# Mechanism of a one-photon two-electron process in photocatalytic hydrogen evolution from ascorbic acid with a cobalt chlorin complex†

Shoko Aoi,<sup>a</sup> Kentaro Mase,<sup>a</sup> Kei Ohkubo<sup>ab</sup> and Shunichi Fukuzumi<sup>\*abc</sup>

**A one-photon two-electron process was made possible in photocatalytic H<sub>2</sub> evolution from ascorbic acid with a cobalt(II) chlorin complex [Co<sup>II</sup>(Ch)] via electron transfer from ascorbate to the excited state of [Ru(bpy)<sub>3</sub>]<sup>2+</sup> followed by electron transfer from [Ru(bpy)<sub>3</sub>]<sup>+</sup> to Co<sup>II</sup>(Ch) with proton to give the hydride complex, which reacts with proton to produce H<sub>2</sub>. [Co<sup>III</sup>(Ch)]<sup>+</sup> was reduced by ascorbate to reproduce Co<sup>II</sup>(Ch).**

Photocatalytic production of hydrogen (H<sub>2</sub>) has attracted increasing attention as a clean energy source because of the ever-increasing demand for energy and climate change on our planet.<sup>1</sup> A number of highly efficient hydrogen evolving systems have been developed including homogeneous and heterogeneous photocatalytic systems.<sup>2–13</sup> Two electrons are required to produce H<sub>2</sub> from protons, although one photon generates normally only one electron. A mechanism of photocatalytic production of H<sub>2</sub> was reported to clarify how photoinduced electron transfer of a photosensitizer (a one-electron process) leads to H<sub>2</sub> production (a two-electron process).<sup>14–16</sup> Disproportionation of one-electron reduced species of metal complexes resulted in formation of the two-electron reduced species from which H<sub>2</sub> is formed.<sup>17</sup> Bimolecular reactions of metal(III)–hydride complexes also generate H<sub>2</sub> accompanied by regeneration of metal(II) complexes.<sup>18</sup> In each case, the maximum quantum yield of H<sub>2</sub> production per photon is 50%, because two photons are required to produce two electrons. Thus there has so far been no example for one photon to generate one H<sub>2</sub> molecule.

We report herein photocatalytic H<sub>2</sub> evolution from ascorbic acid (AscH<sub>2</sub>) with a cobalt(II) chlorin complex [Co<sup>II</sup>(Ch)] (a chemical structure shown in Scheme 1)<sup>19</sup> in an aqueous acetonitrile solution (H<sub>2</sub>O/MeCN), which proceeds *via* a one-photon two-electron process. The photocatalytic mechanism is clarified by nano-second laser transient absorption spectra and by examining each step in the catalytic cycle independently.

Visible light irradiation of a deaerated (Ar-saturated) H<sub>2</sub>O/MeCN solution (1 : 1 v/v) of [Ru(bpy)<sub>3</sub>]<sup>2+</sup> (bpy = 2,2'-bipyridine) containing ascorbic acid (AscH<sub>2</sub>) and ascorbate (AscH<sup>−</sup>) (*E*<sub>ox</sub> = 0.43 V vs. SCE) as an electron donor and Co<sup>II</sup>(Ch) (*E*<sub>red</sub> = −0.96 V vs. SCE) (Fig. S1 in the ESI†) as a catalyst resulted in H<sub>2</sub> evolution (Fig. 1, black line). When the ratio of AscH<sup>−</sup> to AscH<sub>2</sub> was changed as fixed total concentrations of AscH<sub>2</sub> and AscH<sup>−</sup> ([AscH<sub>2</sub>] + [AscH<sup>−</sup>] = 1.1 M), the largest H<sub>2</sub> evolution activity was attained with AscH<sup>−</sup> (0.30 M) and AscH<sub>2</sub> (0.80 M) (Fig. S2 in ESI†). The smaller concentration of AscH<sup>−</sup> results in less efficient reductive quenching of the [Ru(bpy)<sub>3</sub>]<sup>2+</sup>\* emission (\* denotes the excited state).

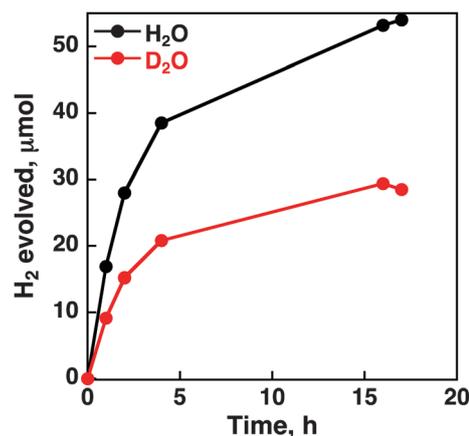

Fig. 1 Time courses of H<sub>2</sub> evolution in the photocatalytic reduction of proton in an Ar-saturated H<sub>2</sub>O/MeCN (black) and D<sub>2</sub>O/MeCN (red) mixed solution (1 : 1 v/v) containing [Ru<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup> (2.0 mM), AscH<sub>2</sub> (0.80 M), AscHNa (0.30 M) and Co<sup>II</sup>(Ch) (25 μM) under irradiation of visible light (λ > 420 nm) at 298 K.

† Electronic supplementary information (ESI) available: Experimental details and cyclic voltammograms (Fig. S1), time courses of H<sub>2</sub> evolution (Fig. S2), emission spectra (Fig. S3 and S5), UV-vis absorption spectra (Fig. S4 and S7) and kinetic data (Fig. S6–S11). See DOI: 10.1039/c5cc05064b

The quenching efficiency of  $[\text{Ru}(\text{bpy})_3]^{2+*}$  ( $E_{\text{red}} = 0.77 \text{ V vs. SCE}$  in MeCN)<sup>20</sup> by  $\text{AsCH}^-$  (0.30 M) with  $\text{AsCH}_2$  (0.80 M) was determined to be 95% (Fig. S3 in ESI†). On the other hand, the smaller concentration of  $\text{AsCH}_2$  may retard  $\text{H}_2$  production due to decreasing the acidity. When  $\text{H}_2\text{O}$  was replaced by  $\text{D}_2\text{O}$ ,  $\text{D}_2$  and HD were produced without formation of  $\text{H}_2$ . Thus, hydrogen was produced from water and ascorbic acid as electron and proton sources. The observed deuterium kinetic isotope effect (KIE) in Fig. 1 ( $k_{\text{H}}/k_{\text{D}} = 1.8$  in the initial stage) suggests that the Co–H bond cleavage of a cobalt hydride intermediate ( $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})]$ ) by proton may be the rate-determining step for the photocatalytic  $\text{H}_2$  evolution (*vide infra*).

The concentration of  $\text{Co}^{\text{II}}(\text{Ch})$  was optimised to be 50  $\mu\text{M}$  for the efficient photocatalytic  $\text{H}_2$  evolution. The absorption of  $[\text{Ru}(\text{bpy})_3]^{2+}$  is blocked by the larger concentration of  $\text{Co}^{\text{II}}(\text{Ch})$  (Fig. S4 in ESI†).<sup>21</sup> The quantum yield of the photocatalytic  $\text{H}_2$  evolution was determined to be 12% using a ferric oxalate actinometer (see the Experimental section in ESI†). This value is similar to the highest value reported for photocatalytic  $\text{H}_2$  evolution using a cobalt terpyridine complex ( $\Phi = 0.13$ ).<sup>22</sup>

Nanosecond transient absorption spectra of an  $\text{H}_2\text{O}/\text{MeCN}$  solution of  $[\text{Ru}(\text{bpy})_3]^{2+}$  with  $\text{AsCH}_2$  and  $\text{AsCH}^-$  are shown in Fig. 2, where appearance of the absorption band at 500 nm due to  $[\text{Ru}(\text{bpy})_3]^{2+*}$  is observed upon the nanosecond laser excitation. Thus, electron transfer from  $\text{AsCH}^-$  to  $[\text{Ru}(\text{bpy})_3]^{2+*}$  occurred to produce  $\text{AsCH}^\bullet$  and  $[\text{Ru}(\text{bpy})_3]^{2+}$ . The rate constant of electron transfer from  $\text{AsCH}^-$  to  $[\text{Ru}(\text{bpy})_3]^{2+*}$  ( $k_{\text{et}}$ ) was determined to be  $8.0 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$  from a slope of Stern–Volmer plot ( $K_{\text{SV}} = 3.5 \times 10^2 \text{ M}^{-1}$ ) and the lifetime of  $[\text{Ru}(\text{bpy})_3]^{2+*}$  (0.44  $\mu\text{s}$  in water/MeCN 1:1 v/v) (Fig. S5 in ESI†).<sup>23</sup> The decay rate of absorbance at 500 nm due to  $[\text{Ru}(\text{bpy})_3]^{2+*}$  obeyed the second-order kinetics of bimolecular back electron transfer from  $[\text{Ru}(\text{bpy})_3]^{2+}$  to  $\text{AsCH}^\bullet$ . In the presence of  $\text{Co}^{\text{II}}(\text{Ch})$ , the decay of absorbance became much faster because of electron transfer from  $[\text{Ru}(\text{bpy})_3]^{2+*}$  to  $\text{Co}^{\text{II}}(\text{Ch})$  as shown in Fig. 2b. The decay rate constant linearly increased with increasing the concentration of  $[\text{Co}^{\text{II}}(\text{Ch})]$  (Fig. S6 in ESI†). The rate constant of electron transfer from  $[\text{Ru}(\text{bpy})_3]^{2+*}$  to  $\text{Co}^{\text{II}}(\text{Ch})$  was determined to be  $2.5 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$  from the slope of dependence of the first-order decay rate constant on concentration of  $\text{Co}^{\text{II}}(\text{Ch})$  (Fig. S6b in ESI†).

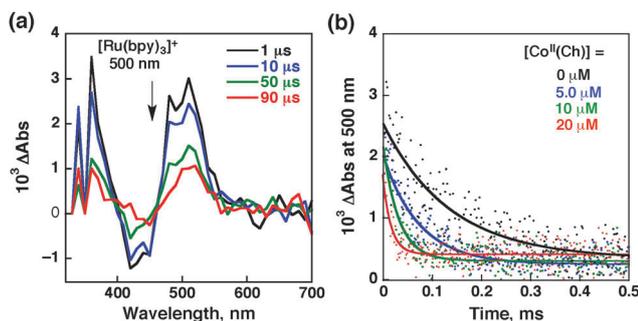

Fig. 2 (a) Transient absorption spectra after laser excitation ( $\lambda = 450 \text{ nm}$ ) of  $[\text{Ru}(\text{bpy})_3]^{2+}$  (80  $\mu\text{M}$ ) in the presence of  $\text{AsCH}_2$  (0.80 M) and  $\text{AsCHNa}$  (0.30 M) in a deaerated  $\text{H}_2\text{O}/\text{MeCN}$  mixed solution (1:1 v/v) at 298 K. (b) Time profiles of absorbance at 500 nm due to decay of  $[\text{Ru}(\text{bpy})_3]^{2+}$  in the presence of various concentrations of  $\text{Co}^{\text{II}}(\text{Ch})$  (0–20  $\mu\text{M}$ ) in deaerated  $\text{H}_2\text{O}/\text{MeCN}$  mixed solutions (1:1 v/v) containing  $[\text{Ru}(\text{bpy})_3]^{2+}$  (80  $\mu\text{M}$ ),  $\text{AsCH}_2$  (0.80 M),  $\text{AsCHNa}$  (0.30 M).

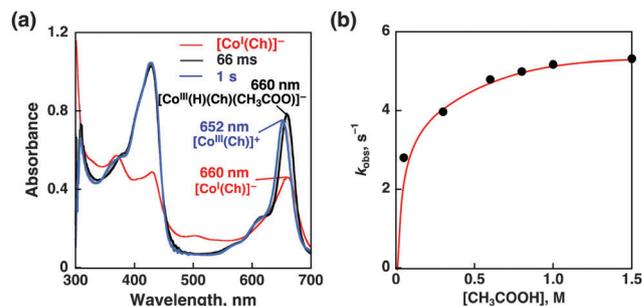

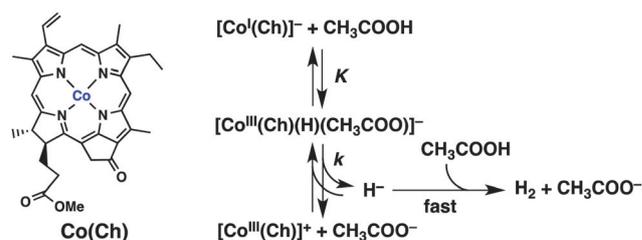

Fig. 3 (a) UV-vis absorption spectral changes of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  (30  $\mu\text{M}$ ) upon addition of  $\text{CH}_3\text{COOH}$  (0.30 M) in deaerated MeCN at 298 K. The black and blue lines show the spectra taken at 66 ms and 1 s after mixing, respectively. The red line shows UV-vis absorption spectrum of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  (15  $\mu\text{M}$ ) formed by the electron-transfer reduction of  $\text{Co}^{\text{II}}(\text{Ch})$  (15  $\mu\text{M}$ ) with  $\text{CoCp}_2^*$  (300  $\mu\text{M}$ ) in deaerated MeCN at 298 K. (b) Plot of  $k_{\text{obs}}$  for the rate of formation of  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  vs.  $[\text{CH}_3\text{COOH}]$ .

To examine the reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  that is produced by electron transfer from  $[\text{Ru}(\text{bpy})_3]^{2+}$  to  $\text{Co}^{\text{II}}(\text{Ch})$ ,  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  was prepared by the one-electron reduction of  $\text{Co}^{\text{II}}(\text{Ch})$  by decamethylcobaltocene  $[\text{Co}(\text{Cp}^*)_2]$  in MeCN (Fig. S7 in ESI†). The UV-vis absorption band of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  (red line in Fig. 3a;  $\lambda_{\text{max}} = 510 \text{ nm}$ ) decreased with increasing absorption band at 660 nm (black line) at 66 ms after addition of acetic acid ( $\text{CH}_3\text{COOH}$ ) (0.30 M). Then, this absorption band was finally blue shifted to  $\lambda_{\text{max}} = 652 \text{ nm}$ , which is due to  $[\text{Co}^{\text{III}}(\text{Ch})]^+$ .<sup>24,25</sup> Thus,  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  may react with  $\text{CH}_3\text{COOH}$  to form the hydride complex ( $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})]^-$ ;  $\lambda_{\text{max}} = 660 \text{ nm}$ ), from which  $\text{H}_2$  was evolved by the reaction with  $\text{CH}_3\text{COOH}$  to produce  $[\text{Co}^{\text{III}}(\text{Ch})]^+$ . The reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  with  $\text{CH}_3\text{COOH}$  was monitored by the absorption change at 652 nm due to  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  as shown in Fig. 3, where the rate of the formation of  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  obeyed first-order kinetics (Fig. S8 in ESI†). The first-order rate constant increased with increasing concentration of  $\text{CH}_3\text{COOH}$  to approach a constant value (Fig. 3b). Such a saturation behaviour indicates that  $\text{CH}_3\text{COOH}$  is not involved in the rate-determining step and that the reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  with  $\text{CH}_3\text{COOH}$  proceeds *via* formation of the hydride complex ( $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})]^-$ ), followed by the rate-determining heterolytic cleavage of the  $\text{Co}^{\text{III}}\text{–H}$  bond. The subsequent reaction of the released hydride ion with  $\text{CH}_3\text{COOH}$  to produce  $\text{H}_2$  and  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  may be as fast as compared with the back reaction of the  $\text{Co}^{\text{III}}\text{–H}$  bond cleavage (Scheme 1). The kinetic equation for the formation of  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  is given by eqn (1),

Scheme 1 Mechanism of hydrogen formation by the reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  with  $\text{CH}_3\text{COOH}$ .

$$d[[\text{Co}^{\text{III}}(\text{Ch})]^+]/dt = k[[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-] \quad (1)$$

where  $k$  is the rate constant of the hydrogen evolution. From the equilibrium constant ( $K$ ), the concentration of a complex between  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  and  $\text{CH}_3\text{COOH}$  is given by eqn (2), where

$$[[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-] = K[\text{CH}_3\text{COOH}][[\text{Co}^{\text{I}}(\text{Ch})]^-]_0 - [[\text{Co}^{\text{III}}(\text{Ch})]^+]/(1 + K[\text{CH}_3\text{COOH}]) \quad (2)$$

$[[\text{Co}^{\text{I}}(\text{Ch})]^-]_0$  is the initial concentration. Eqn (1) is rewritten by eqn (3).

$$d[[\text{Co}^{\text{III}}(\text{Ch})]^+]/dt = kK[\text{CH}_3\text{COOH}][[\text{Co}^{\text{I}}(\text{Ch})]^-]_0 - [[\text{Co}^{\text{III}}(\text{Ch})]^+]/(1 + K[\text{CH}_3\text{COOH}]) \quad (3)$$

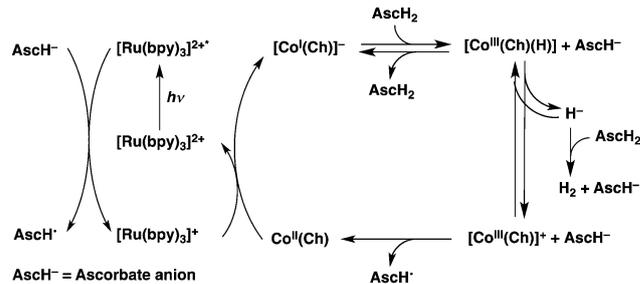

Under the conditions, the concentration of  $\text{CH}_3\text{COOH}$  is much higher than that of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$ , the  $k_{\text{obs}}$  value is given by eqn (4). To determine the  $k$  value, eqn (4) is rewritten by eqn (5), which predicts

$$k_{\text{obs}} = kK[\text{CH}_3\text{COOH}]/(1 + K[\text{CH}_3\text{COOH}]) \quad (4)$$

$$k_{\text{obs}}^{-1} = 1/kK \cdot [\text{CH}_3\text{COOH}]^{-1} + 1/k \quad (5)$$

a linear correlation between  $k_{\text{obs}}^{-1}$  and  $[\text{CH}_3\text{COOH}]^{-1}$  (Fig. S9 in ESI†). The  $k$  and  $K$  values were determined from the intercept and slope of the linear plot of  $k_{\text{obs}}^{-1}$  vs.  $[\text{CH}_3\text{COOH}]^{-1}$  to be  $5.9 \text{ s}^{-1}$  and  $7.1 \text{ M}^{-1}$ .

When  $\text{CH}_3\text{COOH}$  was replaced by  $\text{CH}_3\text{COOD}$ , the deuterium kinetic isotope effect (KIE) was observed (Fig. S10 in ESI†),<sup>26</sup> indicating that the cleavage of the Co–H bond of  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-]$  or O–H bond of  $\text{CH}_3\text{COOH}$  is involved in the rate-determining step of the reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  with  $\text{CH}_3\text{COOH}$ . Because  $\text{CH}_3\text{COOH}$  is not involved in the rate-determining step (*vide infra*), the cleavage of the Co–H bond of  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-]$  is the rate-determining step of the reaction of  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  with  $\text{CH}_3\text{COOH}$ . The KIE value was 1.7 which is virtually the same as observed for the photocatalytic  $\text{H}_2$  evolution (KIE = 1.8, Fig. 1), indicating that the heterolytic Co–H bond cleavage of  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-]$  is also the rate-determining step in the photocatalytic  $\text{H}_2$  evolution.

Scheme 2 Mechanism of photocatalytic hydrogen evolution from  $\text{AscH}^-$  and  $\text{AscH}_2$  with  $[\text{Ru}(\text{bpy})_3]^{2+}$  and  $\text{Co}^{\text{I}}(\text{Ch})$ .

$[\text{Co}^{\text{III}}(\text{Ch})]^+$  produced by the reaction of  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{CH}_3\text{COO})^-]$  with  $\text{CH}_3\text{COOH}$  is reduced by  $\text{AscH}^-$  to form  $\text{Co}^{\text{I}}(\text{Ch})$  as shown by stopped-flow measurements in Fig. 4.<sup>27</sup> The rate constant of electron transfer from  $\text{AscH}^-$  to  $[\text{Co}^{\text{III}}(\text{Ch})]^+$  that was prepared by the one-electron oxidation of  $\text{Co}^{\text{I}}(\text{Ch})$  with  $(p\text{-BrC}_6\text{H}_4)_3\text{N}^+\text{SbCl}_6^-$  in  $\text{H}_2\text{O}/\text{MeCN}$  was determined to be  $1.5 \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$  from the linear dependence of the first-order rate constant on concentration of  $\text{AscH}^-$  (Fig. S11 in ESI†).

The photocatalytic cycle is summarized in Scheme 2. Photoexcitation of  $[\text{Ru}(\text{bpy})_3]^{2+}$  resulted in electron transfer from  $\text{AscH}^-$  to  $[\text{Ru}(\text{bpy})_3]^{2+*}$  to produce  $[\text{Ru}(\text{bpy})_3]^+$ , followed by electron transfer from  $[\text{Ru}(\text{bpy})_3]^+$  to  $\text{Co}^{\text{I}}(\text{Ch})$  to produce  $[\text{Co}^{\text{I}}(\text{Ch})]^-$ , which reacts with  $\text{AscH}_2$  to produce  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{AscH})^-]$ . Hydrogen is generated by the reaction of  $[\text{Co}^{\text{III}}(\text{H})(\text{Ch})(\text{AscH})^-]$  with  $\text{AscH}_2$  via the Co–H bond heterolysis to produce  $[\text{Co}^{\text{III}}(\text{Ch})]^+$ ,<sup>28,29</sup> which is reduced by  $\text{AscH}^-$  to regenerate  $\text{Co}^{\text{I}}(\text{Ch})$ . In such a case, a one-photon two-electron process is made possible, because one photon is required to produce  $[\text{Co}^{\text{I}}(\text{Ch})]^-$  for  $\text{H}_2$  evolution and another electron is provided thermally by  $\text{AscH}^-$ .

In conclusion,  $\text{Co}^{\text{I}}(\text{Ch})$  acts as an efficient catalyst for photocatalytic  $\text{H}_2$  evolution from ascorbic acid with  $[\text{Ru}(\text{bpy})_3]^{2+}$  as a photocatalyst to attain the high quantum yield via a one-photon two-electron process in which the second electron is provided thermally from ascorbic acid.

This work was supported by Grants-in-Aid (no. 26620154 and 26288037 to K.O.) and JSPS fellowship (No. 25-727 to K.M.) from the Ministry of Education, Culture, Sports, Science and Technology (MEXT); ALCA and SENTAN projects from JST, Japan (to S.F.).
