We describe an efficient synthesis of the methylene-bridged biscarbazole alkaloids bismurrayafoline-A, bismurrayafolinol and chrestifoline B-D using an Ullmann-type coupling at the benzylic position.

A wide range of carbazole alkaloids has been isolated and investigated towards their biological activity. How have less is known about the pharmaceutical potential of biscarbazoles and only a few synthetic approaches have been described. How have developed several methods for the synthesis of carbazoles. Using our palladium-catalysed construction of the carbazole framework, we recently described efficient synthetic routes to biscarbazole alkaloids, How example the oxygen-bridged biscarbazole oxydimurrayafoline and the N-aryl linked murrastifoline-A. He biscarbazole linkage was constructed by etherification, he biscarbazole linkage was constructed by etherification, herein, we report the synthesis of methylene-bridged biscarbazole alkaloids by palladium(0)- and copper(1)-catalysed coupling reactions at the benzylic position at C-3 of the carbazole framework.

The first methylene-bridged biscarbazole alkaloid obtained from natural sources was bismurrayafoline-A (1), isolated in 1983 by Furukawa *et al.* from the root bark of *Murraya euchrestifolia* Hayata (Fig. 1).¹¹ Bismurrayafoline-A (1) showed a weak activity against some cancer cell lines.¹² In 2001, Bringmann *et al.* reported the formation of bismurrayafoline-A (1) in up to 19% yield as a by-product of the reduction of mukonine (6d) (7 steps, 9% overall yield of 1).¹³ We have described a total synthesis of bismurrayafoline-A (1) *via* an unprecedented rearrangement during an Ullmann coupling (6 steps, 28% overall yield of 1).⁸ In 1987, Furukawa *et al.* isolated bismurrayafolinol (2) from the root bark of *Murraya euchrestifolia* Hayata.¹⁴ Bringmann *et al.* reported the formation of bismur-

(R = CHO)

rayafolinol (2) as a by-product in up to 6% yield (7 steps, 3% overall yield of 2) during their synthesis of murrayafoline-A (6a). Chrestifoline-D (3) was isolated in 1992 by Furukawa and Wu *et al.* from the root bark of *M. euchrestifolia*. The first synthetic approach by partial synthesis starting from bismurrayafolinol (2) was reported along with the isolation. Chrestifoline-B (4) and chrestifoline-C (5) were isolated in 1990 by Furukawa *et al.* from the same natural source. Chrestifoline-C (5) has been obtained in an optically active form ($[\alpha]_D = -5.6$, CHCl₃). but its absolute configuration is not known.

The biscarbazoles 1–5 have an identical benzylic subunit which corresponds to murrayafoline-A (6a), but they differ in the benzylic substituent (Fig. 1). For the biscarbazoles 1–3, the benzylic linkage leads to the nitrogen atom of a 1-oxygenated tricyclic carbazole corresponding to murrayafoline-A (6a), koenoline (6b) or murrayanine (6c), respectively. For chrestifo-

line-B (4) and chrestifoline-C (5), the pyrano[3,2-a]carbazole alkaloids girinimbine (7a) and mahanimbine (7b) serve as benzylic substituents. The mono-carbazole building blocks of the biscarbazoles 1-5 are found in nature as well. The 1-methoxycarbazole alkaloids, murrayafoline-A (6a), koenoline (6b), murravanine (6c) and mukonine (6d), have been obtained from diverse plants of the Rutaceae family. The pyrano[3,2-a]carbazole alkaloids girinimbine (7a) and mahanimbine (7b) were isolated first by Chakraborty et al. from Murraya koenigii Spreng. 17,18 Our group previously described synthetic routes to all individual carbazole fragments present in the biscarbazoles 1-5. An efficient iron-mediated synthesis of the 1-methoxycarbazole alkaloids 6a-d was reported early on. 7,19 More recently, an optimised palladium-catalysed synthesis of mukonine (6d) was described. Several synthetic routes to girinimbine (7a) and an efficient access to mahanimbine (7b) were also developed by our group.²⁰

For the synthesis of the biscarbazoles 1-5 we envisaged a retrosynthetic cleavage of the C-N linkage between both carbazole units which leads to the carbazoles 8 and 9 as precursors (Scheme 1). In our approach the nitrogen atom of carbazole 8 serves as a nucleophile. Thus, carbazole 8 is represented by the unprotected naturally occurring carbazoles 6a-c, 7a and **7b.** The fragment **9** should have a leaving group at the benzylic position and would be represented by an appropriate koenoline derivative. Compound 9 can be prepared from mukonine (6d) which is readily available using the arylamine 10 as the starting material.⁷

The Buchwald-Hartwig coupling of bromobenzene and arylamine 10 in the presence of SPhos followed by palladium(II)catalysed oxidative cyclisation afforded mukonine (6d) in 91% yield over both steps (Scheme 2).7 Boc-protection of 6d and subsequent reduction of the ester group led to the protected koenoline 11. Next, the hydroxy group had to be transformed into a leaving group. However, in light of the high reactivity of

the benzylic position of the koenoline derivative 11,7 the resulting compound should have sufficient stability in order to serve as the central intermediate en route to the methylenebridged biscarbazole alkaloids. Treatment of 11 with p-nitrobenzoyl chloride in the presence of stoichiometric amounts of DMAP afforded quantitatively the p-nitrobenzoate 12. In contrast to the corresponding mesylate, the *p*-nitrobenzoate **12** is much more stable towards benzyl cation formation. Thus, the koenoline derivative 12 with an activated benzylic position is available in five steps and 88% overall yield and was subsequently used as a relay compound for the synthesis of the methylene-bridged biscarbazole alkaloids 1-5.

First, we envisaged a Buchwald-Hartwig coupling reaction of the p-nitrobenzoate 12 with mukonine (6d). Only a few methods have been described so far using transition metalcatalysed coupling reactions at the benzylic position.²¹ Reaction of 12 and 6d in the presence of catalytic amounts of palladium(II) acetate, rac-BINAP and stoichiometric amounts of caesium carbonate in toluene at reflux provided the desired biscarbazole 13a in 27% yield along with the deprotected biscarbazole 13b in 35% yield (Scheme 2, Table 1). The concomitant partial removal of the Boc group could result either from a pericyclic reaction under thermal conditions²² or from a base-promoted saponification. Coupling of 12 and 6d under

Table 1 Coupling of the p-nitrobenzoate 12 with mukonine (6d)

| Reaction conditions | Products, yield (%) |
|------------------------------------------------------------------------------------------------------------------------|------------------------|
| 1.3 equiv. 6d , 10 mol% $Pd(OAc)_2$, 10 mol% rac -BINAP, 1.4 equiv. Cs_2CO_3 , toluene, reflux, 4 d. | 13a, 27%; 13b, 35% |
| 1.3 equiv. 6d , 0.2 equiv. CuBr, 0.4 equiv. pyrrole-2-carboxylic acid, 4 equiv. K_3PO_4 , DMSO, 110 °C, 40 h. | 13b , 63% |

Ullmann conditions, using substoichiometric amounts of copper(1) bromide in the presence of pyrrole-2-carboxylic acid, 23 led only to the deprotected biscarbazole 13b in 63% yield (see the Experimental procedure). Therefore, the Ullmann coupling reaction is superior for the present synthesis as it provides directly the biscarbazole 13b and thus avoids an additional deprotection step. Reduction of biscarbazole 13b with diisobutylaluminium hydride provided bismurrayafolinol (2) in 96% yield. The spectroscopic data of 2 are in full agreement with those reported for the natural product.§ Reduction of 13b using lithium aluminium hydride afforded bismurrayafolinol (2) in 90% yield but did not lead to bismurrayafoline-A (1). Apparently, N-substituted carbazoles do not form the quinone imine methide intermediate required for the complete reduction to a 3-methylcarbazole, 5i,13,24 and thus, further reduction of the 3-(hydroxymethyl)carbazole does not occur. Oxidation of bismurrayafolinol (2) with manganese(IV) oxide^{25,26} led to chrestifoline-D (3).§

Using the Ullmann-type coupling of the *p*-nitrobenzoate 12 with the appropriate carbazole building blocks **6a**, **7a** and **7b**,

Scheme 3 Synthesis of bismurrayafoline-A (1), chrestifoline-B (4), and chrestifoline-C (5). Reagents and conditions: (a) 1.5 equiv. 6a, 0.4 equiv. CuBr, 0.8 equiv. pyrrole-2-carboxylic acid, 4 equiv. K_3PO_4 , DMSO, 110 °C, 2 d, 46%; (b) 1.5 equiv. 7a, 0.2 equiv. CuBr, 0.4 equiv. pyrrole-2-carboxylic acid, 4 equiv. K_3PO_4 , DMSO, 125 °C, 40 h, 41%; (c) 1.5 equiv. 7b, 0.2 equiv. CuBr, 0.4 equiv. pyrrole-2-carboxylic acid, 4 equiv. K_3PO_4 , DMSO, 120 °C, 40 h, 32%.

the methylene-bridged biscarbazoles 1, 4 and 5 became directly available (Scheme 3).

Thus, reaction of murrayafoline-A (6a)⁸ with the *p*-nitrobenzoate 12 provided bismurrayafoline-A (1) in 46% yield.§ The Ullmann-type coupling of the nitrobenzoate 12 with girinimbine (7a)^{20c} afforded chrestifoline-B (4) and the reaction of 12 with mahanimbine (7b)^{20c} provided (±)-chrestifoline-C (5).§ A comparison of the four Ullmann-type couplings described herein reveals that mukonine (6d), which obviously is more stable under the reaction conditions, provided the best yield (63%) for the copper-induced C-N bond formation with compound 12.

In conclusion, five naturally occurring methylene-bridged biscarbazole alkaloids were synthesised using an Ullmann-type coupling at the benzylic carbon atom of the relay compound 12 as the key reaction. Using the present route, the biscarbazole alkaloids 1–5 become available *via* short and efficient synthetic routes, bismurrayafoline-A (1): 6 steps, 41% overall yield; bismurrayafolinol (2): 7 steps, 53% overall yield; chrestifoline-D (3): 8 steps, 42% overall yield; chrestifoline-B (4): 6 steps, 36% overall yield; and (±)-chrestifoline-C (5): 6 steps, 28% overall yield based on the arylamine 10. Chrestifoline-B (4) and (±)-chrestifoline-C (5) have been obtained by total synthesis for the first time. Studies concerning the bioactivity of the biscarbazole alkaloids 1–5 are in progress.

Experimental procedure

Experimental procedure for the Ullmann-type coupling to the biscarbazole 13b:

A solution of the p-nitrobenzoate 12 (66.6 mg, 0.140 mmol), freshly dried potassium phosphate (120 mg, 0.566 mmol), mukonine (6d) (46.4 mg, 0.182 mmol), copper(1) bromide (4.0 mg, 28 µmol), and pyrrole-2-carboxylic acid (6.2 mg, 56 μmol) in DMSO (1 mL) was heated at 110 °C for 40 h. Water (1.5 mL) and a saturated aqueous solution of ammonium chloride (3 mL) were added, the layers were separated and the aqueous layer was extracted three times with ethyl acetate. The combined organic layers were dried over magnesium sulfate and the solvents were removed under reduced pressure. Purification of the residue by flash chromatography on silica gel (gradient elution with petroleum ether-ethyl acetate, 19:1 to 7:3) afforded the biscarbazole 13b (40.9 mg, 63%) as a colourless solid; mp 152.5–153 °C.
