared to the excitonic emission.^{33,34} The UV-vis absorption

Fig. 2 Thermogravimetric analysis (TGA) plot of the pyridine adduct $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ at a heating rate of $10^\circ\text{C min}^{-1}$ under a nitrogen atmosphere.

spectrum for CdS nanoparticles synthesized at 190°C reveal a sharp absorption band edge at 468 nm (Fig. 3(A)). The corresponding PL spectrum displays a narrow band edge emission, with a maximum at 478 nm (Fig. 3(A)). The bathochromic shift observed is typical for nanostructured semiconductors.^{35,36} There is also a weaker broad emission observed in the $560\text{--}670\text{ nm}$ regions which is most likely due to electron-hole recombination from surface defects. The Stokes shift observed is typical for nanostructured semiconductors.^{35,36}

The effect of reaction temperature on the optical absorption of CdS nanoparticles has been investigated. The absorption spectra for CdS nanoparticles synthesized at 190 , 230 and 270°C are shown in Fig. 3(B). The well-defined absorption band edge at 468 nm observed for the CdS synthesized at 190°C is less prominent for the samples synthesized at 230 and 270°C . The band edge for CdS nanoparticles synthesised at 230°C is observed at 479 nm , while the band edge of CdS nanoparticles synthesised at 270°C is further red-shifted to 496 nm . Reaction time produced negligible effects in the optical spectra; samples were collected after 1 and 2 hours with little changes in the absorption and emission spectra. The formation of CdS nanocrystals was also monitored with UV-vis absorption spectroscopy. As nanoparticles grow in size, the bandgap absorption edge is bathochromically shifted. Upon increase of the reaction temperature from 190°C to 270°C , the growth rate of the CdS nanocrystals is increased. A potential reason for this phenomenon could be that higher reaction temperature results in the formation of irregular nanoparticles with reduced crystallinity due to random, faster nucleation and with the rapid growth affecting the ligand configuration at the nanocrystal surface.³⁷

TEM and HRTEM images of the CdS nanoparticles synthesised from $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ at 190 , 230 and 270°C are shown in Fig. 4(a)–(f). The CdS nanoparticles obtained at low temperature (190°C) are rod shaped (Fig. 4(a)) with a length of $64.38 \pm 4.62\text{ nm}$, a width of $5.20 \pm 0.98\text{ nm}$ and an aspect ratio of 12.38 . Similar morphologies were obtained using $[\text{Cd}(\text{S}_2\text{CNC}_5\text{H}_{10})_2]$ as a precursor whereby multiple-armed rods of CdS were obtained.^{9–11} When the reaction temperature was increased to 230°C (Fig. 4(c)), rods with a reduced average

Fig. 3 (A) UV-vis absorption (blue) and PL (red) spectra of HDA capped CdS nanoparticles at 190°C and (B) combined UV-vis absorption spectra for CdS nanoparticles synthesized at (i) 190°C , (ii) 230°C and (iii) 270°C reaction temperatures. PL spectra are corrected for instrument response.

length of $24.84 \pm 4.42\text{ nm}$ and breadth of $6.58 \pm 1.02\text{ nm}$ were obtained. The corresponding HRTEM images (Fig. 4(b) and (d)) show particles with lattice fringes. The particles synthesized at 230°C have lattice fringes with a d -spacing of 3.15 \AA corresponding to the (002) plane of hexagonal CdS. At 270°C , the shape of the CdS nanoparticles evolved from rod to an oval shaped morphology with diameters ranging from 16.8 to 23.3 nm (Fig. 4(f)); the aspect ratio of the nanorods decreased with the increase in temperature.³⁷ The oval shape of the particles was confirmed by the HRTEM image (Fig. 4(f)). The lattice fringes have a d -spacing of 3.13 \AA corresponding to the (002) basal plane of hexagonal CdS. In summary, CdS nanoparticles synthesized at higher temperature, favour the thermodynamic growth regime resulting in isotropic particles (spherical and cubes) while CdS nanoparticles synthesised at lower temperatures favour non-equilibrium kinetic growth regime and yields anisotropic particles (rods).³⁸

The powder X-ray diffraction (p-XRD) patterns of the CdS nanoparticles grown at various temperatures are shown in Fig. 5, and could all be indexed to the hexagonal phase of CdS (card number: 03-065-3414). Diffraction peaks at $2\theta = 24.80^\circ$, 26.32° ,

Fig. 4 TEM and HRTEM images of HDA capped CdS nanoparticles synthesized by thermolysis of $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ at temperatures of (a, b) 190 °C, (c, d) 230 °C and (e, f) 270 °C.

28.12° , 43.70° , 47.82° and 51.82° which correspond to the (100), (002), (101), (110), (103) and (112) planes of hexagonal CdS respectively were observed in the diffraction patterns. The high intensity and narrower (002) peak in p-XRD pattern of CdS nanoparticles indicate that the nanoparticles were elongated along the *c*-axis.²¹

CdS thin films were deposited by AACVD on glass substrates using $[\text{Cd}(\text{S}_2\text{C}(\text{NC}_5\text{H}_{10}))_2(\text{NC}_5\text{H}_5)]$ as precursor and deposition

Fig. 5 p-XRD patterns of the hexagonal CdS nanoparticles. Spectra are offset in *y* for clarity.

Fig. 6 (a) UV-vis absorption of CdS thin films deposited by AACVD at (i) 350 °C, (ii) 400 °C and (iii) 450 °C. Inset: Tauc plot showing the estimated optical band gap (2.4 ± 0.2 eV). (b) Photoluminescence emission spectra of CdS thin films at (i) 350 °C and (ii) 400 °C ($\lambda_{\text{exc}} = 350$ nm). PL spectra are corrected for instrument response.

temperatures of 350 °C, 400 °C and 450 °C. The UV-vis absorption spectra of the CdS thin films are shown in Fig. 6(a). The sharp absorption edges of the samples at *ca.* 516 nm confirm the energy of the optical band gap. The optical features of the CdS films were not significantly affected by deposition temperature, with an excitonic peak around 496 nm (2.5 eV); the band gaps estimated are commensurate with those previously reported for CdS thin films.^{39,40} The variation of the fluorescence spectrum of the CdS thin films with reaction temperature is shown in Fig. 6(b). There is one narrow and sharp emission peak in the photoluminescence (PL) spectrum due to excitonic emission for the CdS films deposited at 350 °C and 400 °C located at around 510 nm. The sharp excitonic emission peaks located near the absorption edge of the films are due to fewer surface trap states.⁴¹ CdS thin films deposited at 450 °C display a much more undefined and broader emission profile (Fig. S1, ESI†).

SEM studies show that the morphology of the CdS films change with deposition temperature. CdS films synthesized at 350 °C have regular hexagonal-like domains (Fig. 7). These structures are approximately 310 nm in size with uniform coverage on the substrate CdS films synthesized at 400 °C have a surface showing various morphological features with sizes

Fig. 7 SEM images of CdS thin films deposited at (a) 350 °C, magn. 20 000×; (b) 400 °C, magn. 2560× and (c) 450 °C, magn. 20 000×.

ranging from 200 nm to 500 nm. There is a further change of morphology for films deposited at 450 °C, where close to spherical granules are observed. The coverage is non-uniform with clustered growth predominant on the substrate. Films deposited using the parent piperidine dithiocarbamate complex at similar deposition temperatures show faceted morphology with uniform film coverage (Fig. S2, ESI†). The films obtained at 400 °C show the presence of some rod-like structures. Energy dispersive X-ray spectroscopy (EDXS) at 20 kV confirmed the stoichiometry of CdS thin films deposited at 350 °C, 400 °C and 450 °C (Table 1).

The surface topography of the as-deposited CdS films was investigated by scanning probe atomic force microscopy (AFM). Fig. 8 shows height profiles of CdS films deposited at various temperatures on glass substrates. AFM of the CdS films deposited show the presence of uniform and crack-free surface morphologies characterized by well-interconnected spherical crystallites. The typical root-mean square roughness (R_q) was 16.9 nm, 17.8 nm and 22.7 nm at deposition temperatures of (a) 350 °C, (b) 400 °C and (c) 450 °C respectively. The increase in surface roughness with increasing deposition temperature is associated with an increase in grain size. It is evident that the deposition temperature of the thin film modifies the grain sizes as well as the surface roughness. An even and regular morphology is required for respectable performance in photovoltaic devices.⁴²

The crystalline structure of the as-grown CdS thin films deposited onto glass substrates were confirmed by p-XRD using

Table 1 Elemental analysis by EDXS (atomic %) of CdS thin films at three different deposition temperatures

Temperature (°C)	Cd at%	S at%	Cd/S ratio
350	50.4	49.6	1.02
400	51.5	48.5	1.06
450	53.0	47.0	1.13

Fig. 8 2-D and 3-D AFM height profiles of CdS thin films deposited by AACVD at (a and b) 350 °C, (c and d) 400 °C and (e and f) 450 °C.

Cu K_{α} ($\lambda = 1.5406 \text{ \AA}$) radiation, with measurements in the 2θ range of 20 to 80°. The diffraction patterns of CdS thin films (Fig. 9) indicate the crystalline nature of films with the greenockite (hexagonal) structure (JCPDS card no 04-002-3090). The seven reflections at 2θ correspond to the (hkl) planes (100), (002), (101), (102), (110), (103) and (112) respectively; confirming that the product formed is pure crystalline CdS. There are no signs of any crystalline impurities such as elemental cadmium, sulfur and CdO.

Fig. 9 p-XRD pattern of greenockite CdS thin films deposited by AACVD.

Conclusions

The structure of the pyridine adduct of bis(piperidine dithiocarbamate)cadmium(II) has been elucidated and its use as a precursor for CdS nanoparticles and thin films have been established. The HDA-capped CdS nanoparticles synthesized at 190 °C shows a sharp absorption band edge, with corresponding narrow Stokes shifted photoluminescence emission. Predominantly rod-shaped morphology was observed for particles synthesized at lower reaction temperatures, whereas oval shaped particles were observed at higher reaction temperatures. CdS thin films deposited by AACVD on glass substrates at a range of temperatures consisted of faceted hexagonal-like particles at lower reaction temperatures, with clustered growth observed at higher temperatures. Both SEM and AFM confirmed the uniform surface coverage of the films. The hexagonal phase was dominant for both the nanoparticles and thin films, as evidenced by p-XRD measurements.

Acknowledgements

The authors are grateful to the National Research Foundation (NRF), Department of Science and Technology (DST) South Africa, India-Brazil-South Africa Project (IBSA) and Royal Society Leverhulme Africa Award for financial support. The authors also thank the Centre for Electron Microscopy, University of Kwa-Zulu Natal for transmission electron microscopy measurements. This work was also funded by the U.K. Engineering and Physical Sciences Research Council (Core Capability in Chemistry, EPSRC grant number EP/K039547/1). We thank Dr Louise Natrajan (University of Manchester) for access to the EI spectrofluorimeter and Dr Chris Muryn (University of Manchester) for maintaining the AFM instrument used in these studies.
