# Quinoidal diindenothienoacenes: synthesis and properties of new functional organic materials†‡

Gabriel E. Rudebusch, Aaron G. Fix, Hillary A. Henthorn, Chris L. Vonnegut, Lev N. Zakharov and Michael M. Haley\*

We report the preparation and characterization of a new class of quinoidal thienoacenes. The synthetic route is efficient, high-yielding and scalable with the potential for further functionalization. Single crystal X-ray diffraction reveals that, as size increases, the molecules pack in progressively closer 1D arrangements. The title compounds are shown to have amphoteric redox behaviour by cyclic voltammetry. The anion radicals are studied by EPR spectrometry and by computations. The electron-accepting nature, NIR absorption and the low-lying LUMO energies (ca.  $-4.0$  eV) allude to potential use in materials applications.

## Introduction

Quinoidal oligothiophenes (QOTs) and quinoidal thienoacenes (QTAs) have attracted significant interest as functional organic materials (Fig. 1). Initially, the preparation of thiophene oligomers and study of their reduced and oxidized forms provided models for the doped portions of polythiophene.<sup>1</sup> One of the first small molecules to exhibit ambipolar character in an OFET was based on a terthienuquinoidal core (1).<sup>2</sup> Thorough

understanding of the stability of the reduced and oxidized states of 1 led to increased OFET performance and the discovery of ambipolar transport characteristics.<sup>3</sup> Otsubo, Aso and coworkers accomplished the synthesis of the largest family of QOTs (2).<sup>4</sup> Solubility issues of the larger QOTs were solved by fusion of a solubilizing bis(butoxymethyl)cyclopentane unit to the thiophene core. The longest members ( $n = 5, 6$ ) featured open-shell ground states and low-energy absorptions to 1400 nm.<sup>5</sup> A terthiophene derivative of 2 as the active layer in OFETs was also described.<sup>6</sup> Recently, Zhu *et al.* reported n-channel behaviour in thin films of QTA 3.<sup>7</sup> As noted by the authors, isomerization issues inherent in QOTs are eliminated by moving to the fused QTA core. Lastly, the QTA scaffolds are promising for nonlinear optics due to their rigidity and symmetry.<sup>8</sup> Large alternant polycyclic hydrocarbons possessing low energy triplet excited states and multiphoton absorption properties are of interest for singlet exciton fission.<sup>9</sup>

Our group has initiated studies on a seldom explored class of quinoidal molecules based on the indenofluorene skeleton.<sup>10</sup> While most of our work has focused on indeno[1,2-*b*]fluorenes,<sup>11</sup> we have reported derivatives of indeno[2,1-*c*]fluorene 4<sup>12</sup> and fluoreno[4,3-*c*]fluorene 5 (Fig. 2),<sup>13</sup> which exhibit interesting absorption profiles and amphoteric redox behaviour. Very recently we reported the fully conjugated indacenedithiophenes,<sup>14</sup> where thiophenes replaced the outer benzene rings of indeno[1,2-*b*]fluorenes. In analogy, exchange of the bridging  $sp^2$  carbon units in 4 and 5 with isoelectronic sulfur atoms to provide 6 and 7 is an attractive and straightforward approach to further tune the quinoidal core of indenofluorenes. Sulfur incorporation into the framework of polycyclic hydrocarbons is a versatile method to promote good solid-state ordering and improve stability at ambient conditions.<sup>15</sup>

Herein we describe the synthesis and characterization of a series of quinoidal diindeno(thi)thiophenes (DI[*n*]Ts)

Fig. 3 Structures of diindenothiophenes (DI[n]Ts).

(Fig. 3). This work represents a new approach to quinoidal thienoacenes through the fusion of electron-accepting indene fragments to a thienoacene core. The ease of thiophene synthesis and anticipated stability of the final quinoidal molecules are appealing features of this strategy. Possible substituents include (trialkylsilyl)ethynyl groups to favour solid-state order<sup>16</sup> and aryl groups to tune the electronics<sup>11b,c</sup> of the architecture.

## Results and discussion

Synthesis is initiated by Suzuki–Miyaura cross-coupling of 3,4-dibromothiophene and commercially available 2-ethoxy-carbonylbenzeneboronic acid (Scheme 1). Use of Buchwald's SPhos ligand was critical for efficient coupling of the electron-rich bromothiophene with the electron-poor arylboronic acid.<sup>17</sup> Next, saponification of diester **8** followed by formation of the acid chloride and Friedel–Crafts acylation provides dione **9** in good yield. Gratifyingly, we found that 3,4-dibromothiophene could be mono-acylated to give **10** in 92% yield. Condensation

with ethyl thioglycolate in the presence of potassium carbonate furnishes thienothiophene **11** in 80% yield. This route avoids the preparation of unsubstituted thieno[3,2-*b*]thiophene either through traditional methods<sup>18</sup> or the improved Matzger route.<sup>19</sup> Suzuki–Miyaura cross-coupling gives diester **12** in quantitative yield. Elaboration to **13** proceeds in 79% yield over four steps.

Dione **15** was prepared in an analogous manner *via* diester **14** starting from 3,5-dibromodithieno[3,2-*b*:2',3'-*d*]thiophene. Notably, the synthesis of diones **9**, **13** and **15** can be performed on multi-gram scale with no silica gel chromatography (see ESI† for full details). Nucleophilic addition of (trialkylsilyl)ethynyl lithium proceeds quantitatively despite poor solubility of the dione starting materials. Reduction of the respective diols by anhydrous SnCl<sub>2</sub> in toluene gives the quinoidal DI[n]Ts in modest to very good yield. Interestingly, the reduction to **DI3T** is complete within minutes while the reduction to **DI1T** and **DI2T** requires several hours to reach full conversion. The final compounds were stable toward silica gel and ambient conditions. No measures to protect the compounds from air or water were taken and no significant decomposition was observed in solution or in the solid-state.

Single crystals of DI[n]Ts sufficient for characterization by X-ray diffraction were obtained by slow evaporation from CH<sub>2</sub>Cl<sub>2</sub>. **DI1T-TIPSE** arranges into a pairwise slipped stacks with distances between average planes of 3.30 Å within the pair and 3.37 Å between adjacent pairs (Fig. 4, left). Lateral (short-axis) slip of the core was found to be 1.06 Å in the pair and 5.82 Å between pairs. **DI1T-TESE** also packs in pairwise slipped stacks with the distance between average planes of the molecules of 3.43 Å in the pair and 3.34 Å between pairs (Fig. 4, right). The smaller trialkylsilyl group altered the lateral slip to 2.52 Å in the pair and 2.55 Å between pairs. **DI2T** forms an alternating 1D structure rather than the dimers seen with **DI1T** due to its centrosymmetry (Fig. 5, top). The distance between the average planes is 3.41 Å with a lateral slip of 1.46 Å between cores of the molecules. Spacing between neighbouring 1D stacks was greater than van der Waals distance. **DI3T** shows strong overlapping of the quinoidal cores with inter-planar distance of 3.46 Å and lateral slip of 1.79 Å and 1.23 Å (Fig. 5, bottom). The 1D columns are essentially insulated from adjacent columns by the (triisopropylsilyl)ethynyl groups.

Table 1 summarizes the bond distances in the core of the DI[n]T family.<sup>20</sup> All three show distinct bond alternation with the double bonds averaging 1.36–1.37 Å and single bonds 1.44–1.45 Å, fully supporting the proposed quinoidal structures. These values are also in good agreement with those observed in their purely hydrocarbon analogues.<sup>12,13</sup> The peripheral benzene rings in the DI[n]Ts have an average bond distance of 1.390 Å with a standard deviation of 0.006 Å. The molecules are essentially planar, as the root-mean-square (RMS) deviation from the average molecular plane is negligible; **DI1T-TIPSE** showed the greatest RMS deviation of only 0.042 Å.<sup>21</sup>

In addition to the DI[n]Ts, we were able to obtain single crystals suitable for X-ray diffraction of diones **9** and **13** from CHCl<sub>3</sub>/cyclohexane and upon slow cooling from refluxing nitrobenzene, respectively (Fig. 6).<sup>22</sup> Dione **9** alternates its orientation within the 1D stack such that the molecular

**Scheme 1** Synthesis of **DI1T**, **DI2T** and **DI3T**; reagent and conditions: (a) 2-ethoxycarbonylbenzeneboronic acid, Pd<sub>2</sub>dba<sub>3</sub>, SPhos, K<sub>3</sub>PO<sub>4</sub>, toluene, 100 °C; (b) (i) KOH, EtOH, reflux; (ii) oxalyl chloride, DMF, CH<sub>2</sub>Cl<sub>2</sub>, rt; (iii) AlCl<sub>3</sub>, CH<sub>2</sub>Cl<sub>2</sub>, 0 °C to rt; (c) (i) (trialkylsilyl)ethynyllithium, 0 °C, then sat. NH<sub>4</sub>Cl; (ii) SnCl<sub>2</sub>, toluene, rt; (d) benzoyl chloride, AlCl<sub>3</sub>, 0 °C to rt; (e) ethyl thioglycolate, K<sub>2</sub>CO<sub>3</sub>, DMF, 60 °C. TIPSE = (triisopropylsilyl)ethynyl, TESE = (triethylsilyl)ethynyl.

**Fig. 4** Solid-state packing of **DI1T-TIPSE** (left) and **DI1T-TESE** (right).

arrangement would result in a net dipole; however, the dipole of the neighbouring stack balances the opposing dipole (see Fig. S4†). Dione **13** shows a more ordered 1D arrangement due to its centrosymmetry. The distance between the average planes of **9** and **13** are essentially identical at 3.39 Å and 3.38 Å, respectively. Dione **9** has a significant RMS deviation from planarity of 0.079 Å while **13** is nearly planar at 0.027 Å. This is likely due to the steric crowding of the hydrogens in the bay region of **9**. Interestingly, the carbonyl oxygens of **9** and **13** show a strong interaction with the bay carbons of adjacent stacks with distances of 3.25 Å for **9** and 3.28 Å for **13**.

The deeply colored DI[*n*]Ts were characterized further by absorption spectroscopy (Fig. 7). All compounds exhibit strong, acene-like vibronic features from 350–600 nm and low energy absorptions reaching into the NIR (800–925 nm). The absorption edges are staggered, possibly as a result of the family's alternating axo-/centro-symmetry. Interestingly, **DI1T** and **DI2T** exhibit similar absorbance profiles to the related indeno[2,1-*c*]-

**Fig. 5** Solid-state packing of **DI2T** (top) and **DI3T** (bottom).

fluorene and fluoreno[4,3-*c*]fluorene derivatives (Fig. S1†). For the DI[*n*]Ts, the high energy bands red shift by *ca.* 50–70 nm and the low energy bands blue shift by *ca.* 25–35 nm. Analogues to **4** and **5**, the DI[*n*]Ts are non-emissive.

DI[*n*]Ts exhibit two reversible one electron reductions in solution as examined by cyclic voltammetry (Fig. 8 and Table 2). **DI1T** shows a reversible oxidation while the oxidation of **DI2T**

and **DI3T** are essentially irreversible. The difference between  $E_{\text{red}}^1$  and  $E_{\text{red}}^2$  decreases by *ca.* 0.1 V upon sequential expansion of the quinoidal core. This is most likely due to the mitigation of Coulombic repulsion in the doubly reduced species.<sup>24</sup> The values for  $E_{\text{ox}}$  appear to approach a constant, indicating that incorporation of additional thiophene units does not alter the ionization potential to a large degree. LUMO and HOMO energy levels were derived from the  $E_{\text{red}}^1$  and  $E_{\text{ox}}$  values, respectively.  $E_{\text{gap}}$  decreases over the series in nonlinear fashion.

The DI[n]T anion radicals were obtained by reduction of the neutral species with K metal in THF. The EPR spectrum of

<sup>a</sup> Values reported as the half-wave potential (*vs.* SCE) using the  $\text{Fc}/\text{Fc}^+$  couple (0.46 V) as an internal standard. HOMO and LUMO energy levels in eV were approximated using  $\text{SCE} = -4.68$  eV *vs.* vacuum (see ref. 23) and  $E_{1/2}$  values for reversible processes or  $E_p$  values for irreversible processes;  $E_{\text{gap}} = \text{LUMO} - \text{HOMO}$ . Calculated energy levels (B3LYP/6-31G(d,p)) in parentheses.

a blue solution of **DI1T**<sup>•-</sup> is shown in Fig. 9; see ESI for the EPR spectra of **DI2T**<sup>•-</sup> (Fig. S8<sup>†</sup>) and **DI3T**<sup>•-</sup> (Fig. S9<sup>†</sup>). The hyperfine coupling constants (HFCCs) of the spin active nuclei were determined and experimental carbon spin densities ( $\rho_c$ ) were calculated by the McConnell equation (Tables 3 and S1<sup>†</sup>). Due to the lack of spin active nuclei on the core of DI[n]T,  $\rho_c$  could not be directly calculated. Very little spin density is contained within the fused benzene rings

Fig. 9 EPR spectrum of the radical anion of DI1T.

Table 3 Carbon spin densities ( $\rho_c$ )<sup>a</sup>

Position	DI1T	DI2T	DI3T

B	0.012	0.016	0.014
C	0.044	0.029	0.028
D	0.004	0.010	0.010
E	0.112	0.103	0.094
Remainder	0.59	0.64	0.66

<sup>a</sup> See ESI for full details; labeling scheme on right.

(0.004–0.044), with more contained in the ethynyl group (0.094–0.112). The approximate spin densities remaining in the core for DI1T, DI2T, and DI3T are 0.59, 0.64, and 0.66, respectively, indicating that a majority of the spin density resides in the thienoacene unit.

DFT calculations were performed to predict the geometry of the neutral, radical anion and dianion states of the DI[*n*]Ts. For computational ease, trimethylsilyl was used in place of the larger TIPS/TES groups. Bond distances in the core of DI2T are shown in Fig. 10 and Table S3;† see ESI for calculated geometries of DI1T (Fig. S10 and Table S2†) and DI3T (Fig. S12 and Table S4†). The calculations replicate the quinoidal character of the neutral DI[*n*]Ts but overestimate the degree of bond alternation in DI2T and DI3T by as much as 0.02 Å compared to the solid state data (Table 1). Upon one electron reduction, the quinoidal bonds begin to homogenize as the unpaired electron is delocalized over the system. The dianion shows a reversal of the quinoidal pattern and thus the expected rearomatization of the central thiophenes.<sup>25</sup> In accord with the CV experiments, the dianionic, fully aromatic species is stabilized with respect to the neutral state.

Fig. 10 DFT calculated DI2T bond distances upon reduction (R = (trimethylsilyl)ethynyl); performed at UCAM-B3LYP/6-31G(d,p) (neutral) and UCAM-B3LYP/6-31++G(d,p) (radical anion/dianion) level of theory.

## Conclusions

In summary, the synthesis and characterization of a new class of quinoidal thienoacenes has been reported. The synthetic route is shown to be rapid and amenable to scale. X-ray crystallography corroborates the presence of distinct quinoidal motifs and reveals that the title compounds pack in progressively closer pairwise 1D arrangements. Analysis of the reduced states by EPR spectra and DFT calculations indicate stable anionic species. The large degree of  $\pi$ -orbital overlap, NIR absorption and favourable electrochemical properties suggest great potential for application in organic electronics. Future work will consist of further derivatization and expansion of the DI[*n*]T structures as well as testing their performance as organic semiconductors.

## Acknowledgements

We thank the National Science Foundation (CHE-1301485) for support of this research as well as support in the form of instrumentation (CHE-0840478 and CHE-0923589) and computer grants (OCI-0960354). We also thank Dr Brad Rose for guidance on the EPR and computational studies and Prof. Mark Lonergan (University of Oregon) for use of his group's potentiostat. HRMS were obtained at the Mass Spectrometry Facilities and Services Core of the Environmental Health Sciences Center, Oregon State University, supported by grant #P30-ES00210, National Institute of Environmental Health Sciences, National Institutes of Health.
