Asymmetric hydroamination catalyzed by a new chiral zirconium system: reaction scope and mechanism†

Xiaoguang Zhou,^{ab} Bing Wei,^{ab} Xiu-Li Sun,^a Yong Tang^{*a} and Zuowei Xie^{*bc}

A new class of chiral zirconium complexes supported by chiral tridentate [O⁻NO⁻]-type of ligands derived from amino acids were synthesized and structurally characterized. They catalyzed asymmetric hydroamination/cyclization of primary aminoalkenes to give five- and six-membered N-heterocyclic amines with up to 94% ee.

Hydroamination as a highly atom-economic reaction for efficient synthesis of nitrogen containing compounds has received great attention. In particular, chiral intramolecular hydroamination provides a convenient way to obtain chiral N-heterocycles, which plays an important role in pharmaceuticals.¹ Since the first report on asymmetric hydroamination in 1992 based on chiral ansa-lanthanocenes,² several chiral catalyst systems have been developed, including group 4 metals,³ alkaline earth metals,⁴ alkali metals,⁵ late transition metals,⁶ rare earth metals^{2,7–12} and chiral Brønsted acids.¹³ Though significant progress has been made in the past decade in this field, the reported enantioselective systems remain very limited. In view of the recent progress in asymmetric catalysis,¹⁴ it is envisioned that new ligand design, new catalyst synthesis, and mechanism tests may offer strategies for addressing challenging issues in asymmetric olefin hydroamination, thus further advancing this field.

Very recently, we reported a highly active cationic zirconium system based on a tridentate [O⁻N⁻S] ligand for catalytic hydroamination with a broad substrate scope from primary amines to secondary amines, and from terminal alkenes to much less reactive internal alkenes.¹⁵ This system also catalyzed tandem intramolecular hydroamination of primary aminoalkenes to give bicyclic amines, and was tolerant of many functional groups.

We wondered if chiral ligands derived from such a tridentate backbone system would offer both high catalytic activity and enantioselectivity in asymmetric hydroamination. Here we report the new chiral catalyst systems for asymmetric hydroamination of aminoalkenes with up to 94% ee and ≥95% conversion. The reaction mechanism is also discussed.

Initially, a series of new chiral auxiliary [O⁻N⁻O] ligands were synthesized *via* the condensation of salicylaldehyde with *O*-alkylated chiral aminoalcohol, followed by reduction with LiAlH₄ (see ESI†). They were treated with 1 equiv. of tetrabenzyl-zirconium in toluene to give new chiral dibenzyl zirconium complexes **1–4** (Chart 1). Screening results on catalytic hydroamination of 2,2-diphenyl-4-pentenamine (**6A**) indicated that **4b** offered the best ee value and the lability of the OR² group disfavored the chiral induction (Table S3 in ESI†). To fix this problem, a covalent bond between the Zr atom and O(2) was desirable, which led to the design of a new ligand backbone. Subsequently, a series of new ligands with a [O⁻NO⁻] backbone were prepared. Their Zr complexes **5a–f** were also synthesized and characterized by various spectroscopic data and single-crystal X-ray analyses (Fig. S8–S11 in ESI†). Scheme 1 shows the screening results of **5a–f**. The enantioselectivity of the reaction was greatly improved, 74% ee for **5a**, 89% ee for **5b** and 68% ee for **5c**. It was clear that *gem*-disubstituents had a large impact on ee values with *gem*-dimethyl being the best choice. Replacement of a five-membered N-heterocycle by a six-membered one (**5e**) or a fused five-membered ring (**5f**) offered similar enantioselectivity. After identifying **5b** as the best catalyst for hydroamination of **6A**, the effect of reaction temperature on enantioselectivity was examined and the results are listed in Table S4 (ESI†).

Under the optimal reaction conditions, several substrates were examined, and the results are summarized in Table 1. Both five- and six-membered N-heterocyclic ring products were generated with up

to 94% ee. The substrate **6B** gave spiro[4,5] product **7B** in 93% ee (entry 2), and the substrate **6C** offered spiro[4,4] product **7C** in 87% ee (entry 3). Desymmetrization with the two allyl groups in aminodiene **6F** produced both diastereomers with 88% ee and 92% ee, respectively, whereas the diastereoselectivity was low (1 : 1.7) (entry 6). Upon replacing phenyl in **6F** with methyl, even higher ee values of 90% and 93% were achieved (entry 5). The *gem*-dialkyl effect was also observed. As anticipated, replacement of *gem*-diphenyl substituents in **6A** by *gem*-dimethyl-ones resulted in a much lower activity (entry 4). Complex **5e** was found to give **7G** in 66% ee, which represents the best enantioselectivity so far observed for the hydroamination of **6G** (entry 7).

Since **5b** did not show catalytic activity toward secondary aminoalkenes, it seemed that the above [ONO]Zr(CH₂Ph)₂ system might proceed *via* a Zr-imido intermediate. Many attempts to isolate the

Scheme 2 Reaction of **8** with *t*-BuNH₂.

reaction intermediate from the stoichiometric reaction of **5b** with **6A** were unsuccessful. We then prepared an achiral Zr complex **8** with the same [O⁻NO⁻] backbone. It could catalyze the hydroamination of **6A** to a racemic mixture of **7A** with a comparable activity to **5b**.

Reaction of **8** with an excess amount of *t*-BuNH₂ in toluene at room temperature gave an imido-bridged zirconium amide complex **9** in 44% yield. Complex **9** also catalyzed the hydroamination of **6A** to offer (±)**7A** in a similar activity to that of **8**. Single-crystal X-ray analyses reveal that **9** is a dimer with bridging imido ^tBuN and alkoxy units, respectively (Scheme 2). One of the Zr atoms is five coordinated, and the other is six coordinated. In addition, each Zr atom is σ-bonded to one amido unit ^tBuNH, and the two ^tBuNH moieties are oriented in *trans* positions (Fig. S13 in ESI[†]).

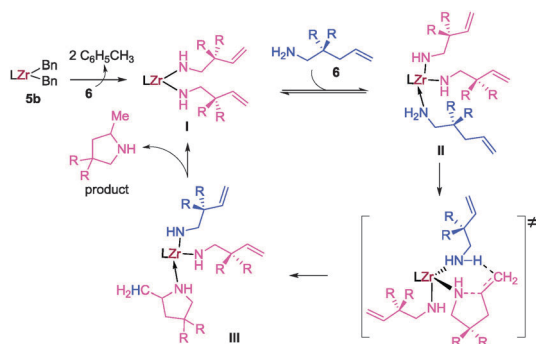

To gain further insight into the reaction mechanism, a kinetic analysis of hydroamination/cyclization of aminoalkene **6A** catalyzed by **5b** was performed for the determination of an empirical rate law using *in situ* ¹H NMR monitoring. Ferrocene was employed as an internal ¹H NMR integration standard, as it was readily differentiated from the substrate, product, and catalyst resonances in deuterated toluene. The appearance of the product **7A** CH₂CH signal was monitored as a function of time and normalized *versus* the internal standard.¹⁶

The results show that there is a first-order dependence on both catalyst and substrate concentration, giving the empirical rate law in the following equation on the basis of initial rate measurements: rate = *k*_{obs}[catalyst][substrate].

To gauge the effect of *N*-deuteration on the reaction catalyzed by **5b**, the conversion of *d*₂-**6A** was studied (Scheme 3). It was found that the cyclization of *N*-deuterated *d*₂-**6A** was much slower than for the proteo counterpart **6A**, giving *k*_H/*k*_D = 5.2 at 60 °C (see Fig. S19 in ESI[†]).

To further probe the nature of the turnover-limiting step, the temperature dependence of the cyclization rate of **6A** was investigated by determining the *k*_{obs} values at 50 °C, 60 °C, 70 °C and 80 °C (see Fig. S20 in ESI[†]). The Eyring plot generated from these data is shown in Fig. S21 in ESI[†]. The calculated thermodynamic parameters are Δ*H*[‡] = 9.9 ± 0.3 kcal mol⁻¹ and Δ*S*[‡] = -53.4 ± 0.9 cal K⁻¹ mol⁻¹, which are very comparable to Δ*H*[‡] = 6.7 ± 0.2 kcal mol⁻¹ and Δ*S*[‡] = -43 ± 7 cal K⁻¹ mol⁻¹ observed for the [PhB(C₆H₄)(OX)]Zr(NMe₂)₂ system.^{3f} These values may also be compared to Δ*H*[‡] = 17 to 21 kcal mol⁻¹ and Δ*S*[‡] = -13 to -23 cal K⁻¹ mol⁻¹ in the salicyloxazoline zirconium system¹⁷ and Δ*H*[‡] = 20.1 ± 0.5 kcal mol⁻¹ and Δ*S*[‡] = -21 ± 1 cal K⁻¹ mol⁻¹ in

Scheme 3 Primary kinetic isotopic effect observed in the cyclization of **6A** (E = H/D).

Scheme 4 Proposed catalytic cycle for intramolecular hydroamination.

the tethered bis(ureate)zirconium system.¹⁸ The parameters obtained in the current study show a highly organized transition state.

Though **9** displayed a similar catalytic activity to that of **8** and **5b**, it was not clear whether a dinuclear species was involved in the turnover-limiting step of the catalytic cycle as the first-order dependence on precatalyst concentration was observed. Accordingly, experiments on the non-linear effect were carried out. A strict linear relationship between the ee values of **7A** and those of precatalyst **5b** was observed (see Fig. S22 in the ESI[†]), as would be expected for the exclusively monomeric mechanism. In addition, the ¹H NMR spectrum showed that **9** dissociated into the monomeric form [ONO]Zr(NHBU)₂ in the presence of excess *t*-BuNH₂ (see Schemes S1 and S2 in ESI[†]). These results suggest that the reaction may proceed *via* a mononuclear intermediate.

In addition, the isotopic substitution significantly affects the reaction's enantioselectivity, where the % ee's for deuteropyrrolidines are systematically and significantly higher than the values for the corresponding proteo-pyrrolidines (see Table S7 in ESI[†]). Such effects show that an N–H (or N–D) bond is involved in the stereochemistry-determining step, supporting a concerted C–H/C–N bond forming mechanism.^{3d}

On the basis of aforementioned experimental data, a plausible catalytic mechanism is proposed in Scheme 4. Initial aminolysis of the precatalyst **5b** by excess substrates liberates toluene to give a monomeric species **I**. The third substrate binds reversibly to the Zr atom to give the species **II**. Intramolecular hydroamination takes place *via* irreversible C–H and C–N bond formation through a highly ordered transition state. This is supported by a very large and negative value of ΔS^\ddagger ($-53.4(9)$ cal K⁻¹ mol⁻¹) as well as a large KIE value of 5.2. The dissociation of neutral pyrrolidine regenerates the active catalyst **1** to complete the catalytic cycle. Such a mechanism is similar to those reported in the literature.^{3d,18}

In summary, this work describes our journey of exploring new chiral zirconium catalysts for asymmetric hydroamination/cyclization. Through systematic studies, we have developed a class of new pincer-like [O⁻NO⁻]Zr systems that can efficiently catalyze the hydroamination of primary aminoalkenes with up to 94% ee and $\geq 95\%$ conversion. The catalyst structure–enantioselectivity relationships have also been addressed, which may shed some light on the ligand design of new catalyst systems. A mechanism has also been proposed to account for all of the experimental observations, which involves a highly ordered transition state and a concerted bond formation pathway.
