## COMMUNICATION

Andreas Lemmerer *et al.*

Co-crystals and molecular salts of carboxylic acid/pyridine complexes:  
can calculated  $pK_a$ 's predict proton transfer? A case study of nine complexes

A series of nine complexes and 109 literature examples containing a carboxylic acid functional group and a pyridine functional group on separate molecules follow the  $\Delta pK_a$  rule such that proton transfer occurs at values above 3 to form a molecular salt and none at values below 0 to form a co-crystal. In the intermediate range, there is a predominance of molecular salt over co-crystal formation. The complexes discussed show that calculated  $pK_a$ 's are good predictors of the outcome.

Crystal engineering is about the control of the assembly of organic and inorganic components to a desired structure or a desired property.<sup>1</sup> Organic components can be used either in their unimolecular state<sup>2</sup> or in their bimolecular state with a predictable combination of different molecules.<sup>3</sup> Complexes between two or more organic compounds that remain neutral result in a multi-component molecular complex.<sup>4</sup> This scenario is often referred to as a co-crystal (or cocrystal!).<sup>5</sup> In a binary situation, an additional scenario is for the two components to undergo an intermolecular proton transfer, with complimentary acid and basic functional groups.<sup>6</sup> Such complexes are known as molecular salts<sup>5</sup> as they do not contain inorganic acids or bases. The interactions between the neutral and ionised species are often governed by a variety of intermolecular interactions,<sup>7</sup> and their strength can be dependent on the covalent or electrostatic component. In summary, hydrogen bonding interactions as seen in co-crystals have longer intermolecular distances compared to hydrogen bonds seen in molecular salts.<sup>8</sup> The key for the crystal engineer, who

## Co-crystals and molecular salts of carboxylic acid/pyridine complexes: can calculated $pK_a$ 's predict proton transfer? A case study of nine complexes†

Andreas Lemmerer,\* Stefan Govindraju, Marcelle Johnston, Xolani Motloung and Kelsey L. Savig

wants to be able to predict and hence control the assembly of his multi-component complex, is to know if in solution proton transfer will or will not take place. This depends on the basicity and acidity of the functional groups that will partake in the hydrogen bonding.<sup>9</sup> An easy route of obtaining a qualitative answer comes from looking at the difference in  $pK_a$  values of the acid and basic functional groups. There exists a “rule of 3” that states that for values of  $\Delta pK_a = pK_a$  (protonated base) –  $pK_a$  (acid) less than 0 a co-crystal forms (all components in their neutral states), and for differences greater than 3, a molecular salt forms (all components are charged, but the overall complex is neutral of course).<sup>10</sup> For an intermediate value, no accurate prediction can be made on the outcome.<sup>11</sup> These calculations are often based solely on calculated  $pK_a$ 's given for species in water solutions. In this report, we want to put these predictions to the test by preparing a series of nine complexes that have a range of calculated  $\Delta pK_a$ 's from less than 0 to greater than 3 and then observing the outcome in their solid state form. The choice of molecules was dependent on the type of functional groups, which need to be able to display hydrogen bonding both in their neutral and charged forms. Hence, molecules with a pyridine group and a carboxylic acid group on the second molecule have been chosen. The hydrogen bonds expected for a co-crystal and a molecular salt are  $\text{COO}-\text{H}\cdots\text{N}_{\text{pyr}}$  and  $\text{COO}^-\cdots\text{H}-\text{N}_{\text{pyr}}^+$ , respectively. An additional reason was that these functional groups are often found in drug molecules, and a current avenue of research in solid-state organic chemistry is the design of complexes that have neutral or charged components, as this can influence the bio-availability and solubility of the drug component.<sup>12</sup>

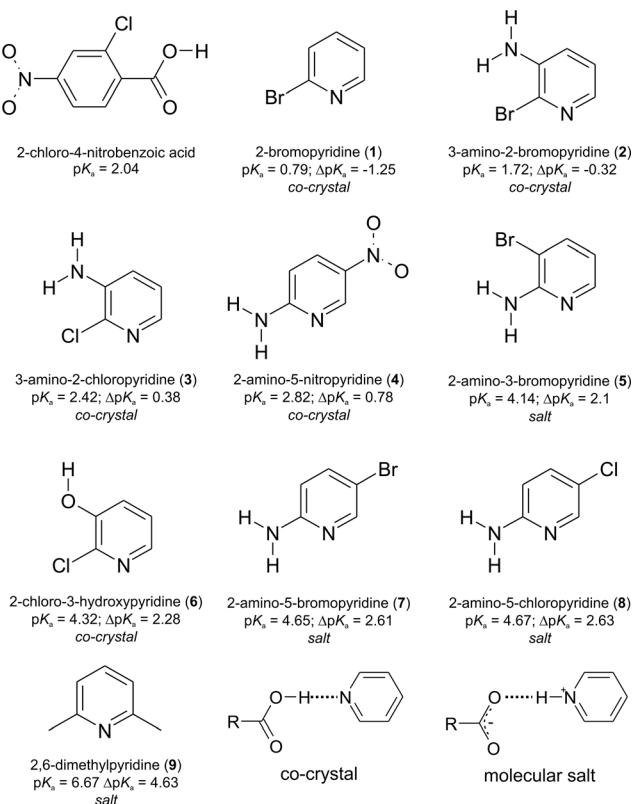

To simplify the study, the same molecule with the carboxylic acid group is used, and the second molecule contains the pyridine having a number of different substituents to form a series of nine related molecules with amine, bromo, chloro, nitro, and phenol groups. These substituents influence the basicity of the pyridine group, as shown in Scheme 1. The molecule with the carboxylic acid group is 2-chloro-4-nitrobenzoic

**Scheme 1** The structural diagrams of the carboxylic acid and nine pyridines used in this study, as well as the primary hydrogen bonding motif expected for co-crystal and salt formation. The  $pK_a$  values and resulting  $\Delta pK_a$ 's are given for all the complexes based on calculated values.

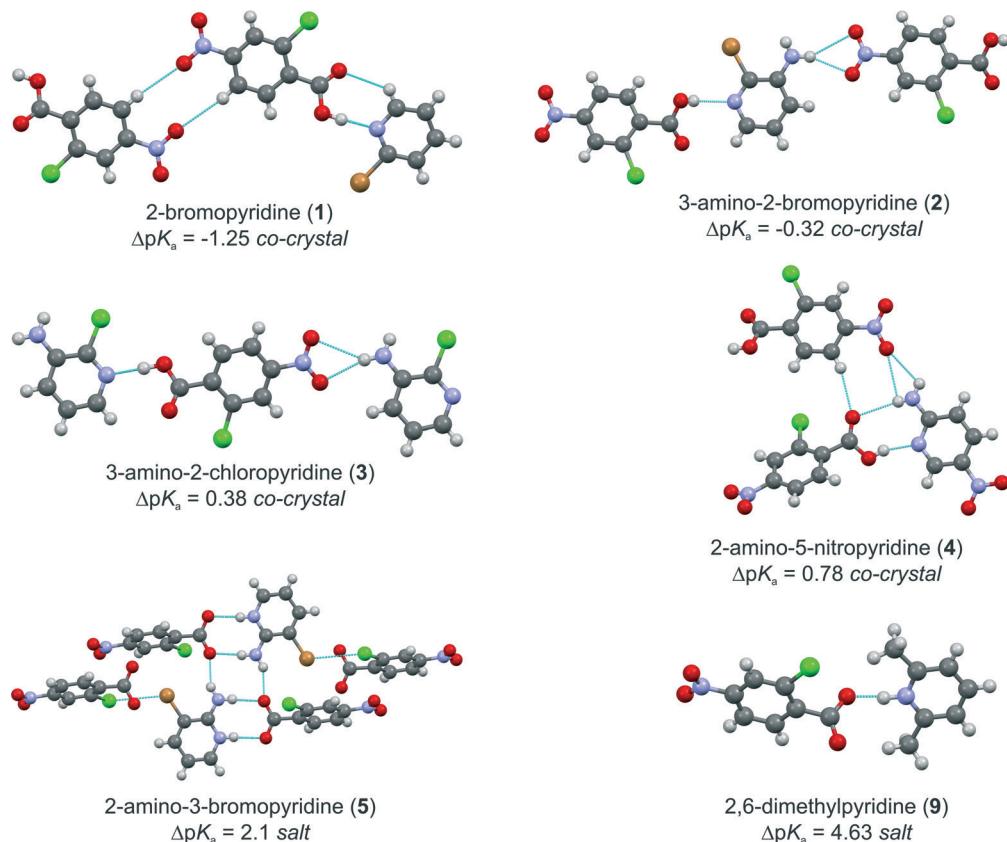

acid, which is also a potential anti-HIV molecule that has been used in crystal engineering studies before.<sup>13</sup> The  $pK_a$  values were calculated using the predictor functionality in Sci-Finder, using the programme *Advanced Chemistry Development*.<sup>14</sup> The calculation of  $pK_a$  values for drug discovery and formulation has been used by various researchers<sup>15a,b</sup> as well as in a similar study to that presented here for a matrix of 4-substituted benzoic acids and 4-substituted pyridines.<sup>15c</sup> Nine complexes (1–9) are formed. Experimentally, the same crystallization procedure was used, where a stoichiometric 1:1 ratio was used and dissolved in methanol.<sup>‡</sup> Single crystal diffraction data for all compounds was done at -100 °C.<sup>‡</sup> To put the results of the series of complexes into context, a database analysis of 109 complexes having these two functional groups was undertaken.<sup>‡</sup>

The nine different pyridines used have a range of  $pK_a$ 's from 0.79 to 6.67. The carboxylic acid used has a  $pK_a$  of 2.04. Hence, we have been able to synthesize complexes that have a  $\Delta pK_a < 0$  (co-crystals 1 and 2),  $0 < \Delta pK_a < 3$  (co-crystals 3, 4, and 6; salts 5, 7, and 8), and lastly  $\Delta pK_a > 3$  (salt 9). This is summarized in Scheme 1. The intermediate values too between 0 and 3 do indeed show that either a salt or a co-crystal can form. The most commonly seen hydrogen bonding motifs are shown in Fig. 1 and have been observed in previous work with hydroxybenzoic acids and aminopyridines.<sup>16</sup> The heterosynthon<sup>17</sup>  $\text{COO}-\text{H}\cdots\text{N}_{\text{pyr}}^+$  formed between a carboxylic

acid donor and a pyridine acceptor is observed in all the co-crystals 1–4 and 6. In 3 and 6, there is an  $\text{R}_1^2(6)$  ring formed between one of the amine H and phenol H, respectively. In the molecular salt structures, proton transfer has occurred to the pyridinium base to form a  $\text{COO}^-\cdots\text{H}-\text{N}_{\text{pyr}}^+$  hydrogen bond. In addition, a hydrogen bond from the *ortho* amine to the carboxylate group forms an 8-membered  $\text{R}_2^2(8)$  ring<sup>18</sup> motif, where the two carboxylate O atoms act as hydrogen bond acceptors and two hydrogen atoms (pyridinium-H and amine-H) as donors. In addition, an eight membered  $\text{R}_4^2(8)$  motif is observed that joins two  $\text{R}_2^2(8)$  motifs together. This pattern is seen in 5, 7 and 8. A possible reason for this commonality is the amine group *ortho* to the pyridinium group in those three structures, enabling the formation of a robust 2-aminopyridinium-carboxylate heterosynthon.<sup>19</sup> The molecular salt with 2,6-dimethylpyridine is the only one in the series that is predicted to form a salt, and that is observed. The hydrogen bonding here is simply a  $\text{COO}^-\cdots\text{H}-\text{N}_{\text{pyr}}^+$  hydrogen bond. There are no other hydrogen bonding functional groups present. There are of course further intermolecular interactions, but these are not included in the description for the sake of brevity. By looking at the average  $D\cdots A$  distances, there is a greater range for the salt compounds 5, 7–9 of 2.64(8) Å than for the co-crystal ones at 2.67(4) Å. The shortest  $D\cdots A$  distance is found in 9 (2.58(2) Å) with the greatest  $\Delta pK_a = 4.63$ . There are no other trends identifiable with regard to hydrogen bonding and  $\Delta pK_a$ , and there was no intermediate  $\text{COO}-\text{H}\cdots\text{N}_{\text{pyr}}^+/\text{COO}^-\cdots\text{H}-\text{N}_{\text{pyr}}^+$  hydrogen bonding observed. All compounds were characterized by powder X-ray diffraction and confirm bulk purity.

The database analysis of similar complexes was undertaken to identify first all the structures that have a carboxylic acid group and a pyridine, respectively, on separate molecules. Additionally, no solvated complexes were taken into consideration. A total of 109 complexes were ultimately selected and categorized as either a co-crystal or a salt. From calculated  $\Delta pK_a$ 's, predictions were made according to the  $\Delta pK_a$  rule on what type of complex should be observed and then compared to the observed result. The analysed data in a spreadsheet are given in the ESI.† Fig. 2 shows the results of the calculated  $\Delta pK_a$  and the observed complex formed. In the upper range  $\Delta pK_a > 3$  onwards, there are 38 molecular salts and no co-crystals. The range with  $\Delta pK_a < 0$  shows 22 co-crystals and no molecular salts, again as expected. In the intermediate range between 0 and 3, there are 15 co-crystals and 34 molecular salts. In fact, there are the same number of co-crystals with  $0 < \Delta pK_a < 1.5$  as there are in  $1.5 < \Delta pK_a < 3$ . The unpredictability can be seen especially when one looks at what complex is formed close to the end points of the intermediate range (in a range of 0.5): there are three co-crystals and two salts within  $0.07 < \Delta pK_a < 0.47$  and two co-crystals and three salts within  $2.52 < \Delta pK_a < 2.93$ . Hence, there is no trend of having significantly more co-crystals closer to zero and more salts closer to 3. It must also be noted that the molecular environment and the number and types of species in solution can alter the outcome.<sup>20</sup>

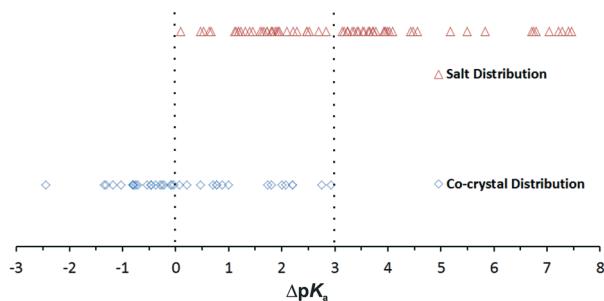

**Fig. 1** A selection of the most commonly observed hydrogen bonding interactions in complexes **1–5** and **9** together with the starting material pyridine used.

Similar studies where a range of complexes was made using pyridine derivatives as acceptors have been done (Table 1). Bhogala *et al.* looked at di- and tricarboxylic acids together with 4,4'-bipyridines and isonicotianimide.<sup>21</sup> The  $pK_a$  values were from known literature values, and the authors found that the  $pK_a$  range can be extended from 3 to 3.75. Stilinović *et al.*<sup>22</sup> studied co-crystals and salts of gentisic acid ( $pK_a = 2.82$ ) with 20 different pyridines (spanning a range of  $-0.7 < \Delta pK_a < 4.7$ ) and obtained 22 complexes. Their  $pK_a$  values were determined experimentally in aqueous solution, and their crystallizations were done using an ethanol–water solution. They found that proton transfer did not occur for  $\Delta pK_a$ 's  $< 2$  and always occurred for  $\Delta pK_a > 2.5$ . Hence, the range of uncertainty is 0.5 unit and could be indicative of the

larger range required to make accurate predictions from *calculated* instead of *experimentally* determined  $pK_a$  values. Another study was by Childs *et al.*<sup>23</sup> looking at 2-amino-pyrimidine complexes with a variety of carboxylic acids. The  $pK_a$ 's in their study were calculated using the same program as in our study. The authors found that in the range  $0 < \Delta pK_a < 2$ , eight co-crystals and seven salts were formed. It was found that the intermediate range, where either co-crystal or salt can form, should be delineated by a transition range, and not fixed values like 0 or 3. The authors account for the unpredictability of the intermediate range not only on a poor correlation between  $pK_a$  values and proton transfer but also the molecular environment, similarly to how a  $pK_a$  value can change with a change in solvent.<sup>24</sup> By also using theophylline in their study, which is amphoprotic, complexes using a series of carboxylic acids and amines showed that the ranges of  $\Delta pK_a$  can be specific for the system under investigation.

The most related work that also clearly illustrates the complexity of co-crystal *versus* salt observations according to the  $\Delta pK_a$  rule is a study by Mohamed *et al.*<sup>25</sup> that used a matrix of pyridine and 4-dimethylpyridine with 5 carboxylic acids. The  $pK_a$  values were obtained from the literature in aqueous solutions and corrected for activity effects. The complexes with pyridine formed both co-crystals and salts and the neutral  $\text{COO}-\text{H}\cdots\text{N}_{\text{pyr}}$  or ionic  $\text{COO}^-\cdots\text{H}-\text{N}_{\text{pyr}}^+$  variants of hydrogen bonds are observed, and for 4-dimethylpyridine, only salts were formed. This is in exact agreement with the  $\Delta pK_a$

**Fig. 2** The 109 complexes found in the CSD, plotted as a function of  $\Delta pK_a$  and the observed co-crystal or salt complex.

**Table 1** Studies of other carboxylic acid–pyridine complexes

Acid/pyridine	pK <sub>a</sub> values	ΔpK <sub>a</sub> range	Complexes	Rule	Ref.
4-Substituted benzoic acids/4-substituted pyridines	Calculated from ACD Labs	−2.94 to 6.1	22 cc, 11 salts	−1 < ΔpK <sub>a</sub> < 4	15c
Di- and tricarboxylic acids/bipyridines and isonicotinamide	Literature	−2.95 to 2.90	13 cc, 3 salts	0 < ΔpK <sub>a</sub> < 3.75	21
Gentisic acid/21 pyridines	Aqueous solutions	−0.7 to 4.7	5 cc, 16 salts	2 < ΔpK <sub>a</sub> < 2.5	22
29 Acids/2-aminopyrimidine	Calculated from ACD Labs	−1.08 to 3.77	17 cc, 8 salts	0 < ΔpK <sub>a</sub> < 2	23
Pyridine and 4-dimethylaminopyridine/5 dicarboxylic acids	Aqueous solutions	1.68 to 7.78	2 cc, 7 salts	0 < ΔpK <sub>a</sub> < 3	25

rule as used in this study. However, for the combination of fumaric acid with 4-dimethylaminopyridine, the molecular salt formed with fumarate also has a neutral fumaric acid molecule in the crystal structure. The difference in pK<sub>a</sub> is 6.68 and thus shows that the solid state complex that is formed can violate the empirical rules being used.

In conclusion, this study, looking at a limited matrix of one carboxylic acid with 9 pyridines, corresponds exactly with the ΔpK<sub>a</sub> rule, forming co-crystals below 0 and salt above 3 and the intermediate range favourable for both. A further study of already known complexes featuring carboxylic acids and pyridine complexes shows that the lower and upper limits are in perfect agreement for the functional groups. Complexes approaching the 0 and 3 endpoints show no favouritism to co-crystals over salts.

The National Research Foundation National Equipment Programme (UID: 78572) is thanked for financing the purchase of the single-crystal diffractometer.

## Notes and references

‡ (i) A typical example of the synthesis of the complexes is given for 1: 0.100 g of 2-chloro-4-nitrobenzoic acid (0.496 mmol) and 0.078 g of 2-bromopyridine (0.496 mmol) was dissolved in 5 ml of AR-grade methanol and dissolved by gentle heating. Crystals were grown by slow evaporation. (ii) Data were collected using a Bruker Venture D8 Photon CMOS diffractometer with graphite-monochromated MoKα<sub>1</sub> (λ = 0.71073 Å) radiation at −100 °C. H atoms involved in hydrogen bonding were located from the difference Fourier Map. (iii) All searches were done on the Version 5.34 with the November 2012 database. The search query used was any pyridine/pyridium and COOH/COO<sup>−</sup> functional groups on a phenyl ring on separate molecules, with general molecular formula C<sub>12–18</sub>H<sub>10–30</sub>N<sub>1–4</sub>O<sub>2–8</sub> and excluding any methanol or water solvates. This gave 173 hits, which was reduced to 109 after removing duplicate entries, unimolecular compounds, sulfonate salts, dicarboxylic molecules, dipyridines, esters, ammonium cations, amides, N-oxides molecules, and compounds with both functional groups on the same molecule. The filters applied to the search are: 3D coordinates determined, no powder structures, not disordered, no errors, R factor < 0.05, only organics. The conquest search query file with the 173 hits and pdf and the cif file containing the final 109 entries are provided in the ESI.†
