Semimetal-functionalised polyoxovanadates

Kirill Yu. Monakhov,*a Wolfgang Bensch*b and Paul Kögerler*ac

Polyoxovanadates (POVs), known for their wide applicability and relevance in chemical, physical and biological sciences, are a subclass of polyoxometalates and usually self-assemble in aqueous-phase, pH-controlled condensation reactions. Archetypical POVs such as the robust $[V_{18}^{\text{IV}}O_{42}]^{12-}$ polyoxoanion can be structurally, electronically and magnetically altered by heavier group 14 and 15 elements to afford Si-, Ge-, As- or Sb-decorated POV structures (heteroPOVs). These main-group semimetals introduce specific chemically engineered functionalities which cause the generally hydrophilic heteroPOV compounds to exhibit interesting reactivity towards organic molecules, late transition metal and lanthanoid ions. The fully-oxidised (V^V) , mixed-valent (V^V/V^{IV}) and (V^{IV}/V^{II}) , "fully-reduced" (V^{IV}) and "highly-reduced" (V^{II}) heteroPOVs possess a number of intriguing properties, ranging from catalytic to molecular magnet characteristics. Herein, we review key developments in the synthetic and structural chemistry as well as the reactivity of POVs functionalised with Si-, Ge-, As- or Sb-based heterogroups.

1. Introduction

1.1 General remarks

Although vanadium is best known for its use in the large-scale industrial production of alloys and steels, this group 5 transition metal also plays a significant role in biological systems and bioinorganic chemistry. 1,2 Vanadium shows common oxidation states between +2 and +5 revealed by characteristic colours such as lilac/purple (V^{2+}) , green (V^{3+}) , blue $(\{V^{IV}O\}^{2+})$, and yellow $(\{V^{V}O_{2}\}^{+})$ and $\{V^{V}O_{3}\}^{-}$ and exhibits a particularly rich coordination chemistry in aqueous solutions.^{3,4} It has a high tendency to

form oxovanadium ions whose nuclearity, structural motifs and net charge are strongly influenced by the specific reaction conditions such as stoichiometries and concentration of the reactants, pH (alkaline vs. acidic aqueous solutions), temperature, pressure, and reaction time. In general, vanadium oxide compounds find a wide range of applications in catalysis,5 biochemistry, 1,2,6 sol-gel chemistry, 2 gas sensing, 8 geochemistry, sorption¹⁰ and intercalated layered material,¹¹ surface and nano sciences¹² and perform their role as secondary electrode materials for advanced lithium ion batteries and vanadium redox-flow batteries. 13 Even in photosynthesis the role of vanadate and vanadyl citrate compounds was investigated. 14 The chemistry of polyoxovanadates (POVs),15 the latter being a subclass of polynuclear molecular early transition metal oxides known as polyoxometalates (POMs), 16 is a very fast growing area of research, mainly due to the versatile redox activities of POVs, 17 their current application and further perspectives in various branches of chemical, physical and biological sciences.

Kirill Monakhov received his Dr rer. nat. degree in 2010 with Prof. Gerald Linti (Heidelberg University, Germany). After two years as a postdoctoral fellow of the German Research Foundation and the Cercle Gutenberg with Prof. Pierre Braunstein (University of Strasbourg, France), and after being awarded the Academia Europaea Burgen Scholarship in 2011, he returned to Germany in 2013 with a DFG postdoctoral reintegration fellowship to join the group of Paul Kögerler at RWTH Aachen University. In 2015 he received a DFG Emmy Noether fellowship and now leads a junior research group at the Institute of Inorganic Chemistry at RWTH Aachen.

Wolfgang Bensch received his Dr rer. nat. with Prof. Eberhard Amberger at the Ludwig-Maximilians-University of Munich (Germany) in 1983. He was a postdoctoral fellow at the University of Zurich (Switzerland) and joined Siemens Company (Munich) in 1986. In 1990 he started his habilitation at the Johann Wolfgang Goethe University Frankfurt (Germany) which was finished in 1993. He was appointed as full professor for Inorganic Solid State Chemistry at the Christian-Albrechts-University Kiel in 1997.

1.2 Structure and characterisation of conventional POVs

Review Article

In aqueous and organic¹⁸ solutions, POVs are formed in pHdependent condensation reactions in which small [VO_n]^{Q-} fragments aggregate to form a large variety of high- and lownuclearity cluster structures with diverse coordination geometries of the vanadium cations. POVs usually exhibit cage-, sphere-, hollow-, basket-, belt-, and barrel-like structural motifs, 19 which are constructed of a number of polyhedra fused and/or linked through a common vertex (corner) and/or polyhedral edges and faces. These polyhedra consist of the homo- or heterovalent V atoms showing e.g. square-pyramidal²⁰ [VVO₅]⁵⁻ and [VIVO₅]⁶⁻, octahedral $[V^VO_6]^{7-}$ and $[V^{IV}O_6]^{8-}$ and tetrahedral $[V^VO_4]^{3-}$ coordination geometries. Thus, the adjustable coordination behaviour of V in POVs contrasts with the predominantly octahedral coordination environments of Mo and W ions in their POM structures. One of the most studied and structurally characterised POVs is the orange-coloured decavanadate ion, 21 $[V_{10}O_{28}]^{6-}$ (Fig. 1), that demonstrates the ability to build supramolecular assemblies²² and shows fascinating biological activity.²³ This polyanion, reported for the first time in 1956, has also been found in minerals (see, e.g. lasalite, Na₂Mg₂[V₁₀O₂₈]·20H₂O).²⁴

POVs can be divided into four general families: fully-oxidised (V^V), mixed-valent (V^V/V^{IV} or V^{IV}/V^{III}), "fully-reduced" (V^{IV}) and "highly-reduced" (V^{III}) species. The following crystallographically characterised POVs $[V_2O_7]^{4-}$, 25 $[V_3O_9]^{3-}$, 26 $[V_4O_{12}]^{4-}$, 27 $[V_5O_{14}]^{3-}$, 28 $[V_{10}O_{28}]^{6-}$, 29 $[V_{12}O_{32}]^{4-}$, 30 $[V_{13}O_{34}]^{3-}$, 31 $[V_{15}O_{42}]^{9-}$, 32 $[V_{16}O_{42}]^{4-}$ oonstitute the class of fully-oxidised vanadium

Fig. 1 Polyhedral representation of structurally characterised fully-oxidised POVs with different topologies involving V ions in the formal oxidation states of +5. Oxygen positions are shown as small red spheres, the V^VO_x coordination polyhedra in orange colour.

Paul Kögerler graduated with a Dr rer. nat. degree with Prof. Achim Müller at the University of Bielefeld (Germany) in 2000, followed by a postdoctoral research stay at the Department of Physics and Astronomy at Iowa State University (USA). In 2003, he was appointed as a tenured Associate Scientist at the U.S. DOE Ames Laboratory, before returning to Germany in 2006 as Professor of Chemistry at the Institute of Inorganic Chemistry at RWTH Aachen University and Group Leader for Molecular Magnetism at the Peter Grünberg Institute, Research Centre Jülich.

Fig. 2 (a) $[V_{10}O_{26}]^{4-}$ with two V^{IV} (caps) and eight V^{V} atoms. (b) $[V_{17}O_{42}]^{4-}$ with five V^{IV} (four peripheral and one central) and twelve V^{V} atoms. Colour code: O, red; $V^{IV}O_{x}$, sky-blue polyhedra; $V^{V}O_{x}$, light-orange polyhedra.

species (Fig. 1). X-ray single-crystal structures have been determined for $[V_2^{IV}V_8^VO_{26}]^{4-,34}$ $[V_8^{IV}V_7^VO_{36}]^{5-,35}$ $[V_{11}^{IV}V_5^VO_{38}]^{7-,36}$ $[V_3^{IV}V_{13}^VO_{42}]^{7-,37}$ $[V_5^{IV}V_{12}^VO_{42}]^{4-,38}$ $[V_{16}^{IV}V_2^VO_{42}]^{10-,39}$ $[V_{10}^{IV}V_8^VO_{42}]^{4-,39}$ $[V_8^{IV}V_{10}^VO_{44}]^{6-,40}$ $[V_6^{IV}V_{13}^VO_{49}]^{9-,41}$ $[V_8^{IV}V_{14}^IO_{54}]^{6-,40}$ $[V_{16}^{IV}V_{18}^VO_{82}]^{10-42}$ (disregarding encapsulated supramolecular guest species) from the class of the mixed-valent V^V/V^{IV} species (Fig. 2). The mixed-valent V^{IV}/V^{III} -POVs and the "highly-reduced" V^{III} -POVs consist mostly of a variety of vanadium alkoxide structures. 43,44 The most renowned representative in the class of the "fully-reduced" POVs is the $[V_{18}^{IV}O_{42}]^{12-}$ polyoxoanion whose chemical and structural characterisation were reported for the first time by Johnson and Schlemper in 1978 (Fig. 3). 45 The $\{V_{18}O_{42}\}$ architecture constructed from the edge-sharing square-pyramidal $\{O = VO_4\}$ units represents an archetypal structure with a diameter of ca. 11 Å which may adopt idealised T_d and D_{4d} symmetries. The strong infrared stretching frequencies of terminal V = O groups characteristically appear in the range 940–1000 cm $^{-1}$.

The presence of heterovalent vanadium atoms in some POVs occasionally complicates the assignment of the positions of the individual V atoms. This is due to the multifaceted nature of the POV structures, which often afford similar coordination geometries (*e.g.* square-pyramidal) around the V^V/V^{IV} ions and feature charges which are delocalised over the vanadium centres. Generally, there are several approaches to assign the oxidation states of V atoms in the entire POV structure: (i) overall charge balance, (ii) calculation of bond valence sums from determined bond lengths, ⁴⁶ (iii) redox titration and (iv) X-ray photoelectron spectroscopy (XPS). Elemental, thermal (TG-DTA), ⁴⁷ X-ray powder diffraction and electron microprobe (EMP) analyses, infrared (IR) spectroscopy, electron paramagnetic resonance spectroscopy (EPR),

Fig. 3 Schematic decomposition of the "fully-reduced" $[V_{18}O_{42}]^{12^-}$ POV into the $\{V_{18}^{V}\}$ skeleton and the $\{O_{24}\}$ polyhedron of bridging oxygen sites (rhombicuboctahedron). Colour code: O, red; V^{IV} , sky blue; $V^{IV}O_x$, sky-blue polyhedra.

¹H, ¹⁷O and ⁵¹V nuclear magnetic resonance spectroscopy (NMR), 48 energy-dispersive X-ray spectroscopy (EDXS), ultravioletvisible (UV-vis) spectroscopy, electrospray ionisation mass spectrometry (ESI-MS), 49 cyclic voltammetry (CV), and inelastic neutron scattering (INS) have been used for the chemical and structural characterisation of POVs. Temperature- and fielddependent magnetic susceptibility measurements were routinely applied to evaluate the magnetic characteristics of reduced POVs. A study combining density functional theory (DFT) calculations and ⁵¹V NMR experiments for [V₁₀O₂₈]⁶⁻ was published some time ago. 50 More recently, joint experimental and computational studies have been performed on positively-charged vanadium oxide clusters in the gas phase and in solution. These involved e.g. the combination of laser desorption time-of-flight mass spectrometry, UV-vis and IR spectroscopy, and DFT calcula-

tions, 51 or analysis by ESI-MS, collision-induced dissociation

1.3 Relation of POVs to classical POMs

experiments and DFT.52

Chem Soc Rev

The POV structures are usually derived or deduced from transferable vanadium oxoanion building blocks and host-guest aggregates, but also from small stable POM archetypes. Although the redox behaviour of the POVs differs from that of POMs comprised of group 6 transition metals (M = Mo, W), some of the construction principles of the metal-oxide core frameworks are very similar between these two classes of compounds. The POVs have thus been shown to adopt the structures of the classical Lindqvist-type [M₆O₁₉]^{Q-} polyanions,⁵³ as exemplified by the mixed-valent $[V_6O_{19}]^{Q-}$ polyoxoanions, 54 and to exhibit expanded Keggin-type [YM₁₂O₄₀]^{Q-} structures (Y: heteroatom).⁵⁵ A first representative in the latter family, a fully-oxidised $[PV_{14}O_{42}]^{9-}$ POV, which is composed of an α -Keggin $[PV_{12}O_{40}]^{15-}$ polyoxoanion capped by two VO3+ moieties, was reported in 1980.⁵⁶ A mixed-valent bicapped polyoxomolybdate Keggin-type polyoxoanion with two $\{VO\}^{2+}$ caps,⁵⁷ $[PMO_6^VMO_6^{VI}O_{40}(V^{IV}O)_2]^{5-}$, is of interest due to its isostructural relations with the fullyoxidised [V₁₅O₄₂]⁹⁻ isopolyoxovanadate. So-called superkeggin structures based on the {V18O42} constituents have been found for the mixed-valent complexes $[V_{12}^{IV}V_6^VO_{42}(SO_4)]^{8-58}$ $[V_{18}^{IV}O_{42}H_9(V^VO_4)]^{6-,58}$ and $[V_{14}^{IV}V_4^VO_{42}(PO_4)]^{11-.59}$ Note that the structure of the archetypal "fully-reduced" $[V_{18}^{IV}O_{42}]^{12-}$ polyoxoanion with D_{4d} symmetry can formally be derived stepwise from the fully-oxidised α -Keggin-type framework $[V_{12}^VO_{36}]^{12-}$, as illustrated in Fig. 4.

1.4 'Host-guest' complexation in POV chemistry

The cage-, basket-, barrel- and sphere-like shape of highnuclearity POVs enables them to entrap small guest species⁶⁰ in their central voids, in a manner that is structurally reminiscent of the "molecular container" behaviour of e.g. fullerenes. The case of a discrete (small) number of water molecules enclosed in a molecular container generally is of great interest: Jung and coworkers e.g. emphasise that "a single water molecule within an isolated space is a hot research topic in molecular science, owing to potential applications to delicate functions such as proton transfer, tautomerism, recognition, and biological systems". 61,62

Fig. 4 Schematic structural evolution of the fully-oxidised α -Keggin-type framework $[V_{12}O_{36}]^{12-}$ towards the "fully-reduced" $[V_{18}O_{42}]^{12-}$ POV via formation of the bicapped Keggin structure $[V_{14}O_{38}]^{6-}$ and the hypothetical $[V_{18}^{V}O_{42}]^{6+}$ structure, the latter here assumed as isostructural to $[V_{18}^{IV}O_{42}]^{12-}$. Colour code as in Fig. 2 and 3.

Fig. 5 The H_2O -endohedral (@) complexes of C_{60} (a), ⁶⁵ the "fully-reduced" $[V_{18}O_{42}]^{12-}$ POV (b), 45,64 and $[Pd_3L_2]^{6+}$ (c). 61 C, grey; N, blue; O, red; V^{IV} , sky blue; Pd, brown.

Fig. 5 illustrates that not only Pd(II) cage-type coordination complexes⁶¹ and fullerene C₆₀,⁶³ but also the hydrophilic POVs are able to host an individual H2O molecule.64 In the following, for reasons of clarity we indicate the supramolecular encapsulation state of a guest species by the "@" notation when specifying the composition of a discrete polyanion, whereas in full formulas for POV-based compounds the guest species is simply set in brackets.

The prototypical fully-oxidised, mixed-valent and "fullyreduced" POV shells (e.g., bowl-like {V12O32}, nearly spherical D_{4d} { $V_{18}O_{42}$ }, ellipsoidal D_{2h} { $V_{18}O_{44}$ }, bulb-shaped D_{2d} { $V_{22}O_{54}$ }) were found to enclose not only water molecules but also anions (e.g., Cl⁻, Br⁻, I⁻, HCOO⁻, MeCOO⁻, CN⁻, CO₃²⁻, NO⁻, NO₂⁻, N_3^- , PO_4^{3-} , SH^- , SCN^- , SO_3^{2-} , SO_4^{2-} , ClO_4^- , and VO_4^{3-}) within the vanadium oxide shells.^{39,66} Larger neutral guests (methanol, ethanol, ethane-1,2-diol) have furthermore been reported to exist in phosphate- and diaminopropane-capped $\{V_3^{III}V_{18}^{IV}\}$ -type cluster shells.⁶⁷ In all of these compounds, the encapsulated halide, pseudohalide, inorganic or organic guest anion interacts with the anionic host shell solely via weak electrostatic and van der Waals forces at distances of ca. 3.5-4.0 Å. In this regard, the POV host structures⁶⁸ can also be regarded as

Review Article Chem Soc Rev

vanadium oxide matrices that isolate unstable guests with short lifetimes or high reactivities. The formation of POV host shells can also be controlled by templating effects of small guest anions present in solution. 40,69 Interestingly, also certain cationic groups such as dimethylammonium that weakly bind to polyoxovanadate shell structures can assume the role of an interchangeable template as well, for example in the POV $[Cl@V_{12}^{V}O_{32}(H_2NMe_2)_2]^{3-}$ where one or both dimethylammonium groups can subsequently be exchanged by first-row transition metal cations.⁷⁰ Macrocyclic, highly-oxidised POV structures $[PdV_6^VO_{18}]^{4-}$, $[Cu_2V_8^VO_{24}]^{4-}$, and $[Ni_4V_{10}^VO_{30}(OH)_2(H_2O)_6]^{4-}$ incorporating transition-metal cationic templates (Pd²⁺, Cu²⁺, and Ni²⁺) are also known. 15,71

The far-reaching consequences for the properties of the host matrix are exemplified by a family of purely inorganic hostguest assemblies $[X@HV_8^{IV}V_{14}^VO_{54}]^{6-}$ (X = $VO_2F_2^-$, SCN⁻, and ClO₄⁻).⁷² Here the nature of the guest (X) anion defined the magnetic and electrochemical characteristics of the virtually isostructural, mixed-valent V^V/V^{IV}-POV host matrices. Similarly, template-dependent reactivity has also been observed for the photooxidation of an organic dye by nearly isostructural $[X@(Bi(dmso)_3)_2V_{12}^VO_{33}]^-$ -type POVs $(X = Cl^-, Br^-)$. In general, POVs exhibiting host-guest relationships consist of transferable substructures and exist in a variety of reduction (and protonation) states. In the words of Müller et al.: "The template syntheses of new cluster compounds utilizing intrinsic host-guest relationships open up new possibilities for chemists to create nanosized host or cluster structures with novel magnetic properties".74

1.5 Magnetism of POVs

The POVs can be magnetically functionalised either via their reduction towards the mixed-valent, "fully-reduced", and "highlyreduced" structures comprising vanadyl {V^{IV}O}²⁺ (isotropic spin-1/2) and {VIIIO}+ (spin-1) groups or via incorporation of paramagnetic transition metal or lanthanoid cations. The last few decades have shown that such POVs are ideal objects for magnetochemical studies⁷⁵ and the exploration of nanoscale molecular magnetism⁷⁶ due to their intriguing magnetic features, ranging from geometrical spin frustration to single-molecule magnet characteristics.⁷⁷ Most commonly, the mixed-valent (V^V/V^{IV} or V^{IV}/V^{III}), "fully-reduced" (d¹-V^{IV}) and "highly-reduced" (d²-V^{III}) vanadium spin-centres are coupled antiferromagnetically via bridging oxygen atoms, although ferromagnetic coupling between the vanadium ions is also possible, as has been forecasted in a quantum-chemical study of the synthetically readily accessible mixed-valent alkoxo-hexavanadates of the $[V_4^{IV}V_2^VO_7(OR)_{12}]$ type. ⁷⁸ A comparative theoretical study of the magnetic properties of a homovalent $[V_{18}^{IV}O_{42}]^{12-}$ POV with 18 fully localised valence electrons and its structurally identical mixed-valent derivative $\left[V_{10}^{IV}V_{8}^{V}O_{42}\right]^{4-}$ with 10 partially delocalised electrons explored the role of electron transfer processes and magnetic exchange interactions in these structures.⁷⁹ The preparation of the first water-soluble salt-inclusion solid $[Cs_{11}Na_3(V_{15}O_{36})Cl_6]$ containing the mixed-valent $[V_{11}^{IV}V_4^VO_{36}Cl]^{9-}$ building block is an interesting result in view of the development of "quantum magnetic solids within extended systems". 80,81

Notably, the chemical reactivity and acid-dissociation constants of fully and partly reduced POVs can in principle be influenced by the extent of charge delocalisation.

1.6 Catalysis with POVs

The catalytic activity of the POV-based compounds was demonstrated by a number of authors. Gao and Hua reported that $K_7[Ni^{IV}V_{13}O_{38}]\cdot 16H_2O$ containing the fully-oxidised $[V_{13}^VO_{38}]^{11-}$ building block catalyses oxidative mineralisation of p-nitrophenol and p-chlorophenol into CO₂, NO₃⁻, and Cl⁻ using 30% aqueous H₂O₂ as oxidant under mild conditions. 82,83 Khan and coworkers investigated the selective catalytic reduction of nitrogen oxides into N₂ by propylene as the reductant using the mixed-valent heterometallic compounds $\text{Li}_6[M_3(H_2O)_{12}V_{18}O_{42}(YO_4)]\cdot 24H_2O$ $(M = Mn^{II}, Ni^{II}; Y = V, S)$ and $[M_3(H_2O)_{12}V_{18}O_{42}(YO_4)]\cdot 24H_2O$ $(M = Fe^{II}, Co^{II}; Y = V, S)$ as precursors.⁸⁴ The catalytic oxidative dehydrogenation of propane by the nanostructured compounds $[M_3(H_2O)_{12}V_{18}O_{42}(YO_4)]\cdot 24H_2O$ (M = Fe, Co, Mn; Y = V, S) has also been studied.85 Wu et al. showed that the compound $(NH_4)_2[\{Mn(salen)(H_2O)\}_6V_6O_{18}](NO_3)_2\cdot30H_2O (salen^2 = N,N'-1)$ (ethylene)bis(salicylideneiminate)), the structure of which comprises a cyclic POV anion decorated with six MnIII-salen Schiff-base complex groups, acts as photocatalyst for organic dye degradation.86 Chakrabarty and Banerjee studied the decomposition of H₂O₂ into O₂ and H₂O, which is catalysed by the $[Mn^{IV}V_{13}^VO_{38}]^{7-}$ polyoxoanion in aqueous acetate buffer.⁸⁷ The compound $(NH_4)\{[Zn_4(dach)_7(H_2O)_3][V_3V_{18}P_6O_{60}(dach)_3]\}\cdot 19H_2O$ $(dach = (\pm)-trans-1,2-cyclohexanediamine = C_6H_{14}N_2)$ containing the nanoscale, highly-reduced $[V_3^{\rm III}V_{18}^{\rm IV}P_6O_{60}({\rm dach})_3]^{9-}$ building block was shown to selectively catalyse styrene oxidation in the presence of H₂O₂.⁴⁴ (N_nBu₄)₄[V₁₆O₃₈(Br)] containing the mixedvalent [Br@V₇^{IV}V₉^VO₃₈]⁴⁻ building block exhibited catalytic activity in the oxidative bromination reactions of aromatic substrates under aerobic conditions. 88 The mixed-valent $(N_nBu_4)[V_5^{IV}V_1^VO_7(OMe)_{12}]$ compound was demonstrated to catalyse photoinduced water oxidation.89

1.7 Scope of the review

Embedding heteroelements into POV structures 90 allows us to alter the electronic and magnetic properties, as well as the electrical conductivities 91 of the resultant heteropolyoxovanadate (heteroPOV) spin structures (reminiscent of "doping" semiconducting materials) through the interplay between stoichiometries, heavy atom effects and redox potentials as well as steric and electronic environment around the terminal V=O groups. Herein, we place emphasis on the structural variety of silicato-, germanato-, arsenato-, and antimonato-derivatised polyoxovanadates and their hybrid compounds with middle and late transition metals and discuss interesting molecular features and application perspectives of these heteroPOVs. Great interest in the polynuclear molecular vanadium oxides decorated with the heavier group 14 and 15 elements (E) is generated by the specific synthetic, structural, host-guest and vast redox chemistry and extraordinary magnetic characteristics of these compounds, involving e.g. geometrical spin-frustration.92 Remarkably, the structurally, electronically and spin density-modified heteroPOVs

introduce different functionalities linked to the main-group metalloid atoms (E = Si, Ge, As, Sb) that may act as bonding mediators. The steric requirements around terminal V=O groups in the heteroPOVs differ between the building blocks comprising E = Si^{IV}, Ge^{IV} and those with E = As^{III}, Sb^{III} due to the presence of lone electron pairs at the latter elements. The fully-oxidised (VV), mixed-valent (VV/VIV and VIV/VIII), "fullyreduced" (VIV), and "highly-reduced" (VIII) heteroPOVs with various point-group symmetries and different isomeric structures of α and β types show an astonishing propensity for organic and transition metal/lanthanoid functionalization. This grants access to multifunctional inorganic-organic supramolecular materials93 and the closely-related chemistry of metal-organic frameworks (MOFs)94 and thus offers potential for applications of heteroPOVs in catalysis, surface science, and information technology.

2. Group 14 (Si, Ge) elementfunctionalised POVs

2.1 Preview

The chemistry of heteroPOVs incorporating the most common $\{E_2O_7\}$ groups and more rare $\{E_2O_5S_2\}$ ones with E = Si or Ge(SiPOVs and GePOVs) is still underdeveloped. In their molecular structures, the E^{IV} atoms usually favour four-fold coordination, thus yielding tetrahedral {EO₄} geometries. However, an example of a heteroPOV with a GeIV centre adopting a six-fold {GeO₆} coordination was also described. Interestingly, the Si-O and Ge-O bond lengths ($d_{E-O} = 1.56-1.79 \text{ Å}$) are comparable to the bond lengths of terminal V=O groups $(d_{V=O} = 1.56-1.64 \text{ Å})$, but shorter when compared to the single V-O bonds (d_{V-O} = 1.88–2.28 Å). The $\{E_2O_7\}$ - or $\{E_2O_5S_2\}$ -decorated POV structures are typically viewed as being formally derived from the $[V_{18}^{IV}O_{42}]^{12-}$ archetype. The family of polyoxovanadatosilicates (SiPOVs) is represented by the assemblies with nuclearity V_{15} , V_{17} and V_{18} . The polyoxovanadatogermanates (GePOVs) display a series of assemblies classified as V_6 , V_9 , V_{12} , V_{14} , V_{15} and V_{16} . The SiPOVs and GePOVs usually encapsulate discrete water molecules or halide ions and can exhibit negative charges up to 12-. The SiPOVs (Table 1) and GePOVs (Table 2) are usually synthesised by hydrothermal or solvothermal reactions using V₂O₅, VOSO₄ and NH₄VO₃ as precursors.

2.2 Polyoxovanadatosilicates (SiPOVs)

Only a few studies describing the isolation of SiPOVs have been performed so far. These SiPOVs constitute a series with the general formula $\{V_{18-z}Si_{2z}O_{42+2z}\}$ and are characterised by antiferromagnetic coupling between the spin-1/2 vanadyl {VO}²⁺ moieties.

2.2.1 SiPOVs with one-dimensional (1D) structures

Vanadyl(v)-extended SiPOVs. The first report about the spherical POV chemically modified with Si^{IV} dates back to 2001 when Jacobson and coworkers described the $[V_{16}^{IV}Si_4O_{46}]^{12-}$ polyoxoanion (Fig. 6a) that is a component of the compound $Cs_{10.5}[(V_{16}O_{40})(V_{1.5}Si_{4.5}O_{10})] \cdot 3.5H_2O$ synthesised under hydrothermal

Fig. 6 Polyhedral representations of the "fully-reduced" SiPOVs $[V_{16}^{IV}Si_{a}O_{a6}]^{12-}$ (a), $\alpha - [H_4 V_{14}^{IV} O_{44} (SiO)_8]^{12-}$ (b), and $[V_{15}^{IV} Si_6 O_{42} (OH)_6]^{6-}$ (c). Encapsulated $H_2 O$ (a and b), Cl⁻ (c), and hydrogen atoms are not shown. Colour code: Si, violet; O, red spheres; VIVOx, sky-blue polyhedra.

Fig. 7 Representation of the extended structures of SiPOVs covalently linked by inorganic groups.

conditions (Table 1).95 The crystal structure of this hybrid compound shows a 1D linear chain of the "fully-reduced" [V₁₆V₀₄₀]¹⁶⁻ POVs interlinked by vanadosilicate six-membered rings with the composiiton $\{V_{1.5}^{V}Si_{4.5}O_{10}\}^{5.5+}$ (Fig. 7a). $[V_{16}O_{40}]^{16-}$ is hypothetically derived from the α -Keggin $\{V_{12}O_{36}\}$ archetype or, accordingly, the {V₁₈O₄₂} archetype (Fig. 4). Replacing two vanadyl ${VO}^{2+}$ groups on two opposite sides of the ${[V_{18}O_{42}]^{12-}}$ isopolyoxoanion by two silicate {Si2O3} subunits, the spherical [V₁₆^{IV}Si₄O₄₆]¹²⁻ dodecaanion is formed. A water molecule is located in the void of the polyoxoanion.

Later on, two extended chains based on the "fully-reduced" {V₁₅^{IV}Si₆O₄₈} building blocks⁹⁶ were obtained from reactions under hydrothermal conditions where the pdn molecules (pdn = 1,3-propanediamine) acted as reductant for VV (Table 1). These two inorganic-organic hybrid compounds can be assigned to the classes of vanadyl-extended and transition metal complex (TMC)supported SiPOVs.

1D zig-zag chains of the SiPOVs doubly bridged by the fullyoxidised {VVO₂}+ moieties through (Si-)O-V-O(-Si) bonds with $d_{V-O} = 1.79 \text{ Å}$ and 1.81 Å (Fig. 7b) were observed in the crystal of the compound $(H_{1.5}pdn)_6[\{H_2V_{15}Si_6O_{48}(Cl)\}(VO_2)_2]\cdot 4H_2O.$ The partially protonated pdn molecules compensate the high negative charge of the mixed-valent $[\{Cl@H_2V_{15}^{IV}Si_6O_{48}\}(V^VO_2)_2]^{9-}$ assembly and reside in the voids between the zig-zag chains, along with H2O solvate molecules.

TMC-supported SiPOV. One-dimensional infinite chains of $[H_6V_{15}^{IV}Si_6O_{48}]^{6-}$ polyoxoanions that are singly bridged by [Co(pdn)₂(H₂O)]²⁺ fragments through (V–)O–Co–O(–Si,V) linkages (Fig. 7c) were found in the crystal structure of (H₂pdn)(Hpdn)₂- $[H_6V_{15}Si_6O_{48}][Co(pdn)_2(H_2O)]\cdot 9H_2O.^{96}$

Review Article Chem Soc Rev

2.2.2 SiPOV with three-dimensional (3D) structures. In 2003, Clearfield and coworkers described a 3D cross-linked structure consisting of the $[H_4V_{14}O_{44}(SiO)_8]^{12-}$ building blocks bridged by {(VO)O2N2} pyramids that are covalently interconnected by bidentate dab ligands (dab = 1,4-diaminobutane) through the V^{IV} ions (Fig. 7d). 97 The "fully-reduced", $\alpha\text{-}[H_4V_{14}^{IV}$ $O_{44}(SiO)_8$ ¹²⁻ polyoxoanion (Fig. 6b) with idealised D_{2d} symmetry is a component of the hydrothermally prepared compound $[H_4V_{18}O_{46}(SiO)_8(dab)_4(H_2O)]\cdot 4H_2O$ (Table 1). This SiPOV shows a modified [V₁₈O₄₂]¹²⁻ structure where four {VO₅} square pyramids are substituted by four handle-like {Si₂O₇} silicate units. Each of these units is made up of two corner-sharing $[SiO_4]^{4-}$ tetrahedra. The POV shell is constructed of an octagonal ring sharing two crescent-type {VO₅} chains fused to each side of the former and exhibits non-bonding V···V distances of 2.83-3.09 Å.

2.2.3 Discrete SiPOV within hydrogen bonding networks. The formal replacement of three {VO₅} square pyramids in the {V₁₈O₄₂} archetypal structure with three partially protonated handle-like {Si₂O₅(OH)₂} groups results in the D₃-symmetrical $[V_{15}^{IV}Si_6O_{42}(OH)_6]^{6-}$ polyoxoanion (Fig. 6c) found as the central building block in the hydrothermally prepared compound $(H_2pdn)_3(Hpdn)[V_{15}Si_6O_{42}(OH)_6(Cl)]\cdot nH_2O \ (n = 7-10) \text{ with a}$ solid-state close-packed layer aggregate structure (Table 1).98 Here, the discrete SiPOV $[Cl@V_{15}^{IV}Si_6O_{42}(OH)_6]^{7-}$ exhibits closest intracluster V···V distances of ca. 3.0 Å and hosts a Cl⁻ anion. In the crystal structure, extensive N-H···O hydrogen bonding interactions were observed, which interlink the pdn groups and the "fully-reduced" SiPOVs. Notably, these N-H...O hydrogen bonds are crucial in the formation of the supramolecular network structure.

2.2.4 Corollary for SiPOVs. All above-mentioned SiPOVs can be regarded as derivatives of the $[V_{18}O_{42}]^{12-}$ archetype (Fig. 3), as a specific number (n = 2-4) of its $[VO_5]^{6-}$ square pyramids are formally replaced with an equal number of handle-like silicate $[Si_2O_7]^{6-}$ iso-anionic or partly protonated $[Si_2O_5(OH)_2]^{4-}$ groups. All discussed "fully-reduced" SiPOV building blocks were shown to form diverse networks (Fig. 7) in the solid state principally due to the following points: (i) the chemical composition and structures of the inorganic linkers and the nature of the metal ions, which played a crucial role in the self-assembly behaviour of the spherical SiPOVs; (ii) the presence of the silicate groups in SiPOVs which are involved in the covalent bonding to the linking groups. As it was noted, "the interconnection of polyoxometal building blocks like polyoxovanadates by means of covalent bonds could create new porous materials with ultralow framework densities and high porosity".99 In view of the structural arrangement and organisation of the extended solid-state structures discussed above, it appears highly desirable to explore the role of the SiPOV-based networks as microporous molecular materials resembling zeolites or molecular sieves, e.g., for catalytic performance, gas storage, and ion exchange.

2.3 Polyoxovanadatogermanates (GePOVs)

2.3.1 Discrete GePOVs with $\{Ge_2O_7\}$ and partially protonated germanate groups. The chemical and structural characterisation of the first GePOVs dates back to 2003, when Jacobson and

Fig. 8 Polyhedral representations of the "fully-reduced" GePOVs $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-} \text{ (a), } \alpha - [V_{14}^{IV}Ge_8O_{50}]^{12-} \text{ (b), } \alpha - [V_{14}^{IV}Ge_8O_{42}S_8]^{12-} \text{ (c), and } \alpha - [V_{14}^{IV}Ge_8O_{42}S_8]^{12-} \text{ (d), } \alpha - [V_{$ $[H_2V_9^{IV}Ge_6O_{26}(L)_6]^{2-}$ (d). Encapsulated water molecules and hydrogen atoms are not shown. Colour code: C, grey; Ge, green; O, red spheres; V^{IV}O_x, sky-blue polyhedra

coworkers described the compounds Cs₈[V₁₆Ge₄O₄₂(OH)₄]·4.7H₂O, $(H_2ppz)_4(Hppz)_4[V_{14}Ge_8O_{50}(H_2O)]$ (ppz = piperazine, $C_4H_{10}N_2$) and K₅[H₈V₁₂Ge₈O₄₈(SO₄)]·10H₂O, which were synthesised under hydrothermal conditions (Table 2). 100 These compounds are based. respectively, on the "fully-reduced" $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ (Fig. 8a) and $\alpha - [V_{14}^{IV}Ge_8O_{50}]^{12-}$ polyoxoanions (Fig. 8b) and the mixed-valent $[H_8V_{12}Ge_8O_{48}(SO_4)]^{5-}$ polyoxoanion that encloses a sulfate template anion in the centre of a spherical GePOV shell. The structures of $[V_{16}Ge_4O_{42}(OH)_4]^{8-}$ and $[H_8V_{12}Ge_8O_{48}(SO_4)]^{5-}$ are derived from the "fully-reduced" $[V_{18}^{IV}O_{42}]^{12-}$ shell (i.e., Keggin-type $[V_{12}^{IV}O_{36}]^{24-} + 6\{V^{IV}O\}^{2+}$ caps) on substitution of $\{VO\}^{2+}$ caps in the latter by a certain number of $\{Ge_2^{IV}O(OH)_2\}^{4+}$ dimeric units (two and four, respectively). To get to the final composition of $[H_8V_{12}Ge_8O_{48}(SO_4)]^{5-}$, two further $\{VO\}^{2+}$ caps in $[V_{18}^{IV}O_{42}]^{12-}$ are formally omitted. Similarly, replacing four {VO}²⁺ caps in the archetypal structure by four $\{Ge_2^{IV}O_3\}^{2+}$ groups affords the polyoxoanion cage of the composition [V₁₄Ge₈O₅₀]¹²⁻. It is interesting to note that the $[V_{14}Ge_8O_{50}]^{12-}$ and $[H_8V_{12}Ge_8O_{48}(SO_4)]^{5-}$ constituents are the structural analogues to the family of the polyoxovanadoarsenates with the general formula $[V_{18-z}As_{2z}O_{42}(Y)]^{m-1}$ $(Y = SO_3, SO_4, Cl; z = 3, 4)$, which are discussed below. In contrast to the structures of $[V_{14}Ge_8O_{50}]^{12-}$ and $[H_8V_{12}Ge_8O_{48}(SO_4)]^{5-}$ displaying rhombicuboctahedral topology, the molecular structure of $[V_{16}Ge_4O_{42}(OH)_4]^{8-}$ reveals an elongated square gyrobicupola topology.

The compound (H₂dab)₄[V₁₄O₄₄(GeOH)₈]·6H₂O was obtained by Clearfield and coworkers from the hydrothermal reaction between V₂O₅, GeO₂ and 1,4-diaminobutane (dab) in water (Table 2).⁹⁷ The "fully-reduced", protonated α - $[V_{14}^{IV}O_{44}(GeOH)_8]^{8-}$ polyoxoanion is isostructural to the aforementioned α - $[H_4V_{14}^{IV}O_{44}(SiO)_8]^{12-}$ polyoxoanion (Fig. 6b). In contrast to $[H_4V_{18}O_{46}(SiO)_8(dab)_4(H_2O)]\cdot 4H_2O$, the Ge(IV)-containing compound contains doubly protonated H₂dab²⁺ countercations.

A GePOV structural analogue to the $[Cl@V_{15}^{IV}Si_6O_{42}(OH)_6]^{7-}$ polyoxoanion (Fig. 6c) was also reported. The main structural difference between the two compounds containing the $[Cl@V_{15}E_6O_{42}(OH)_6]^{7-}$ component is the packing of the structural

building blocks. The compound with E = Si shows a closepacked layer structure, whereas the one with E = Ge exhibits a 1D chain structure. 98 The crystal structure of the GePOV-based compound (Table 2) with the formula (H2tren)2(H3tren)-[V₁₅Ge₆O₄₂(OH)₆(Cl)]-2H₂O is furthermore characterised by the N-H···O hydrogen bonds formed between the oxygen atoms of the "fully-reduced" polyoxoanions and the organic tris-(2-aminoethyl)amine (tren) countercations.

The compound $(H_3aep)_4[V_{14}Ge_8O_{50}]\cdot 2(aep)\cdot 13H_2O$ (aep = 1-(2-aminoethyl)piperazine = $C_6H_{15}N_3$) and the already described $(H_2ppz)_4(Hppz)_4[V_{14}Ge_8O_{50}(H_2O)]$ compound with the "fullyreduced" α-[V₁₄^{IV}Ge₈O₅₀]¹²⁻ components were formed in solvothermal reactions involving Cu(NO₃)₂·3H₂O below 150 °C and above 150 °C, respectively (Table 2). 101 Since Cu2+ was reduced to metallic Cu during the syntheses, the linking of the GePOV building blocks through Cu²⁺-centred complexes into extended structures was unsuccessful. Interestingly, (H₃aep)₄[V₁₄Ge₈O₅₀] 2(aep)·13H₂O could also be produced without utilising the copper salt Cu(NO₃)₂·3H₂O. However, the presence of copper in the reaction mixture turned out to be crucial for the crystallisation of (H₂ppz)₄(Hppz)₄[V₁₄Ge₈O₅₀(H₂O)]. The high negative charge of $\left[V_{14}^{IV}Ge_{8}O_{50}\right]^{12-}$ (Fig. 8b) is compensated by the protonated amine molecules. Weak (>2 Å) and strong (<2 Å) N-H···O hydrogen bonds between the organic ammonium countercations and the exposed oxygen atoms of the GePOVs in the crystals of both compounds result in 3D H-bonded networks. The preliminary analysis of the magnetic properties of (H₃aep)₄[V₁₄Ge₈O₅₀]·2(aep)·13H₂O indicated strong antiferromagnetic exchange interactions between the spin-1/2 vanadyl {VO}²⁺ moieties through the near-linear V-μ-O-V and bent $V(-\mu-O-)_2V$ bridges.

2.3.2 GePOVs with {Ge₂O₅S₂} groups

Discrete GePOV. The structural diversity of the GePOVs was explored towards their sulfur-functionalised analogues. Two polyoxothio compounds $(H_3 dien)_4[V_{14}Ge_8O_{42}S_8]\cdot 5H_2O$ (dien = diethylenetriamine) and (H3aep)4[V14Ge8O42S8] consisting of the "fully-reduced" $\left[V_{14}^{IV}Ge_{8}O_{42}S_{8}\right]^{12-}$ GePOVs and protonated amines as countercations were synthesised hydrothermally (Table 2). 99 The α -[$V_{14}^{IV}Ge_8O_{42}S_8$] $^{12-}$ polyoxoanion (Fig. 8c) with a diameter of ca. 7.4 Å shows structural, but not functional similarities to $\alpha - [V_{14}^{IV}Ge_8O_{50}]^{12-}$ (Fig. 8b). The $\{V_{14}\}$ -nuclearity building block of the thio-modified GePOV is composed of fourteen condensed {VO₅} square pyramids and eight tetrahedral {GeO₃S} units. Thus, eight terminal oxygens sites of four {Ge₂O₇} groups were formally exchanged for eight sulfur atoms to form four $\{Ge_2O_5S_2\}$ groups.

Cobalt-GePOV hybrid. Another example of thio-functionalised GePOV, $[H_2O@V_{15}^{IV}Ge_6O_{42}S_6]^{12-}$, composed of six slightly distorted $\{GeO_3S\}$ tetrahedra $(d_{Ge-S} = 2.09-2.14 \text{ Å})$, fifteen $\{VO_5\}$ square pyramids and an encapsulated central H2O molecule was obtained under hydrothermal conditions using metavanadate as precursor and elemental Ge, Co and S (Table 2).102 The spherical [V₁₅^{IV}Ge₆O₄₂S₆]¹²⁻ structure is constructed of three {V₇Ge₂O₂₄S₂} rings which are perpendicular to each other. This polyoxoanion is formally derived from the {V₁₈O₄₂} archetype

by substituting three $\{VO_5\}$ pyramidal units of $[V_{18}O_{42}]^{12-}$ by three handle-like {Ge₂O₅S₂} groups (for comparison, see $[V_{15}^{IV}Si_6O_{42}(OH)_6]^{6-}$ in Fig. 6c). This "fully-reduced" GePOV is further expanded by two {Co(tren)}²⁺ complexes through Co-S bonds, thus featuring the Co-S=Ge-O-V connections. These two trigonal-bipyramidal Co(II) complexes are attached to the terminal sulfide sites (S^{2-}) and, along with two [Co(tren)(H_2 tren)]⁴⁺ countercations, reduce the high negative charge of the polyoxoanion to give the compound [Co(tren)(H₂tren)]₂[{Co(tren)}₂- $V_{15}Ge_6O_{42}S_6(H_2O)$]-9H₂O where tren molecules act as mono- and tetradentate ligands. The presence of the N-H···O hydrogenbonding pattern in the crystal structure of this compound results in two differently oriented channels. Similar to other $\{V_{15}^{IV}E_6\}$ -type structures (see also Section 3.2.5), the magnetic structure of the GePOV building block can be described as being composed of a geometrically frustrated, antiferromagnetically coupled equilateral {V₃} triangle that is sandwiched between the two {V₆} hexagons characterised by strong antiferromagnetic nearest-neighbor coupling.

2.3.3 Discrete GePOV with alkoxo ligands. Wang and colleagues synthesised and characterised the first polyoxoalkoxovanadatogermanate (hereafter referred to as alkoxoGePOV). The compound $(NH_4)_2[H_2V_9Ge_6O_{26}(L)_6]\cdot 0.65H_2O$ $(H_2L = HOCH_2CH_2OH,$ ethylene glycol) was obtained from a solvothermal reaction 103 where ethylene glycol functioned as a reducing agent for NH₄VO₃ that was used as the vanadium source (Table 2). The "fully-reduced" $[H_2V_9^{IV}Ge_6O_{26}(L)_6]^{2-}$ species shows the cage-like structure consisting of six edge- and corner-sharing {VO₆} octahedra, three edge-sharing {VO₅} square pyramids, and six corner-sharing {GeO₄} tetrahedra (Fig. 8d). The six ethylene glycol oxygen-donor groups act as bridging alkoxide ligands. This alkoxoGePOV features the spherical {V₉Ge₆O₃₈} shell with approximate D_{3h} symmetry and experiences non-bonding V···V distances of ca. 3.07 Å. EPR studies performed on $(NH_4)_2[H_2V_9Ge_6O_{26}(L)_6]\cdot 0.65H_2O$ at room temperature revealed the presence of a partial delocalisation of nine unpaired 3d1 (V^{IV}) electrons in the alkoxoGePOV building block.

GePOV with a $\{GeO_6\}$ group. A mixed-valent $[V_2^{IV}V_{12}^{V}GeO_{40}]^{8-}$ polyoxoanion with an octahedrally coordinated Ge^{IV} heteroatom occupying a central geometrical position within the GePOV structure was isolated as the compound K₂Na₆[V₁₄GeO₄₀]·

2.3.4 Discrete GePOVs with two-electron reduced structures

10H₂O.¹⁰⁴ The compound was obtained by reaction of GeBr₂ and NaVO3 in aqueous acidic solution where GeBr2 acted as a reducing agent for the V^V source (Table 2). This D_{4h} -symmetric GePOV consists of a central {GeIVO6} octahedron and fourteen {VO₆} octahedra, all of which are edge-shared (Fig. 9). Interestingly, this polyoxoanion is the structural analogue to the $[V_2^{IV}V_{12}^VAl^{III}O_{40}]^{9-105}$ and $[V_2^{IV}V_{12}^VAs^VO_{40}]^{7-106}$ polyoxoanions; the Al-containing heteroPOV is found in the mineral sherwoodite, $Ca_{4.5}[V_{14}AlO_{40}]$. It is worth mentioning that the $[V_2^{IV}V_{12}^VGeO_{40}]^{8-}$ polyoxoanion extends the family of heteroPOVs where the main-group heteroatoms (E = Al^{III}, Ge^{IV}, As^V) reside within the {V₁₄O₄₀} cores. The dicapped cuboctahedral topology was ascribed to the $\{V_2^{IV}V_{12}^VEO_{40}\}$ building blocks. Magnetic studies of K₂Na₆[V₁₄GeO₄₀]·10H₂O showed that two apical spin-1/2

Review Article Chem Soc Rev

Fig. 9 Structure of the mixed-valent $[V_2^{IV}V_{12}^{V}GeO_{40}]^{8-}$ polyoxoanion, as present in $K_2Na_6[V_{14}GeO_{40}]\cdot 10H_2O$. Colour code: O, red; Ge, green; $V^{IV}O_{x}$, sky-blue polyhedra; V^{V} , light orange.

 V^{IV} ions, which are separated from each other by 8.52 Å *via* one O-Ge-O bond, are weakly antiferromagnetically coupled. X-band and Q-band EPR measurements indicated very weak spin-spin exchange coupling between these V^{IV} ions. The magnetic properties of the mixed-valent $[V_{14}GeO_{40}]^{8-}$ were theoretically studied by Suaud, Coronado and coworkers on the basis of model Hamiltonian calculations and wave function theory as well as an electric field approach. 107 In particular, it was shown that an external electric field can induce a reversible transition from a paramagnetic (triplet) to an antiferromagnetic (singlet) ground state configuration of $[V_{14}GeO_{40}]^{8-}$, meaning that this polyoxoanion can in principle act as a molecular switch. For a discussion about the relevance of $\left[V_{14}\text{GeO}_{40}\right]^{8-}$ to the field of molecular spintronics, see the review by Coronado and coworkers.⁷⁵ Moreover, the $[V_2^{IV}V_{12}^{V}GeO_{40}]^{8-}$ polyoxoanion was reported to be a two-electron catalyst for the oxidation of the coenzyme NADH at pH = 8. Note that POMs usually act as one-electron catalysts. 108

Neutral GePOV. Another two-electron reduced GePOV was reported by Bian, Dai and colleagues. 109 The mixed-valent compound [V₂^{IV}V₄^VGe₅O₂₁(heda)₆]·3H₂O, in which the deprotonated amine ligands [Hheda = N-(2-hydroxyethyl)ethylenediamine] coordinate covalently to the GePOV shell in three different coordination modes (monodentate and chelating for V centres, and multi-chelating for Ge centres), was obtained by solvothermal synthesis using Hheda as a reducing agent for V^V (Table 2). The pale purple colour of this low-nuclearity compound was shown to be due to the absorption bands at 2.18 eV (568 nm) and 1.46 eV (856 nm) assigned to d-d transitions of the vanadium ions in quasi-octahedral coordination. The central fragment of [V₆Ge₅O₂₁(heda)₆]·3H₂O is a C₂ symmetrical GePOV, which is not structurally related to the $\{V_{18}O_{42}\}$ archetype like the abovementioned "fully-reduced" alkoxoGePOV $[H_2V_9^{IV}Ge_6O_{26}(L)_6]^{2-103}$ and the mixed-valent $[V_2^{IV}V_{12}^VGeO_{40}]^{8-}$ polyoxoanion. The structure of the neutral [V₆Ge₅O₂₁(heda)₆] compound is composed of two {VO₅} square pyramids, two {VO₆} octahedra and two {VO₅N} octahedra and involves three tetrahedral {GeO₄} and two octahedral {GeO₄N₂} moieties. According to the optical diffuse reflectance spectrum, [V₆Ge₅O₂₁(heda)₆]·3H₂O possesses an energy gap of 2.88 eV.

2.3.5 TMC-supported GePOVs

Zinc- and cadmium-GePOV hybrids. Yang and coworkers succeeded in the hydrothermal synthesis of a series of the

Fig. 10 Schematic design of the TMC-supported, "fully-reduced" hybrid polyoxoanion $[Cd_2(en)_2V_{12}^{1/2}O_{40}(GeOH)_8]^{4-}$ (right). This tetraanion is formed when two $(VO)^{2+}$ caps situated between the $\{Ge_2O_7\}$ groups in α - $[V_1^{1/4}O_{42}(GeOH)_8]^{4-}$ (left) are replaced with two $[Cd(en)]^{2+}$ fragments. Encapsulated water molecule and hydrogen atoms are not shown. Colour code: Ge, green; N, blue; O, red; $V^{IV}O_x$, sky-blue polyhedra; Cd, brown.

inorganic-organic hybrid materials [Cd(en)₂]₂[Cd₂(en)₂V₁₂O₄₀- $(GeOH)_8(H_2O)$]· $6H_2O$ (en = ethylenediamine = $C_2H_8N_2$), $[Zn_2(enMe)_3][Zn(enMe)]_2[V_{15}Ge_6O_{48}(H_2O)][Zn(enMe)_2(H_2O)]_2 \cdot 3H_2O$ (enMe = 1,2-diaminopropane), and $[Cd_3(dien)_2(Hdien)_2(H_2O)_2]$ - $[V_{16}Ge_4O_{42}(OH)_4(H_2O)]\cdot 2H_2O$ (Table 2). The adjustment of the pH value to the alkaline media (pH = 8.8-12.5) was crucial for isolation of these products. Their crystal structures show the "fullyreduced" polyoxoanions $[Cd_2(en)_2V_{12}^{iN}O_{40}(GeOH)_8(H_2O)]^{4-}$ (Fig. 10), $[H_2O@V_{15}^{IV}Ge_6O_{48}]^{12-}$ and $[H_2O@V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ (Fig. 8a) which are interconnected by transition metal cations $[Cd(en)_2]^{2+}$, $[Zn(enMe)]^{2+}/[Zn_2(enMe)_3]^{4+} \ \ and \ \ [Cd_3(\mu\text{-dien})_2(Hdien)_2(H_2O)_2]^{8+}$ respectively. These bind to the GePOV building blocks through the O atoms of {VO₅} square pyramids or the apical O atoms of {GeO₄} tetrahedra, thus forming Cd-O_{term}-V and Zn-O_{term}-Ge connectivities. Interestingly, the [Cd₂(en)₂V^{IV}₁₂O₄₀(GeOH)₈]⁴⁻ polyoxoanion illustrated in Fig. 10 incorporates two [Cd(en)]²⁺ units in the dilacunary-type $\alpha - [V_{12}^{IV}O_{40}(GeOH)_8]^{8-}$ backbones. The 1D sinusoidal chains established for [Cd(en)₂]₂[Cd₂(en)₂- $V_{12}O_{40}(GeOH)_8(H_2O)$]·6H₂O with $d_{V ext{--}V} = 2.86-3.03 \text{ Å}$ are additionally arranged through N-H···O and O-H···O hydrogen bonds to afford a 3D supramolecular framework with pseudocircular channels. The interchain distance was found to be ca. 10.65 Å. The $\{V_{15}\}$ - and $\{V_{16}\}$ -nuclearity GePOVs are the representatives of the class of polynuclear molecular mixedmetal oxides with the general formula $[V_{18-z}Ge_{2z}O_{42}(O,OH)_{2z}]$ (z = 2, 3) and show interesting structural relationships to other reported GePOVs and SiPOVs. Whereas $[V_{15}^{IV}Ge_6O_{48}]^{12-}$ and $[V_{15}^{IV}\mathrm{Si}_6\mathrm{O}_{42}(\mathrm{OH})_6]^{6-}$ (Fig. 6c) are isostructural analogues, the polyoxoanions $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ (Fig. 8a) and $[V_{16}^{IV}Si_4O_{46}]^{12-}$ (Fig. 6a) are conformational isomers differing by the geometrical positions of the handle-like $\{E_2O_7\}$ groups in the POV structure. While the $[Cd_2(en)_2V_{12}^{IV}O_{40}(GeOH)_8(H_2O)]^{4-}$ and $[V_{15}^{IV}Ge_6O_{48}]^{12-}$ polyoxoanions exhibit strong antiferromagnetic coupling, the magnetic behaviour of the $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ polyoxoanion was reported to exhibit intramolecular ferrimagnetic coupling, which is rare for such POMs.111

Tetra-Cd^{II}-substituted GePOVs were also reported. Two isomorphic, mixed-valent compounds with the general formula $[\{CdL\}_4V_{10}Ge_8O_{46}(H_2O)[V(H_2O)_2]_4(GeO_2)_4]\cdot 8H_2O$ (L = en, enMe) were synthesised under hydrothermal conditions using the weak acids H_3BO_3 or $H_2C_2O_4\cdot 2H_2O$ and the alkaline media at

Chem Soc Rev

pH = 9.7-10 (Table 2). 112 Their crystal structures exhibit 3D 10connected, inorganic-organic frameworks (point-symbol of 3¹²·4²⁸·5⁵ for the bct topology) which are constructed from the D_{4b} -symmetric, "fully-reduced" $[\{CdR\}_4V_{10}^{IV}Ge_8O_{46}(H_2O)]^{12-}$ hybrid polyoxoanions covalently connected to each other via the planar, "highly-reduced" $[V_4^{III}O_2(H_2O)_8]^{8+}$ units $(d_{V\cdots V} = 2.47 \text{ Å})$ and the bridging {GeO₄} tetrahedra (an unusual situation in POM chemistry, however observed for {SiO₄} units in Cs_{10.5}[(V₁₆O₄₀)- $(V_{1.5}Si_{4.5}O_{10})]\cdot 3.5H_2O^{95}$). The Cd²⁺ ions are incorporated into the backbones of the tetralacunary β-isomeric GePOV building block composed of ten {VO₅} square pyramids and thus display trigonal prismatic geometries (CdO₄N₂), similarly to the "fully-reduced" $\left[\mathrm{Cd}_{2}(\mathrm{en})_{2}\mathrm{V}_{12}^{\mathrm{IV}}\mathrm{O}_{40}(\mathrm{GeOH})_{8}\right]^{4-}$ hybrid polyoxoanion (Fig. 10). An attempt to replace these Cd2+ ions coordinated in a circular {{CdR}₄Ge₈O₂₈}¹⁶⁻ constituent of the dodecaanion by Mn²⁺, Fe²⁺, Co²⁺, Ni²⁺ or Zn²⁺ under applied reaction conditions (Table 2) has failed. This type of CdII-substituted GePOVs exhibit antiferromagnetic properties.

Cobalt-GePOV hybrids. Further two {V₁₆Ge₄}-type polyoxoanions now supported by bridging Co^{II} complexes were described by Xu, Hu and colleagues. 113 The compounds [Co(enMe)₂]₃- $[Co_2(enMe)_4][V_{16}Ge_4O_{44}(OH)_2(H_2O)]\cdot 5H_2O$ and $[Co_2(en)_3][Co(en)_2]_2 [Co(en)_2(H_2O)][V_{16}Ge_4O_{44}(OH)_2(H_2O)]\cdot 10.5H_2O$ with extended 3D frameworks in their crystal structures were obtained hydrothermally in alkaline solutions at pH = 10.2-10.8 (Table 2). The structures of these compounds consist of the "fully-reduced" $[H_2O@V_{16}^{IV}Ge_4O_{44}(OH)_2]^{10-}$ anions charge-balanced by Co^{2+} centred amine complexes and exhibit different structural topologies. Whereas $[Co(enMe)_2]_3[Co_2(enMe)_4][V_{16}Ge_4O_{44}(OH)_2(H_2O)]\cdot 5H_2O$ adopts a NaCl-type network composed of different TMC linkers and $[H_2O@V_{16}^{IV}Ge_4O_{44}(OH)_2]^{10-}$ polyoxoanions as 6-connected nodes, $[Co_2(en)_3][Co(en)_2]_2[Co(en)_2(H_2O)][V_{16}Ge_4O_{44}(OH)_2(H_2O)]$ 10.5H₂O is characterised by a (4,6)-connected network [Schläfli symbol $(4^6 \cdot 6^7 \cdot 8^2)_2 (4^2 \cdot 6^4)$], which was previously not known for heteroPOVs. Two types of relatively short interatomic distances $d_{V...V} = 2.80-3.07 \text{ Å}$ and $d_{Co...V} = 3.38-3.60 \text{ Å}$ were observed. According to the variable temperature susceptibility measurements, these two compounds feature ferrimagnetic characteristics.

Manganese- and nickel-GePOV hybrids. The solvothermally prepared $[\{Mn(tren)(H_2tren)\}\{Mn(tren)\}_4V_{15}Ge_6O_{48}(H_2O)_{0.5}]\cdot tren\cdot 2H_2O$ and $[\{Ni(tren)\}_4(H_2tren)_2V_{15}Ge_6O_{48}(H_2O)]\cdot 2H_2O$ compounds are characterised by the {V₁₅Ge₆}-type polyoxoanions which could be expanded into the high-nuclearity GePOV networks. 114 The structural analysis of these charge-neutral helical 1D strands and 2D layers revealed different coordination environments of unique, in situ-formed MnII and NiII complexes as well as different interconnection modes of the spherical, "fully-reduced" [V₁₅^{IV}Ge₆O₄₈]¹²⁻ polyoxoanions with encapsulated water guest molecules. Interestingly, the reaction conditions were very similar in each case except the nature and amount of transition metal starting materials (Table 2). The central $\{V_{15}Ge_6O_{48}(H_2O)_{0.5}\}$ structural motif of [{Mn(tren)(H₂tren)}{Mn(tren)}₄V₁₅Ge₆O₄₈-(H₂O)_{0.5}] tren·2H₂O, which is stable up to 350 °C, is coordinated by five crystallographically independent Mn^{II} complexes via

Mn-O(-V/Ge) bonds. The compound exhibits a three layer solid-state structure, which is composed of the following subfragments: (i) six corner- and edge-sharing square pyramidal $\{VO_5\}$ units and a $[MnO(H_2tren)(tren)]^{2+}$ complex; (ii) a $\{V_3Ge_6O_{28}\}$ ring, [Mn(tren)]²⁺ and [Mn₂O₂(tren)₂]⁴⁺ complexes; (iii) six cornerand edge-sharing {VO₅} square pyramids. The crystal structure of this GePOV-based inorganic-organic hybrid displays [Mn(tren)]2+ and [Mn(tren)(H2tren)]4+ moieties and a rare dinuclear $[Mn_2O_2(tren)_2]^{4+}$ fragment that bridges two terminal O atoms of the handle-like $\{Ge_2O_7\}$ groups from the adjacent GePOVs. In contrast to $[Mn_2O_2(tren)_2]^{4+}$, the $[Mn(tren)(H_2tren)]^{4+}$ complex is bound to the surface of the GePOV shell via a terminal O atom of a pyramidal {VO₅} unit. The crystal structure of $[{Ni(tren)}_4(H_2tren)_2V_{15}Ge_6O_{48}(H_2O)]\cdot 2H_2O$ comprises binuclear [{Ni(tren)}(H₂tren){Ni(tren)}]⁶⁺ complexes, which coordinate only to the {VO₅} square pyramids of the polyoxoanion and bridge the neighbouring {V₁₅Ge₆O₄₈} building blocks through V=O-Ni bonds in a manner to allow for the formation of "rhombic windows" in which crystal water molecules reside. The magnetochemical analysis of these two compounds indicated that neither Mn^{II} nor Ni^{II} ions affect the spin structure of the [V₁₅Ge₆O₄₈]¹²⁻ polyoxoanion showing the typical "V₆-V₃-V₆" layer structure with V···V distances ranging from 2.84 to 3.10 Å. The compounds feature weak antiferromagnetic interactions between the spin-1/2 vanadyl ${VO}_{2}^{2+}$ moieties of the ${V_{15}Ge_6O_{48}}$ building block and the adjoined Mn^{II} or Ni^{II} complexes.

2.3.6 Corollary for GePOVs. "Fully-reduced" alkoxoGePOV and TMC-supported GePOVs as well as a number of structurally isolated "fully-reduced" and mixed-valent GePOVs have been published so far. These polyoxoanions include tetrahedral Ge^{IV} heteroatoms, with only one example of octahedral Ge^{IV} inclusion and are characterised by a range of different (approximate) symmetries, e.g. D_{3h} for $[H_2V_9^{IV}Ge_6O_{26}(L)_6]^{2-}$, D_{2d} for $[(en)_2Cd_2V_{12}^{IV}O_{40}(GeOH)_8]^{4-}$ and $[V_{14}^{IV}O_{44}(GeOH)_8]^{8-}$, $D_{4\mathrm{h}}$ for $[V_2^{\mathrm{IV}}V_{12}^{\mathrm{V}}\mathrm{GeO}_{40}]^{8-}$ and $[\{\mathrm{CdR}\}_4V_{10}^{\mathrm{IV}}\mathrm{Ge}_8\mathrm{O}_{46}(\mathrm{H}_2\mathrm{O})]^{12-}$, S_4 for $\alpha - [V_{14}^{IV}Ge_8O_{50}]^{12-}$ and $\alpha - [V_{14}^{IV}Ge_8O_{42}S_8]^{12-}$, D_3 for $[V_{15}^{IV}Ge_6O_{48}]^{12-}$ and C_2 for $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$. Similarly to the SiPOV building blocks, the GePOVs were connected by TMC bridging groups to afford network structures of different dimensionality. Unlike the SiPOVs, the GePOVs were found to incorporate secondary TMCs in the backbones of the polyoxoanion shells (Fig. 10). Furthermore, unusual handle-like {Ge₂O₅S₂} groups were identified in the $[V_{14}^{IV}Ge_8O_{42}S_8]^{12-\ 99}$ (Fig. 8c) and $[H_2O@V_{15}^{IV}Ge_6O_{42}S_6]^{12-\ 102}$ polyoxoanions. The {V₁₆Ge₄}-type GePOVs were found to exhibit ferrimagnetic properties. 110,113

3. Group 15 (As, Sb) elementfunctionalised POVs

3.1 Preview

One of the key differences between the SiPOVs/GePOVs and the polyoxovanadatoarsenates (AsPOVs)/polyoxovanadatoantimonates (SbPOVs) is the absence of the effective electron lone pairs at Si^{IV}/Ge^{IV} in the former and their presence at As^{III}/Sb^{III} in the latter. Note that these electron lone pairs provide different

Review Article Chem Soc Rev

steric hindrances around the E and terminal oxygen atoms (O_{term}) in the heteroPOVs, thus influencing the reactivity of the E sites towards the TMC complexes and organic ligands. In comparison to SiPOVs and GePOVs, the chemistry of Sb- and, especially, As-incorporating POVs is more widely developed and resulted in a variety of discrete and multidimensional structures with interesting chemical and physical properties. The AsPOVs and SbPOVs are frequently prepared under hydrothermal or solvothermal conditions (Tables 3 and 4). The AsPOVs known thus far are characterised by both the low-nuclearity and high-nuclearity assemblies, which are classified as V_5 , V_6 , V_{10} , V_{12} , V_{13} , V_{14} , V_{15} , V_{16} , V_{20} and V_{24} series. SbPOVs show assemblies with nuclearity V_{14} , V_{15} , V_{16} and V_{20} . Some of their most common skeletons are shown in Fig. 11.

As vanadium precursors for the synthesis of the AsPOVs (Table 3) and SbPOVs (Table 4), V2O5 and NH4VO3 were extensively used, whilst NaVO3, VOSO4 and vanadium halides were employed less frequently. The POV structures decorated with handle-like $\{E_2O_5\}$ groups (E = As, Sb) are typically viewed as being derived from the {V18O42} archetype, with only some exceptions which are discussed in Section 3. In contrast to the Si^{IV} and Ge^{IV} atoms displaying tetrahedral {EO₄} geometries in the heteroPOV structures, the heavier group 15 elements, As and Sb, usually adopt trigonal pyramidal {EO₃} geometries and show the formal oxidation state +3; however, very rarely tetrahedral {AsO₄}³⁻ units and arsenic atoms in the formal oxidation state +5 were also identified. The As-O bonds ($d_{As-O} = 1.52-2.02 \text{ Å}$) are usually longer than the terminal V=O bonds ($d_{V=O} = 1.52-1.68 \text{ Å}$), but shorter than the bridging V–O bonds ($d_{V-O} = 1.72-2.33$ Å). The Sb–O bonds $(d_{Sb-O} = 1.90-2.04 \text{ Å})$ fall in the range of V-O bond lengths, but these are remarkably longer than the V=O bonds.

3.2 Polyoxovanadatoarsenates (AsPOVs)

3.2.1 AsPOVs with a low proportion of As^V

AsPOVs with the encapsulated AsO₄ units. In the early 1990s Müller, Gatteschi and colleagues described the synthesis and magnetic properties of the compound K₆[H₃KV₁₂As₃O₃₉(AsO₄)]-8H₂O exhibiting electron delocalisation effects. 115 The central constituent of this compound obtained upon reduction of an aqueous solution of potassium metavanadate KVO3 is the mixedvalent $[H_3KV_4^{IV}V_8^{V}As_3^{V}O_{39}(As^{V}O_4)]^{6-}$ polyoxoanion with approximate C_3 symmetry (Table 3). The structure of this AsPOV consists of nine {VO₆} octahedra, three {VO₄} tetrahedra, and four {As^VO₄} tetrahedra. One of these arsenate units {AsO₄}³⁻ is covalently enclosed within the AsPOV shell (Fig. 12). The terminal O atoms of three other, peripheral {AsVO₄} groups are protonated. A potassium ion caps the monolacunary [H₃V₁₂As₃O₃₉(AsO₄)]⁷⁻ polyoxoanion. The electron population in this AsPOV was confirmed by bond valence sum analysis and manganometric titration. In the structure, K₆[H₃KV₁₂As₃O₃₉(AsO₄)]·8H₂O displays zigzag chains in which the neighbouring [H₃KV₄^{IV}V₈^VAs₃^VO₃₉(As^VO₄)]⁶ polyoxoanions are linked through the $K \cdots O_{term}$ -V interactions.

Another potassium-containing compound, $K_3[H_{12}V_{12}O_{36}^-(AsO)_2(AsO_4)]\cdot 12H_2O$ (Table 3), displays a structure that can be formally viewed as α -Keggin-type $\{V_6^{IV}V_6^VO_{36}(As^VO_4)\}$ core with two of its six tetragonal $\{V_4O_4\}$ faces additionally capped by two

{As^VO} groups. ¹¹⁶ As in the case of $[H_3KV_4^{IV}V_8^{V}As_3^{V}O_{39}(As^{V}O_4)]^{6-}$, the tetrahedral {AsO₄}³⁻ unit is enclosed within the {V₁₂O₃₆} cage of the mixed-valent $[H_{12}V_6^{IV}V_6^{V}O_{36}(AsO)_2(AsO_4)]^{3-}$ polyoxoanion. The twelve O sites of this AsPOV are protonated and three K^+ cations then compensate the -3 net charge of the polyoxoanion. In the crystal structure, each of these K^+ cations is coordinated by four water molecules and is involved in bonding to four adjoined $[H_{12}V_{12}O_{36}(AsO)_2(AsO_4)]^{3-}$ polyoxoanions through (weak) K–O bonds.

Another type of a bicapped Keggin structure with two capping $\{V^VO\}$ groups instead of two $\{As^VO\}$ ones was found for the fully-oxidised $[H_6V_{12}^VO_{36}(V^VO)_2(AsO_4)]^{3-}$ polyoxoanion isolated as $(NEt_4)_3[H_6V_{12}AsO_{40}(VO)_2]\cdot 20H_2O$ (Table 3). 117 The α -Keggin core of this AsPOV consists of twelve $\{VO_6\}$ octahedra and the covalently enclosed, central $\{AsO_4\}$ tetrahedron whose O atoms are shared by four $\{V_3O_{13}\}$ groups of edge-sharing octahedra.

Neutral AsPOV with the capping AsO₄ units. The tetrahedral $\{AsO_4\}^{3-}$ units capping tetragonal vanadium oxide faces were observed in hydrothermally synthesised $[V_8^{IV}V_2^VAs_2^VO_{26}(H_2O)]\cdot 8H_2O$ (Table 3). Its crystal structure shows an extended 3D network in which the neutral, mixed-valent POVs are joined through $\{AsO_4\}$ bridging groups. Notably, this compound exhibited catalytic activity for phenol hydroxylation, offering high selectivity to hydroquinone.

3.2.2 {V₁₂As₈}-type polyoxoanions

Discrete mixed-valent AsPOVs. The first polyoxoanions from this class of AsPOVs were presented by Müller and co-workers, in 1991. The formate-enclosing β -[HCO₂@V₆^{IV}V₆VAs₈O₄₀]³⁻ and β-[HCO₂@V₈V₄V₄As₈O₄₀]⁵⁻ components of the mixed-valent compounds (NHEt₃)₂(NH₂Me₂)[V₁₂As₈O₄₀(HCO₂)]·2H₂O and $Na_5[V_{12}As_8O_{40}(HCO_2)]\cdot 18H_2O$ (Table 3), respectively, display different electron populations and different types of spin-spin interactions, albeit their AsPOV shells with encapsulated formiate ions are isostructural and possess D_{4h} symmetries. The strength of the spin-spin coupling in these polyoxoanions composed of four handle-like {As2O5} groups and twelve {VO5} square pyramids was shown to be influenced by the number of V^{IV} centres: the larger number of these centres, the stronger coupling. Their magnetic properties were additionally studied by Gatteschi and colleagues. 120 Although the $[HCO_2@V_6^{IV}V_6^VAs_8O_{40}]^{3-}$ and [HCO₂@V₈^{IV}V₄^VAs₈O₄₀]⁵⁻ polyoxoanions are isonuclear, they exhibit dissimilar magnetic properties due to the different AsPOV spin topologies and delocalisation effects of the d1-VIV electrons. According to the magnetic susceptibility data, the AsPOV trianion is characterised by ferromagnetic coupling between delocalised and localised VIV ions and the AsPOV pentaanion features a singlet (S = 0) ground state because of strongly coupled, delocalised V^{IV} ions. Furthermore, it was stated that field-dependent relaxation effects may influence the EPR spectra (at X-band) of these dodecanuclear species.

About 10 years later, Güdel and colleagues conducted an INS study for three new, but related dodecanuclear β -AsPOVs isolated as Na₄[V₈^{IV}V₄^VAs₈O₄₀(H₂O)]·23H₂O, the deuterated derivative Na₄[V₈^{IV}V₄^VAs₈O₄₀(D₂O)]·16.5D₂O, and (NHEt₃)₄[V₈^{IV}V₄^VAs₈O₄₀-(H₂O)]·H₂O (Table 3). ¹²¹ The goal of the study was to gain insights into magnetic exchange interactions in these mixed-valent spin

 Table 3
 Selected details of synthesis and characterisation of AsPOV-based compounds

Fig. 11 Vanadium skeletons found in some "fully-reduced" AsPOVs and SbPOVs.

Fig. 12 Polyhedral representation of the mixed-valent [H₃KV₄^VV₈As₃^VO₃₉-(As^VO₄)]⁶⁻ polyoxoanion resembling the ε-Keggin-type POM archetype. Hydrogen atoms are not shown. Colour code: As^V, rose; {As^VO₄}, rose tetrahedron in the centre; O, red; V^V/V^{IV}O_x, dark-grey polyhedra; K, turquoise.

structures possessing two outer $(d_{V\cdots V}=3.410-3.450~\text{Å})$ and one inner (or central) V_4 squares $(d_{V\cdots V}=5.26-5.31~\text{Å})$ bridged by $[As_2O_5]^{4-}$ groups. The magnetic transitions (up to four) between the S=0 ground state of the $\{V_8^{IV}V_4^VAs_8\}$ building block and its excited states were identified by INS. By this study, the authors confirmed "the essential correctness of an earlier model developed on the basis of magnetic and EPR measurements" that were performed for the aforementioned $[HCO_2@V_8^{IV}V_4^VAs_8O_{40}]^{5-}$ polyoxoanion.

The family of the $\{V_8^{IV}V_4^VAs_8\}$ -type compounds $^{119-121}$ was extended by the compound $(NH_4)_4[V_{12}As_8O_{40}(H_2O)]\cdot 4H_2O$ obtained under solvothermal conditions using the mixtures of ethyl ether/ H_2O or ethanol/ H_2O as reducing agents (Table 3). 122 The building block of this compound is the mixed-valent β - $[H_2O@V_8^{IV}V_4^VAs_8O_{40}]^{4-}$ polyoxoanion with the shortest interatomic $V\cdots V$ distance of 3.02 Å and a diameter of ca. 11 Å. In the crystal of $(NH_4)_4[V_{12}As_8O_{40}(H_2O)]\cdot 4H_2O$, the AsPOVs are joined by weak intercluster $As\cdots O$ interactions with the shortest $As\cdots O$ distance of 3.05 Å. The H_2O molecules and NH_4 countercations reside in the voids between the polyoxoanions. The strong hydrogen bonds formed between the NH_4 ions and the terminal O atoms of the $[H_2O@V_8^{IV}V_4^VAs_8O_{40}]^{4-}$ polyoxoanion result in the formation of a 3D network. $(NH_4)_4[V_{12}As_8O_{40}(H_2O)]\cdot 4H_2O$ exhibits a distinct solubility in H_2O , MeOH and DMF and shows an optical energy gap of 2.80 eV.

Zinc–AsPOV hybrids. A number of hydrothermally synthesised compounds based on the bis-transition metal-substituted AsPOVs of the type $\{M_2V_{12}As_8O_{40}\}$, which exhibit antiferromagnetic exchange interactions, were described. These hybrid polyoxoanions are formally derived from the α - $\{V_{14}As_8O_{42}\}$ polyoxoanion (discussed in Section 3.2.4) in which two $\{VO\}^{2^+}$ caps situated between the mutually opposite $\{As_2O_5\}$ groups are replaced by two M^{2^+} ions.

Fig. 13 (a) Polyhedral representation of $[\{Zn(enMe)_2\}_2(enMe)_2\{Zn_2V_{12}As_8O_{40}(H_2O)\}]$ containing the "fully-reduced" $[H_2O@Zn_2V_{12}^{V}As_8O_{40}]^{4-}$ hybrid polyoxoanion. (b) A segment of the polymeric solid-state structure of $[\{Zn(en)_3\}_2\{Zn_2V_{12}As_8O_{40}(H_2O)\}]\cdot 4H_2O\cdot 0.25$ bipy. (c) A segment of the polymeric solid-state structure of $[Zn_2(en)_3]\{Zn(en)_2\}\{(bpe)HZn_2V_{12}As_8O_{40}(H_2O)\}_2]\cdot 7H_2O$. Hydrogen atoms are omitted for clarity. Colour code: C, grey; N, blue; As, rose; O, red; $V^{IV}O_{X_1}$ sky-blue polyhedra; Zn, dark green.

This kind of incorporation of transition metal cations into the backbones of dilacunary α-heteroPOV shells was also observed in the case of the aforementioned "fully-reduced" [Cd2(en)2- $V_{12}^{IV}O_{40}(GeOH)_8]^{4-}$ polyoxoanion¹¹⁰ (Fig. 10). One of these M₂-decorated AsPOVs was found in [{Zn(enMe)₂}₂(enMe)₂- ${\rm Zn_2V_{12}As_8O_{40}(H_2O)} \cdot {\rm H_2O^{123}}$ (Table 3). The main structural motif of this hybrid compound is a dilacunary {V12As8O40} shell functionalised with two $[Zn_2(enMe)_3]^{2+}$ complexes via Zn-O bonds (Fig. 13a). Each of two [Zn(enMe)₂]²⁺ moieties is linked to the $[H_2O@Zn_2V_{12}^{IV}As_8O_{40}]^{4-}$ polyoxoanion by the enMe residuals through Zn-N bonds. Strong hydrogen bonds contribute to the formation of a 3D supramolecular array. The crystal structure of another similar compound {[Zn(dien)]2(dien)2[Zn2V12As8O40-(0.5H₂O)]}₂·6H₂O¹²⁴ (Table 3) displays two crystallographically independent $[0.5H_2O@Zn_2V_{12}^{IV}As_8O_{40}]^{4-}$ polyoxoanions each of which is decorated with two [Zn(dien)]2+ complexes through dien connecting groups. The two resulting [Zn(dien)]₂(dien)₂-[Zn₂V₁₂As₈O₄₀(0.5H₂O)] constituents are linked to form a dimer by a weak Zn-O bond.

The compound [Zn(en)₂]₂[Zn₂(bpe)₂V₁₂As₈O₄₀(H₂O)] (Table 3) is composed of the [(bpe)₂Zn₂V^{IV}₁₂As₈O₄₀(H₂O)]⁴⁻ polyoxoanion [bpe = 1,2-bis(4-pyridyl)ethylene] and two [Zn(en)₂]²⁺ countercations. ¹²⁵ This hybrid polyoxoanion based on the α -AsPOV is constructed from twelve {VO₅} square pyramids, two square-pyramidal {ZnNO₄} units and four handle-like {As₂O₅} groups.

Review Article Chem Soc Rev

The Zn²⁺ ions introduced into the backbones of the AsPOV building block are coordinated by the bpe ligands through Zn-N bonds. The two terminal O atoms on the opposite sides of the eight-membered, {VO₅}-composed ring of the [(bpe)₂Zn₂V₁₂^{IV} $As_8O_{40}(H_2O)^{4-}$ polyoxoanion are covalently connected to the [Zn(en)₂]²⁺ complexes through Zn–O bonds. This compound with two structurally exposed pendant pyridyl rings of the bpe ligand could probably be of relevance for surface deposition studies.

The compounds $[Zn(enMe)_2]_2[(4,4'-bipy)Zn_2V_{12}As_8O_{40}(H_2O)],$ $[Zn(en)_2(H_2O)][Zn(en)_2(4,4'-bipy)Zn_2V_{12}As_8O_{40}(H_2O)]\cdot 3H_2O, [\{Zn(en)_3\}_{2^{-1}}]\cdot (H_2O)]\cdot 3H_2O, [\{Zn(en)_3\}_{2^{-1}}]\cdot (H_2O)]\cdot (H_2O)$ ${Zn_2V_{12}As_8O_{40}(H_2O)}$ - ${4H_2O\cdot 0.25bipy}$ and ${Zn_2(en)_5}$ - ${Zn(en)_2}$ - $\{(bpe)HZn_2V_{12}As_8O_{40}(H_2O)\}_2\}$. $7H_2O$ composed of zinc(II) amine complexes and the "fully-reduced", bis-zinc-substituted α-isomeric AsPOVs with compositions $[H_2O@Zn_2V_{12}^{IV}As_8O_{40}]^{4-}$ and its protonated $[H_2O@HZn_2V_{12}^{IV}As_8O_{40}]^{3-}$ form were reported. ¹²⁶ Crystalline samples of these inorganic-organic hybrid materials could only be obtained in alkaline solutions when the pH value was adjusted between 8 and 10, which allowed deprotonation of N-donor ligands and their easier coordination to the Zn²⁺ ions (Table 3). The different structural features of the organic ligands captured by the secondary Zn²⁺ ions were shown to have an effect on the formation and construction of the above compounds, thus resulting in the polyoxoanions that are packed in linear or staggered arrangements in the solid state. The crystal structure of [Zn(enMe)₂]₂-[(4,4'-bipy)Zn₂V₁₂As₈O₄₀(H₂O)] exhibits linear chains of the [(4,4'-bipy)Zn₂V₁₂As₈O₄₀(H₂O)]⁴⁻ polyoxoanions charge-balanced by discrete [Zn(enMe)₂]²⁺ complexes occupying the interchain regions. The "fully-reduced" [H₂O@Zn₂V₁₂^{IV}As₈O₄₀]⁴⁻ polyoxoanions are linked by bridging 4,4'-bipy ligands through Zn-N bonds. It was also found that [Zn(enMe)₂]₂[(4,4'-bipy)Zn₂V₁₂- $As_8O_{40}(H_2O)$] is electrocatalytically active in the reduction and oxidation of H₂O₂ and NO₂ using bulk-modified carbon paste electrodes. The crystal structure of [Zn(en)₂(H₂O)][Zn(en)₂(4,4'bipy)Zn₂V₁₂As₈O₄₀(H₂O)]·3H₂O displays 1D winding chains of the $[(4,4'-bipy)Zn_2V_{12}As_8O_{40}(H_2O)]^{4-}$ hybrid clusters functionalised with the [Zn(en)2]2+ complexes through Zn-O bonds; [Zn(en)₂(H₂O)]²⁺ complexes act as countercations. Similarly to the previous compound, the 4,4'-bipy ligands bridge the {Zn₂V₁₂As₈O₄₀} building blocks through Zn-N bonds. The Zn²⁺ cations are incorporated into the dilacunary-type AsPOV shell through Zn-O bonds. The extensive hydrogen bonding in the crystal lattice results in the formation of a 3D supramolecular architecture. The crystal structure of [{Zn(en)₃}₂{Zn₂V₁₂As₈O₄₀-(H₂O)}]-4H₂O-0.25bipy is described as an eight-shaped chiral helical chain, where the "fully-reduced" [H₂O@Zn₂V^{IV}₁₂As₈O₄₀]⁴⁻ hybrid polyoxoanions are covalently bridged by the [Zn(en)₃]²⁺ complexes through Zn-N and Zn-O bonds, as shown in Fig. 13b. In contrast to the above-mentioned compounds, [Zn₂(en)₅][{Zn(en)₂}- $\{(bpe)HZn_2V_{12}As_8O_{40}(H_2O)\}_2$]- $7H_2O$ has a 2D layer structure with nanosized inner 1D rectangular cavities of 33.7 \times 14.7 Å. These cavities are occupied by the lattice H₂O molecules and [Zn₂(en)₅]⁴⁺ cations. The connectivity of the "fully-reduced" [H2O@HZn2- $V_{12}^{IV}As_8O_{40}]^{3-}$ building blocks through the $[Zn(en)_2]^{2+}$ complexes and the bidentate bpe ligands (Fig. 13c), yielding a single-stranded (right- and left-handed) helical chain, resembles that found in the crystal structure of $[Zn(en)_2]_2[Zn_2(bpe)_2V_{12}As_8O_{40}(H_2O)]^{125}$

Cadmium-AsPOV hybrids. Cd2+-en complexes were incorporated into the dilacunary β-{V₁₂As₈O₄₀}-type structure through Cd-O bonds to form the "fully-reduced" [Cd₂(en)₂V₁₂^{IV}As₈O₄₀]⁴⁻ polyoxoanion, which is charge-balanced by two [Cd(en)₂]²⁺ complexes. 127 This compound with composition [Cd(en)₂]₂-[Cd₂(en)₂V₁₂As₈O₄₀] was prepared under hydrothermal conditions (Table 3) and displays a 1D chain structure where neighbouring $[Cd_2(en)_2V_{12}^{IV}As_8O_{40}]^{4-}$ polyoxoanions are doubly bridged via [Cd(en)₂]²⁺ groups. The interface between these hybrid building blocks is characterised by eight-membered rings involving Cd²⁺ ions from the TMC linkers and terminal and bridging O atoms from the connected polyoxoanions. Hydrogen bonds extend the 1D chains into a 3D supramolecular network.

Two other compounds, [Cd(enMe)₃]₂[(enMe)₂Cd₂V₁₂As₈O₄₀- $(0.5H_2O)$] $\cdot 5.5H_2O$ and $[Cd(enMe)_2]_2[Cd_2(enMe)_2V_{12}As_8O_{40}(0.5H_2O)]_1$ were found to contain α- and β-isomeric [Cd₂(enMe)₂V₁₂^{IV} $As_8O_{40}(0.5H_2O)$ ⁴⁻ constituents, respectively (Table 3). Whereas the former compound can be viewed as an isolated (0D) inorganic-organic hybrid, the latter compound shows an infinite, 1D linear chain structure due to the [Cd(enMe)₂]²⁺ linkages and is furthermore isomorphic with the above-mentioned example $[Cd(en)_2]_2[Cd_2(en)_2V_{12}As_8O_{40}]$, ¹²⁷ with the exception of organic ligands coordinated to the Cd(II) centres and a half H2O molecule encapsulated by the polyoxoanion shell. In both compounds, the [Cd(enMe)]²⁺ complexes are attached to the AsPOV building blocks through Cd-O bonds. According to the diffuse reflectance UV-vis spectra, these compounds are characterized by optical energy gaps of ca. 2 eV.

3.2.3 {V₁₃As₈}-type polyoxoanions. The structural chemistry of this class of AsPOVs is still underdeveloped. To date, only the results reported by the groups of Yang, Xu and Wang are available. When a {VO}2+ group situated in between the {As2O5} groups in α -[V₁₄^{IV}As₈O₄₂]⁴⁻ (discussed in Section 3.2.4) is substituted by a divalent transition metal ion, a polyoxoanion of general composition [MIV₁₃AS₈O₄₁]⁴⁻ results. Thus, the cluster structure of this monosubstituted hybrid polyoxoanion is comparable to that of the aforementioned di-substituted [M₂V₁₂^{IV}As₈O₄₀]⁴⁻ polyoxoanion whose two {VO}2+ groups were exchanged by two divalent transition metal ions. The monolacunary {V₁₃As₈}nuclearity polyoxoanion was found to incorporate Zn²⁺ or Cd²⁺ ions as well as Ni²⁺ ion in the way presented above.

Zinc-AsPOV hybrid with a mixed V_{13}/V_{14} -structure. The compound $[Zn(2,2'-bipy)_3]_4[(ppz)\{\{Zn(tepa)\}_2ZnV_{13}As_8O_{41}(H_2O)\}_2]$ - $[V_{14}As_8O_{42}(0.5H_2O)]_2 \cdot 4H_2O$ (tepa = tetraethylenepentamine)¹²⁴ displays two different types of AsPOV constituents, namely the Zn-monosubstituted [H2O@ZnVINAS8O41]4- hybrid and the $[0.5H_2O@V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanion. The latter belongs to the class of {V14As8}-based compounds which are discussed in the next section. The ppz and tepa organic groups in this compound were in situ-formed from dien molecules used in the hydrothermal reaction (Table 3) and coordinate to the Zn²⁺ cations to result in the complexes $[Zn_2(ppz)]^{4+}$ and $[Zn(tepa)]^{2+}$. The $[Zn_2(ppz)]^{4+}$ unit bridges the two neighbouring α - $\{V_{13}As_8\}$ type AsPOVs, each of which is decorated with two [Zn(tepa)]²⁺ moieties through Zn-O bonds (Fig. 14a). The Zn2+ ions of the

Fig. 14 (a) The "fully-reduced" [$\{Zn(tepa)\}_2ZnV_{13}^{IV}As_8O_{41}(H_2O)\}$ building blocks connected via ppz ligand. (b) Polyhedral representation of the "fully-reduced" [(dien)CdV₁₃^{IV}As₈O₄₁(H₂O)]⁴⁻ hybrid polyoxoanion. (c) Polyhedral representation of the "fully-reduced" AsPOV dimer, {Cl@NiV₁₃^{IV}As₈O₄₁}₂, expanded by two octahedral [Ni(en)₂(H₂O)] fragments. Hydrogen atoms are omitted for clarity. Colour code: C, grey; N, blue; As, rose; O, red; Cl, lime; VIVOx, sky-blue polyhedra; Ni, bright green; Zn, dark green; Cd, brown.

[Zn₂(ppz)]⁴⁺ complex are integrated into the backbones of the $[{\rm Zn(tepa)}]_2 V_{13}^{\rm IV} {\rm As}_8 O_{41}({\rm H}_2 O)]^{2-}$ polyoxoanions to form $[{\rm Zn(tepa)}]_2$ ZnV₁₃As₈O₄₁(H₂O)], which are thus held together by ppz linkers *via* Zn-N bonds.

Cadmium-AsPOV hybrid. The "fully-reduced" [Cd(dien)V₁₃^{IV} $As_8O_{41}(H_2O)$ ⁴⁻ polyoxoanion (Fig. 14b) with the seven-coordinate Cd²⁺ ion was hydrothermally isolated as the compound [Cd(dien)₂]₂-[Cd(dien)V₁₃As₈O₄₁(H₂O)]·4H₂O (Table 3) showing strong antiferromagnetic interactions between the spin-1/2 vanadyl {VO}²⁺ moieties. 127 The other two hydrothermally prepared compounds $[Cd(en)_3][Cd(phen)(en)(H_2O)_2][Cd(en)V_{13}As_8O_{41}(H_2O)]\cdot 1.5H_2O$ and $[Cd(phen)_2(en)]_2[Cd(phen)V_{13}As_8O_{41}(H_2O)]\cdot 21H_2O\cdot phen$ (phen = 1,10-phenanthroline) feature the $[Cd(en)V_{13}^{IV}As_8O_{41}(H_2O)]^{4-}$ and $[Cd(phen)V_{13}^{IV}As_8O_{41}(H_2O)]^{4-}$ structures, where the Cd^{2+} ions coordinated by en and phen ligands are incorporated into the monolacunary α-type heteroPOV shells (Table 3). 125 In contrast to [Cd(dien)V₁₃As₈O₄₁(H₂O)]⁴⁻, the antiferromagnetic [Cd(en)V $_{13}^{IV}As_8O_{41}(H_2O)]^{4-}$ and $[Cd(phen)V_{13}^{IV}As_8O_{41}(H_2O)]^{4-}$ hybrid polyoxoanions comprise six-coordinate Cd2+ ions. In all these Cd-containing compounds, the $[Cd(dien)_2]^{2+}$, $[Cd(en)_3]^{2+}$, $[Cd(phen)(en)(H_2O)_2]^{2+}$, and $[Cd(phen)_2(en)]^{2+}$ complexes act as countercations.

Nickel-AsPOV hybrid. The "fully-reduced" [NiV₁₃^{IV}As₈O₄₁]⁴⁻ polyoxoanion with the Ni^{II}-filled monolacunary POV structure was isolated as the compound {[V₁₃As₈NiClO₄₁][Ni(en)₂(H₂O)]- $[Ni(en)_2]$ { $[Ni(en)_2(H_2O)_2]_{0.5}$ }· $4H_2O$ under hydrothermal reaction conditions (Table 3).129 Its crystal structure displays the hostguest [Cl@NiV₁₃^{IV}As₈O₄₁]⁵⁻ building blocks linked to each other through Ni-O-As bonds to form a dimeric assembly (Fig. 14c). The latter is further connected to the neighbouring dimer via bridging [Ni(en)₂]²⁺ complexes (corner-sharing Ni-O_{term}-V interactions) to result in an infinite 1D chain. The [Cl@NiV₁₃As₈O₄₁]⁵⁻ structure can be described as being constituted of thirteen squarepyramidal {VO5} moieties, four handle-like {As2O5} groups, and one square-pyramidal {ClNiO₄} entity with the strong Ni-Cl bonding interaction. The [Ni(en)₂(H₂O)]²⁺ and [Ni(en)₂]²⁺ complexes and a half [Ni(en)₂(H₂O)₂]²⁺ complex compensate the negative charge of this hybrid polyoxoanion. The compound exhibits antiferromagnetic properties.

3.2.4 $\{V_{14}As_8\}$ -type polyoxoanions

Discrete AsPOVs. This class of AsPOVs offers a large number of discrete polyoxoanions. In 1991, Müller and Döring reported a series of the "fully-reduced" α-AsPOVs with the general formula $[Y@V_{18-z}As_{2z}O_{42}]^{m-}$ where $Y = SO_3^{2-}$, SO_4^{2-} or H_2O and z = 4. These host-guest polyoxoanions were isolated as crystal solvent-free ammonium compounds (NH₄)₆[V₁₄As₈O₄₂(SO₃)], $(NH_4)_6[V_{14}As_8O_{42}(SO_4)]$ and $(NMe_4)_4[V_{14}As_8O_{42}(H_2O)]$. The authors highlighted that the V/As ratio, pH, and concentration of the reducing agents such as hydrazine sulfate (N₂H₆SO₄), hydrazine chloride (N₂H₅Cl) und sodium dithionite (Na₂S₂O₄) play an important role in the formation of these {Y@V₁₄As₈O₄₂}based compounds (Table 3) where the inner voids of the POV shells are occupied by statistically disordered small anionic or neutral guest (Y) species. Here, the D_{2d} -symmetrical AsPOVs are formally derived from the corresponding $[Y@V_{18}O_{42}]^{m-}$ structures by replacing four {VIVO}2+ vanadyl groups in the latter with four {As2IIIO}4+ moieties.

Also in 1991, Huan et al. presented a spherical $[(H_2O)_{0.5}(a)]$ $V_{14}^{IV}As_8O_{42}$ $\Big|^{4-}$ polyoxoanion that formed as the compound $(NMe_4)_4[V_{14}As_8O_{42}(H_2O)_{0.5}]$ under hydrothermal conditions (Table 3). 131 This "fully-reduced" AsPOV consists of fourteen condensed {VO₅} square pyramids and four handle-like {As₂O₅} groups and is characterised by a α-{V₁₄As₈O₄₂} shell of rhombicuboctahedral topology (Fig. 15a). This cluster shell encapsulates a disordered H₂O guest molecule. The β-isomer (Fig. 15b) encapsulating a statistically disordered ${\rm SO_4}^{2-}$ ion was identified in the hydrothermally prepared compound [NH2(CH2)4NH2]4- $[V_{14}As_8O_{42}(SO_4)]\cdot (HSO_4)_2$ (Table 3). ¹³² In contrast to the α -isomer with $D_{2\mathrm{d}}$ symmetry, the "fully-reduced" β -[SO₄@V^{IV}₁₄As₈O₄₂]⁶⁻ polyoxoanion exhibits D_{4h} symmetry which results from the rotation of the three-membered vanadium oxide arc and two $\{As_2O_5\}$ groups over an eight-membered ring in α - $\{V_{14}^{IV}As_8O_{42}\}^{4-}$ by 90° around the S_4 axes (Fig. 15a and b). In the structure

Fig. 15 Polyhedral representation of the discrete "fully-reduced" $\alpha\text{-}[V_{14}^{IV}\text{As}_8\text{O}_{42}]^{4-}$ (a) and $\beta\text{-}[V_{14}^{IV}\text{As}_8\text{O}_{42}]^{4-}$ (b) polyoxoanions. Colour code: As, rose; O, red; $V^{IV}O_x$, sky-blue polyhedra.

Review Article Chem Soc Rev

crystal the $(C_4N_2H_{12})^{2+}$ piperazine cations, two HSO_4^- anions and terminal O atoms of the β-AsPOV building blocks are involved in strong hydrogen bonding interactions, thus generating a 3D network structure.

Other polyoxoanions with the same or a similar elemental composition were also reported. The antiferromagnetic compound [NH₂(CH₂CH₂)₂NH₂]₃[V₁₄As₈O₄₂(SO₄)]-6.5H₂O was obtained by the hydrothermal reaction in acidic solution at pH = 3 (Table 3). 133 Yang and colleagues showed that protonated $[NH_2(CH_2CH_2)_2NH_2]^{2+}$ amine molecules not only compensate the negative charge of the "fully-reduced" α-[SOV₁₄Ns₈O₄₂]⁶⁻ polyoxoanion but also assume space-filling and structuredirecting roles. The strong hydrogen bonds between the AsPOV building blocks, organic amine molecules, and crystal water molecules result in the formation of a 3D supramolecular array. The "fully-reduced" β -[SO₄@V^{IV}₁₄As₈O₄₂]⁶⁻ isomer was synthesised as the compound $(NH_4)_2(NMe_4)_4[V_{14}As_8O_{42}(SO_4)]$ under hydrothermal conditions. 134 The hydrothermal synthesis and characterisation of two other compounds $(H_2en)_{3.5}[V_{14}As_8O_{42}(PO_4)]\cdot 2H_2O^{135}$ and $(H_2enMe)_2[V_{14}As_8O_{42}(H_2O)]\cdot 3H_2O^{136}$ based on the "fullyreduced" α-polyoxoanions with encapsulated PO₄³⁻ and H₂O guests, respectively, were described as well (Table 3).

Discrete AsPOV with rubidium countercations. The above series of discrete, host-guest AsPOVs also includes the "fullyreduced" [Cl@V₁₄^{IV}As₈O₄₂]⁵⁻ polyoxoanion, which was shown to exhibit elongated square gyrobicupola topology that is also observed for $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ (Fig. 8a). This AsPOV pentaanion is the central component of the hydrothermally prepared compound Rb₅[V₁₄As₈O₄₂(Cl)]-2H₂O with a chain-like structure. 116 Interestingly, the [Cl@V₁₄^{IV}As₈O₄₂]⁵⁻ polyoxoanion could only be isolated in the presence of Rb⁺ cations (Table 3) and not with Na⁺, K⁺ or Cs⁺.

Transformation of $\{V_{14}As_8\}$ into $\{V_6As_8\}$ -type AsPOV. It is worth mentioning that, in the general case, the $[V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanion can be formally converted into the lower-nuclearity [V₆^{IV}As₈O₂₆]⁴⁻ polyoxoanion by removal of the central eightmembered ring composed of edge-sharing {VO₅} square pyramids. 137 The "fully-reduced" $\left[V_6^{IV}As_8O_{26}\right]^{4-}$ structure thus consists of four handle-like {As2O5} groups and six distorted {VO₅} square pyramidal units with the shortest V^{IV}...V^{IV} distance of ca. 4.5 Å. Furthermore, this AsPOV contains more As than V atoms, thus giving a high As/V ratio of 4/3, a very unusual situation in the structural chemistry of heteroPOVs discussed herein. The $[V_6^{IV}As_8O_{26}]^{4-}$ polyoxoanion crystallised under reducing conditions at room temperature as the compound (NnBu₄)₄-[V₆As₈O₂₆] (Table 3) and shows antiferromagnetic behaviour.

TMC-AsPOV hybrids without specific cation-anion interactions. The two antiferromagnetic compounds [Zn(2,2'-bipy)₃]₂[V₁₄As₈O₄₂- (H_2O)]- $4H_2O$ and $[Zn(2,2'-bipy)(dien)]_2[V_{14}As_8O_{42}(H_2O)]-2H_2O$ were prepared hydrothermally at pH = 7 using organic amines as reducing agents for the starting V₂O₅ material (Table 3). 138 These compounds are composed of the "fully-reduced" α -[H₂O@V₁₄^{IV}As₈O₄₂]⁴⁻ polyoxoanions with approximate D_{2d} symmetries and $[Zn(2,2'-bipy)_3]^{2+}$ and $[Zn(2,2'-bipy)(dien)]^{2+}$

countercations, respectively. In contrast to $[Zn(2,2'-bipy)_3]^{2+}$, the [Zn(2,2'-bipy)(dien)]²⁺ complexes are involved in extensive hydrogen bonding interactions with the oxygen atoms of the AsPOVs, thus yielding a densely packed 3D network in the crystal lattice of the $[Zn(2,2'-bipy)(dien)]_2[V_{14}As_8O_{42}(H_2O)]\cdot 2H_2O$ compound.

The nickel(π) and cobalt(π) analogues (2,2'-bipy)[Ni(2,2'-bipy)₃]₂- $[\alpha - V_{14}As_8O_{42}(H_2O)] \cdot 3H_2O$ and $[Co(2,2'-bipy)_3]_2[\alpha - V_{14}As_8O_{42}(H_2O)] \cdot (H_2O)$ $3H_2O$ of the $[Zn(2,2'-bipy)_3]_2[\alpha-V_{14}As_8O_{42}(H_2O)]\cdot 4H_2O$ compound were also hydrothermally synthesised (Table 3). 139 Similarly, the inorganic-organic hybrid compounds [Cu(en)₂]₂[V₁₄As₈O₄₂(H₂O)]-2.5H₂O, $[M(1,10-phen)_3]_2[V_{14}As_8O_{42}(H_2O)_{0.5}]\cdot 0.5H_2O$ (M = Mn, Cd) and [Co(dien)₂]₂[V₁₄As₈O₄₂(H₂O)]·3.5H₂O were obtained by pHcontrolled hydrothermal syntheses. 140 Notably, the α-[H₂O(a) $V_{14}^{IV}As_8O_{42}^{14}$ polyoxoanions in the crystal structure of $[Co(dien)_2]_2$ -[V₁₄As₈O₄₂(H₂O)]-3.5H₂O are linked by van der Waals forces into channels where the [Co(dien)₂]²⁺ complexes and H₂O molecules act as space-fillers.

The excitation and emission spectra of other hydrothermally prepared compounds [Zn(phen)₃]₂[V₁₄As₈O₄₂(H₂O)]·4H₂O and [Cd(phen)₃]₂[V₁₄As₈O₄₂(H₂O)]·2H₂O (Table 3) were reported that indicate fluorescence in the UV region with an emission peak at ca. 300 nm. 141 Although the authors claimed that these compounds feature a new type of the "fully-reduced" $[V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanion, namely the γ isomer with $d_{V\cdots V} =$ 3.01-3.04 Å, their structures are in fact characterised by co-crystallised polyoxoanions of α and β types with occupation factors of 0.5. For the rotational isomerism, electronic structures and acidity/basicity properties of "fully-reduced" [V₁₄E₈O₅₀]¹²⁻ heteroPOVs and their chalcogenide-substituted $[V_{14}^{IV}E_8O_{42}X_8]^{12-}$ derivatives (E = Si, Ge, Sn; X = S, Se, Te), see the theoretical work of Kondinski et al. 142 For comparison, Fig. 16 illustrates the α -, γ -, and β -isomeric vanadium oxide skeletons of the $\{V_{14}As_8\}$ -nuclearity AsPOVs.

TMC-AsPOV hybrids with specific cation-anion interactions. A large series of {V₁₄As₈O₄₂}-type polyoxoanions charge-balanced and covalently coordinated with various TMC complexes were presented by Yang, Xu, Wang, Peng, Das and coworkers. The inorganic-organic hybrid compounds with the α-[V₁₄^{IV}As₈O₄₂]⁴⁻ building blocks pillared by Zn(II) complexes [Zn(en)2][(H2O)- $Zn(en)_2V_{14}As_8O_{42}(H_2O)]\cdot H_2O$, $[\{(H_2O)Zn(1,10-phen)_2\}_2\{V_{14}As_8O_{42}-P_{14}As_8O_{42}\}]$ (H_2O) $]\cdot 4H_2O$, $[{(H_2O)Zn(2,2'-bipy)_2}{Zn(2,2'-bipy)_2}V_{14}As_8O_{42}-V_{14}As_8O_{42}]$ $(H_2O)_{0.5}$ ₂ $[\{(H_2O)Zn(2,2'-bipy)_2V_{14}As_8O_{42}(H_2O)_{0.5}\}_2\{Zn(2,2'-bipy)_2\}_2]$ $3H_2O$, and $[\{(H_2O)Zn(4,4'-bipy)\}_2\{V_{14}As_8O_{42}(H_2O)\}]\cdot 2H_2O$ were

Fig. 16 The "fully-reduced" vanadium oxide skeletons of α -/ γ -/ β - $[V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanions. The $\{As_2O\}$ moieties are not shown. Colour code: O, red; $V^{IV}O_x$, sky-blue polyhedra.

all synthesised under hydrothermal conditions. 143 These compounds display differing extended structures as well as different coordination modes of the organodiamine ligands (en, 1,10phen, 2,2'-bipy, and 4,4'-bipy) used in the synthesis reactions (Table 3). Notably, the formation of the crystalline products was shown to be strongly dependent on the acidic pH range (3-6), which is quite different from the pH (alkaline media) for reactions resulting in the TMC-supported GePOVs, and was seemingly not influenced by the reaction temperatures in the range 130-170 °C. The layered crystal structure of [Zn(en)₂][(H₂O)Zn(en)₂V₁₄As₈- $O_{42}(H_2O)$]· H_2O features the $[(H_2O)Zn(en)_2V_{14}As_8O_{42}(H_2O)]^{2-}$ anion, in which a single [Zn(en)2(H2O)]2+ moiety is attached to a terminal O atom from the eight-membered ring of the AsPOV, and the $[Zn(en)_2]^{2+}$ complex is the counteraction. The $[\{(H_2O)Zn(1,10-phen)_2\}_2\{V_{14}As_8O_{42}(H_2O)\}]\cdot 4H_2O$ compound shows the "fully-reduced" $[V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanion whose central eight-membered ring is doubly decorated with the [(H2O)Zn(1,10phen)₂]²⁺ complexes through covalent Zn-O bonds. The crystal structure is, furthermore, characterised by a 2D supramolecular array formed due to an extended hydrogen bond network. The crystal structure of $[{(H_2O)Zn(2,2'-bipy)_2}{Zn(2,2'-bipy)_2}V_{14}As_8O_{42} (H_2O)_{0.5}$ ₂ $[\{(H_2O)Zn(2,2'-bipy)_2V_{14}As_8O_{42}(H_2O)_{0.5}\}_2\{Zn(2,2'-bipy)_2\}_2]$. 3H₂O displays two crystallographically independent motifs, namely $[\{(H_2O)Zn(2,2'-bipy)_2V_{14}As_8O_{42}(H_2O)_{0.5}\}_2\{Zn(2,2'-bipy)_2\}_2]$ and $\label{eq:continuous} \mbox{$[\{(H_2O)Zn(2,2'\mbox{-}bipy)_2\}$} \mbox{$V_{14}As_8O_{42}(H_2O)_{0.5}]$. The structure $(H_2O)Zn(2,2'\mbox{-}bipy)_2$} \mbox{$(H_2O)Zn(2,2'\mbox{-}bipy)_2$} \mbox{$(H_2O)Zn(2,2'\mbox{-}bipy$ ture of the former, neutral dimer consists of two [(H2O)Zn(2,2'bipy)₂V₁₄As₈O₄₂(H₂O)_{0.5}]²⁻ hybrids, in which each AsPOV building block is coordinated with one $[(H_2O)Zn(2,2'-bipy)_2]^{2+}$ complex, and two [Zn(2,2'-bipy)₂]²⁺ complexes function as bridging groups between these two dianions. The structure of another neutral hybrid compound $[\{(H_2O)Zn(2,2'-bipy)_2\}\{Zn(2,2'-bipy)_2\}V_{14}As_8O_{42}-bipy\}_{14}As_8O_{42}-bipy\}_{14}As_8O_{42}-bipy\}_{14}As_8O_{42}-bipy]_{14}As_8O_{$ $(H_2O)_{0.5}$] consists of the $[(H_2O)Zn(2,2'-bipy)_2]^{2+}$ and $[Zn(2,2'-bipy)_2]^{2+}$ bipy)₂|²⁺ moieties covalently attached to the AsPOV building block via Zn-O bonds. In the structure, the $[(H_2O)Zn(2,2'-bipy)_2]^{2+}$ complex is involved in bonding to a terminal O atom from the eight-membered ring of $[V_{14}^{IV}\!As_{8}O_{42}]^{4-}$ and the $[Zn(2,2'\text{-bipy})_{2}]^{2+}$ complex to that of a {VO₅}-composed trimer capping the AsPOV ring. The crystal structure of [{(H₂O)Zn(4,4'-bipy)}₂{V₁₄As₈O₄₂-(H₂O)}]-2H₂O displays a 2D network where the adjacent AsPOVs are linked by two [(H₂O)Zn(4,4'-bipy)]²⁺ fragments through covalent Zn-O bonds. Thus, each polyoxoanion is surrounded by four bridging Zn(II) complexes coordinated to the terminal O atoms of the eight-membered vanadium oxide ring. The 2D network of this compound is further expanded into a 3D supramolecular structure via hydrogen bonds between water molecules and terminal oxygen positions of $[V_{14}^{IV}As_8O_{42}]^{4-}$. According to cyclic voltammograms, the above-described compounds exhibit quasi-reversible redox behaviour.

The extended solid-state structures of the hydrothermally prepared compounds [Zn(2,2'-bipy)₂]₂[V₁₄As₈O₄₂(H₂O)]·H₂O (Fig. 17a), $[Cd(2,2'-bipy)_3][Cd(dien)V_{14}As_8O_{42}(H_2O)], and [Ni(en)_2]_3[V_{14}As_8O_{42}-V_{14}As_8O_{42}]$ (HPO₃)]·4H₂O (Table 3) display the "fully-reduced" α -[V₁₄^{IV}As₈O₄₂]⁴⁻ polyoxoanions interconnected through the corresponding TMC complexes $[Zn(2,2'-bipy)_2]^{2+}$, $[Cd(dien)]^{2+}$, and $[Ni(en)_2]^{2+}$, respectively. 144 The Zn(II)- and Cd(II)-containing compounds organise into 1D chain structures and are characterised by

Fig. 17 Polyhedral representations of segments of the polymeric solidstate structures of $[Zn(2,2'-bipy)_2]_2[V_{14}As_8O_{42}(H_2O)]\cdot H_2O$ (a), $[Co(2,2'-bipy)_2]_2 [V_{14}As_8O_{42}(H_2O)]\cdot H_2O$ (b), and $[Cu(en)_2]_3[V_{14}As_8O_{42}(CO_3)]\cdot 10H_2O$ (c; only four [Cu(en)₂]²⁺ bridging groups are shown). Hydrogen atoms are omitted for clarity. Colour code: C, grey; N, blue; As, rose; O, red; V^{IV}, sky blue; V^{IV}O_x, sky-blue polyhedra; Co, plum; Cu, black; Zn, dark green.

overall antiferromagnetic coupling. In contrast, the Ni(II)containing compound exhibits a 2D structure and produces no signal for V^{IV} ions in the EPR spectrum at room temperature.

The antiferromagnetic compound [Ni(en)₂]₃[V₁₄As₈O₄₂(SO₄)]-4.5H₂O with a 2D layer structure was prepared under hydrothermal conditions (Table 3) and reveals strong covalent attachment between the adjacent α -[SO₄@V^{IV}₁₄As₈O₄₂]⁶⁻ polyoxoanions through V=O-Ni-O=V connectivities. 145 A 2D network is formed as POV is bound to four neighbouring polyoxoanions via an octahedrally coordinated Ni(II) centre.

The compounds $[\{Ni(en)_2\}_4(4,4'-bipy)_4\{Ni(H_2O)_2\}]_2[V_{14}As_8O_{42}-V_{14}As_8O_{42}]_2$ $(NO_3)_{4}\cdot 16H_2O$ and $[Ni(en)_2(H_2O)_2]_2[\{Ni(en)_2(H_2O)\}_2V_{14}As_8O_{42} (NO_3)$ $[Ni(en)_2] V_{14} As_8 O_{42} (NO_3)] \cdot 6H_2 O$ (Table 3) were hydrothermally prepared and showed high-dimensional organic-inorganic hybrid nanostructures. 146 The compound bearing 4,4'-bipy ligands consists of two bridging $[\{Ni(en)_2\}_4(4,4'-bipy)_4\{Ni(H_2O)_2\}]^{10+}$ fragments and four α-[NO₃@V₁₄^{IV}As₈O₄₂]⁵⁻ polyoxoanions which are joined through Ni-O bonds to form a pillared box-like structure with a cavity of ca. 600 Å³ (Fig. 18). In contrast to the previous compound, the compound $[Ni(en)_2(H_2O)_2]_2[\{Ni(en)_2(H_2O)\}_2$ $V_{14}As_8O_{42}(NO_3)[[Ni(en)_2]V_{14}As_8O_{42}(NO_3)]\cdot 6H_2O$ is based on the

Fig. 18 Two different views of the box-like motif found in the solid-state $structure \quad of \quad [\{Ni(en)_2\}_4(4,4'-bipy)_4\{Ni(H_2O)_2\}]_2[V_{14}As_8O_{42}(NO_3)]_4\cdot 16H_2O.$ Hydrogen atoms and lattice water molecules are omitted for clarity. Review Article Chem Soc Rev

"fully-reduced" β -[NO₃@V₁₄NS₈O₄₂]⁵⁻ polyoxoanions. Its crystal structure shows three crystallographically independent motifs: (i) bis-{Ni(en)₂(H₂O)}-decorated AsPOV anion [{Ni(en)₂(H₂O)}₂-V₁₄As₈O₄₂(NO₃)]⁻; (ii) 1D chain polymer consisting of $[{Ni(en)_2}_2V_{14}As_8O_{42}(NO_3)]^-$ monoanions; (iii) $[Ni(en)_2(H_2O)_2]^{2+}$ complexes.

The hydrothermal synthesis of 'metal-controlled' inorganicorganic self-assemblies with compositions [Ni(enMe)₃]₄- $[Ni(enMe)_2][V_{14}As_8O_{42}(NO_3)]_2 \cdot 8H_2O$ and $[Co(en)_3][Co(en)_2V_{14}$ As₈O₄₂(H₂O)]·16H₂O (Table 3) was reported. These antiferromagnetic compounds are based on the "fully-reduced" α-[V₁₄^{IV}As₈O₄₂]⁴⁻ polyoxoanions accommodating NO₃⁻ and H₂O as guests. 125 The crystal structure of the former AsPOV consists of $[Ni(enMe)_2 \{V_{14}As_8O_{42}(NO_3)\}_2]^{8-}$ dimers, four $[Ni(enMe)_3]^{2+}$ countercations and lattice H₂O molecules. The [Ni(enMe)₂- $\{V_{14}As_8O_{42}(NO_3)\}_2]^{8-} \ dimer \ is \ constructed \ from \ two \ ``fully$ reduced" [NO₃@V₁₄^{IV}As₈O₄₂]⁵⁻ moieties linked through the bridging [Ni(enMe)₂]²⁺ complex. The crystal structure of the latter compound is characterised by 1D chains consisting of the $[Co(en)_2V_{14}As_8O_{42}(H_2O)]^{2-}$ hybrids, $[Co(en)_3]^{2+}$ countercations and lattice H_2O molecules. The $[Co(en)_2]^{2+}$ complexes act here as bridging ligands for the neighbouring AsPOVs.

Another Co(II)-containing compound with the formula $[Co(2,2'-bipy)_2]_2[V_{14}As_8O_{42}(H_2O)]\cdot H_2O$ (Fig. 17b) and a tubular structure was prepared hydrothermally in acidified solution (Table 3). 147 The crystal structure of this solid being stable up to ca. 370 °C shows closed helical chains of {[Co(2,2'-bipy)₂]- $[V_{14}^{IV}As_8O_{42}(H_2O)]$ hybrid building blocks where the [Co(2,2'bipy)₂| $^{2+}$ complexes covalently link the α -isomeric AsPOVs through Co-O bonds.

A number of high-dimensional hybrid materials based on the $\alpha - [V_{14}^{IV}As_8O_{42}]^{4-}$ building block, namely $[M(bbi)_2]_2[V_{14}As_8O_{42}(H_2O)]$ (M = Co, Ni, Zn) and $[Cu(bbi)]_4[V_{14}As_8O_{42}(H_2O)]$ were synthesised under hydrothermal conditions (pH of ca. 5.0) where oxalic acid can act as a reducing agent for the VV source (Table 3). 148 These compounds containing the soft N-donor 1,1'-(1,4-butanediyl)bis(imidazole) (= bbi, C10H14N4) extend a series of POVtemplated structures including, e.g., that of the [H₄V₁₈O₄₆(SiO)₈-(dab)₄(H₂O)]-4H₂O compound bearing the bidentate dab ligand.⁹⁷ The isostructural $[M(bbi)_2]_2[V_{14}As_8O_{42}(H_2O)]$ (M = Co, Ni, Zn) compounds with antiferromagnetic properties are characterised by a binodal (4,6)-connected 2D network structure, Schläfli symbol $(3^4 \cdot 4^2)(3^4 \cdot 4^4 \cdot 5^4 \cdot 6^3)_2$, where each of the neighbouring AsPOVs is covalently coordinated to four bridging $[M(bbi)_2]^{2^+}$ complexes through M-O bonds. The coordination modes of the bbi ligands allow them to connect these four M2+ ions in such a manner that each polyoxoanion is located within a closed {M(bbi)}4 ring. In the structure of the compound [Cu(bbi)]₄[V₁₄As₈O₄₂(H₂O)] a 3D network is observed made up of the AsPOVs interacting covalently with the bbi-bridged Cu⁺ cations from the adjacent wave-like chains of the $[Cu(bbi)]_n$ moieties. The latter surrounding each polyoxoanion up and down results in the formation of 1D ladderlike [Cu(bbi)]⁺ double chains.

The compound $[Cu(en)_2]_3[V_{14}As_8O_{42}(CO_3)]\cdot 10H_2O$ with a 2D network structure was prepared hydrothermally (Table 3) and contains α -[CO₃@V₁₄NS₈O₄₂]⁶⁻ with a carbonate ion in the

inner void of the polyoxoanion. 149 In the solid state, each AsPOV is surrounded by six [Cu(en)₂]²⁺ bridging groups with Cu-O_{term}-V linkages (Fig. 17c).

Lanthanoid-AsPOV hybrids. The first representatives of AsPOVs with covalently attached agua-lanthanoid(III) complexes were reported in 2009. 150 Arumuganathan and Das isolated three isostructural $[\{Ln(H_2O)_6\}_2V_{14}As_8O_{42}(SO_3)]\cdot 8H_2O$ compounds (Ln = La^{III}, Sm^{III}, and Ce^{III}) from aqueous reaction solutions at room temperature using (NH₄)₆[V₁₄As₈O₄₂(SO₃)] and Ln(NO₃)₃·6H₂O as starting materials (Table 3). The main structural motif of the allinorganic {V₁₄As₈}-type compounds represents the "fully-reduced" $\beta - [V_{14}^{IV} As_8 O_{42}]^{4-}$ polyoxoanion with approximate D_{2d} symmetry, which encapsulate a sulfite anion. As was demonstrated by thermal analysis and mass spectrometry experiments, the aqua-Ln(III)-capped AsPOVs release gaseous SO₂ at temperatures 520-580 °C, whereas the (NH₄)₆[V₁₄As₈O₄₂(SO₃)] precursor releases SO₂ already at 480–520 °C. The crystal structures of these compounds display 2D layered coordination polymers where each of six $[Ln(H_2O)_6]^{3+}$ complexes surrounding the $[SO_3@V_{14}^{IV}As_8O_{42}]^{6-}$ polyoxoanion through one covalent Ln-O_{term}-V bond coordinates to two other adjacent AsPOVs. Thus, the aqua-Ln(III) complexes can indeed link to AsPOVs, which resulted in the formation of extended structures where La^{III} ions are nine-fold coordinated and reside in a monocapped square-antiprismatic coordination environment. Magnetic susceptibility studies performed for the samples with the 4f⁰-La^{III}, 4f⁵-Sm^{III} and 4f¹-Ce^{III} ions indicated that [{Ln(H₂O)₆}₂V₁₄As₈O₄₂(SO₃)]·8H₂O are antiferromagnetically coupled materials, with no significant coupling between the lanthanide(III) ions and the POV.

3.2.5 $\{V_{15}As_6\}$ -type polyoxoanions

Discrete AsPOV with potassium countercations. The first synthesised AsPOV dates back to 1988, when Müller and Döring published the compound K₆[V₁₅As₆O₄₂(H₂O)]·8H₂O which was prepared by reduction of vanadate with hydrazinium sulfate in the presence of As₂O₃ in aqueous solution at 85 °C (Table 3).¹⁵¹ This compound is composed of the "fully-reduced" [H2O@VIVAS6O42]6polyoxoanion with crystallographic D₃ symmetry and six K⁺ countercations. The "hydrated" potassium ions provide the networking of the AsPOVs in the crystal structure (rhombohedral cell; for hexagonal cell, see $K_6[V_{15}As_6O_{42}(H_2O)]\cdot 6H_2O)$. The $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$ polyoxoanion with an encapsulated H2O molecule (Fig. 19a) is the first member of the series of compounds with general formula $[V_{18-z}As_{2z}O_{42}]$ (z = 3). The structural motif of $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$ is derived from the $\left[V_{18}O_{42}\right]^{12-}$ structure by replacing three $\left\{VO_{5}\right\}$ units by three handle-like {As₂O₅} groups (for comparison, see $[V_{15}^{IV}Si_6O_{42}(OH)_6]^{6-}$ in Fig. 6c). This polyoxoanion thus consists of fifteen distorted {VO₅} square pyramids that are interlinked through the basal O vertices and edges and of six {AsO₃} trigonal pyramids. Interestingly, Müller and Döring noticed that this prominent AsPOV "may be regarded as a model for species that are formed during poisoning of the V_2O_5 catalyst (which contains V^{IV} centers) by arsenic.¹⁵¹

TMC-AsPOV hybrids without specific cation-anion interactions. The compound $[Zn(H_2O)_4]_2[H_2V_{15}As_6O_{42}(H_2O)]\cdot 2H_2O$ was obtained under hydrothermal conditions (Table 3) and is composed of the

Fig. 19 (a) The "fully-reduced" $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$ polyoxoanion. (b) The "fully-reduced" [$\{Zn(en)(enMe)\}V_{15}^{IV}As_6O_{42}\}^{4-}$ hybrid polyoxoanion. Hydrogen atoms and encapsulated water molecule are not shown. (c) A segment of the polymeric structure of $[Zn_2(dien)_3(H_2O)_2]_{0.5}[\{Zn_2(dien)_3\}V_{15}As_6O_{42}-$ (H2O)]-2H2O. (d) A segment of the extended solid-state structure of $[Co(enMe)_2]_3[V_{15}As_6O_{42}(H_2O)]\cdot 2H_2O$. (e) A segment of the extended solidstate structure of $[Cu(en)_2]_{1.5}[H_3V_{15}As_6O_{42}(H_2O)]\cdot 3H_2O$. Colour code: C, grey; N, blue; As, rose; O, red; V^{IV} , sky blue; $V^{IV}O_x$, sky-blue polyhedra; Co, plum; Cu, black; Zn, dark green.

doubly protonated $\left[H_2O@H_2V_{15}^{IV}As_6O_{42}\right]^{4-}$ polyoxoanion and two $[Zn(H_2O)_4]^{2+}$ countercations. ¹⁵³ In the structure, these two constituents are held together by hydrogen O-H···Oterm bonds, which results in the formation of a 3D network structure. In studies of third-order nonlinear optical (NLO) properties of $[Zn(H_2O)_4]_2[H_2V_{15}As_6O_{42}(H_2O)]\cdot 2H_2O$ the compound exhibited strong nonlinear absorption.

TMC-AsPOV hybrids with specific cation-anion interactions. The structures of two hydrothermally synthesised compounds $[Zn(en)_2][Zn(en)_2(H_2O)_2][\{Zn(en)(enMe)\}V_{15}As_6O_{42}(H_2O)]\cdot 4H_2O$ and $[Zn_2(enMe)_2(en)_3][\{Zn(enMe)_2\}V_{15}As_6O_{42}(H_2O)]\cdot 4H_2O$ (Table 3) consist of the $[{\rm Zn(en)(enMe)}]V_{15}^{\rm IV}{\rm As_6O_{42}(H_2O)}]^{4-}$ (Fig. 19b) and [{Zn(enMe)₂V₁₅^{IV}As₆O₄₂(H₂O)}]⁴⁻hybrid polyoxoanions whose AsPOV shells are coordinatively functionalised with Zn2+ complexes through Zn-O_{term}-V bonds. 154 Charge neutrality of the compounds is achieved by cationic {[Zn(en)₂][Zn(en)₂(H₂O)₂]}⁴⁺ and $[Zn_2(enMe)_2(en)_3]^{4+}$ complexes. By contrast, a $[\{\{Zn(en)_2\}_2-\}]$ $V_{15}As_6O_{42}(H_2O)\}_2\{Zn(en)_2\}]^{2-} \ dimer \ in \ another \ hydrothermally$ prepared compound $(Hen)_2[\{\{Zn(en)_2\}_2V_{15}As_6O_{42}(H_2O)\}_2\{Zn(en)_2\}]$ 3H₂O (Table 3) is charge-balanced by two singly protonated Hen⁺ cations. 155 The crystal structure of the latter compound shows two $[H_2O@V_{15}^{IV}As_6O_{42}\{Zn(en)_2\}_2]^{2-}$ building blocks which are joined by a bridging [Zn(en)₂]²⁺ unit through Zn-O bonds.

The "fully-reduced" [H₂O@V₁₅^{IV}As₆O₄₂]⁶⁻ polyoxoanions in the crystal structures of the antiferromagnetic compounds

 $[Zn_2(dien)_3(H_2O)_2]_0$ $[\{Zn_2(dien)_3\}V_1 = As_6O_4(H_2O)] \cdot 2H_2O$ (Fig. 19c. Table 3) and $[Ni(2,2'-bipy)_3]_2[\{Ni(en)_2\}V_{15}As_6O_{42}(H_2O)]\cdot 9.5H_2O$ are interlinked by [Zn₂(dien)₃]²⁺ and [Ni(en)₂]²⁺ moieties to form 1D helical chains and 1D infinite straight chains, respectively. 156 The 1D helical chains are involved in extensive hydrogen bonding interactions with discrete [Zn₂(dien)₃(H₂O)₂]⁴⁺ complexes, thus generating a 2D network structure; a further expansion of the hydrogen bond pattern involving [Zn₂(dien)₃]⁴⁺ bridging units results in a 3D supramolecular array. The 1D chains based on the $[H_2O@V_{15}^{IV}As_6O_{42}\{Ni(en)_2\}]^{4-}$ polyoxoanions have been reported as possessing molecular recognition ability for the chiral $[Ni(2,2'-bipy)_3]^{2+}$ guests.

The hydrothermally prepared compound [Co(enMe)₂]₃-[V₁₅As₆O₄₂(H₂O)]·2H₂O (Fig. 19d and Table 3) is characterised by a 2D structure where each [H₂O@V^{IV}₁₅As₆O₄₂]⁶⁻ polyoxoanion is coordinated by six [Co(enMe)₂]²⁺ moieties which in turn link the neighbouring AsPOVs to each other through Co-O_{term}-V bonds. 156 The crystal structure of the hydrothermally synthesised compound $[Co(en)_3][\{Co(en)_2\}_2V_{15}As_6O_{42}]\cdot 4H_2O$ (Table 3) shows an 1D infinite chain structure generated by Co-Oapical-V linkages. 157 The neighbouring [V₁₅^{IV}As₆O₄₂]⁶⁻ polyoxoanions are covalently linked through two six-coordinate cobalt(II) ions of μ_2 -{Co^{II}(en)₂}²⁺ moieties; isolated [Co^{II}(en)₃]²⁺ cations reside in interchain regions. This "fully-reduced" AsPOV exhibits weak antiferromagnetic exchange interactions between the vanadyl moieties.

A {V₁₅As₆}-type polyoxoanion with a higher degree of protonation was found in the hydrothermally synthesised compound $[Cu(en)_2]_{1.5}[H_3V_{15}As_6O_{42}(H_2O)]\cdot 3H_2O$ (Table 3). In the crystal structure, the "fully-reduced" $[H_2O@H_3V_{15}^{IV}As_6O_{42}]^{3-}$ polyoxoanions are bridged by [Cu(en)₂]²⁺ moieties leading to formation of a 1D sinusoidal chain (Fig. 19e). The series of protonated $[H_3V_{15}^{IV}As_6O_{42}]^{3-}$ and $[H_2V_{15}^{IV}As_6O_{42}]^{4-153}$ polyoxoanions was further expanded by a [HV₁₅IVAs₆O₄₂]⁵⁻ polyoxoanion as observed in the compound [Cu(enMe)₂]_{2.5}[HV₁₅As₆O₄₂(H₂O)]·2H₂O exhibiting antiferromagnetic properties. 136 This compound was prepared hydrothermally (Table 3) and shows a brick-wall-like 2D layer structure where the "fully-reduced" [H2O@HV15As6O42]5- polyoxoanions are doubly-bridged by the [Cu(enMe)₂]²⁺ moieties.

3.2.6 $\{V_{16}As_4\}$ -type polyoxoanion. The $\{V_{16}As_4O_{42}\}$ building block of D_{2h} symmetry, which is derived from the general formula $[V_{18-z}As_{2z}O_{42}]$ with z = 2, was isolated hydrothermally as the antiferromagnetic compound [Zn₂(dien)₃][{Zn(dien)}₂V₁₆As₄O₄₂(H₂O)]-3H₂O (Table 3).¹⁵⁹ Its crystal structure is characterised by 1D chains where the neighbouring, "fully-reduced" [H2O@V₁₆^{IV}As₄O₄₂]⁸⁻ polyoxoanions are bridged by dual mononuclear {Zn(dien)}²⁺ complexes through Zn-O bonds (Fig. 20). The dinuclear [Zn₂(dien)₃]⁴⁺ countercations reside in the interchain regions. To point out some structural relationships, this AsPOV can formally be converted, on the one hand, into the {V₁₈O₄₂} archetype by replacing two diagonal handlelike {As₂O₅} groups in the former by two square-pyramidal {VO₅} units or, on the other hand, the formal substitution of two diagonal {VO₅} square pyramids - that interlock two eight-membered rings in the {V₁₆As₄O₄₂} building block - by two additional {As₂O₅} groups will result in the polyoxoanion with the composition $\beta - [V_{14}^{IV} As_8 O_{42}]^{4-}$ (z = 4).

3.2.7 POVs with organoarsonate ligands

 $\{O_3AsPh\}/\{O_4AsPh\}-functionalised\ AsPOVs$. The vanadium oxide compounds containing phenylarsonate $(O_3AsPh)^{2-}$ moieties were first described in the early 1990s. The antiferromagnetic compound $[V_2O_4(HO_3AsPh)]\cdot H_2O$ with a layered mixed-valent (V^V/V^{IV}) structure was hydrothermally synthesised and characterised by Huan *et al.*, 160 while the compound displaying a phenylarsonate POV structure of higher nuclearity was described by Zubieta and colleagues 161,162 The mixed-valent $[H_2\{V_2^{IV}V_4^VO_{10}(O_3AsPh)_6\}]^{2-}$ polyoxoanion was isolated as the compound $(N_nBu_4)_2[H_2\{V_6O_{10}(O_3AsPh)_6\}]\cdot 2H_2O$ (Table 3). 161

Later on, the solvothermally prepared compounds (H₇O₃)₂- $(N_nBu_4)_2[(MeOH)_2V_{12}O_{14}(OH)_4(O_3AsPh)_{10}]\cdot H_2O$ and $(NEt_4)_2[V_{12}O_{12} (OH)_2(H_2O)_4(O_3AsPh)_{10}(HO_3AsPh)_4$ 6H₂O (Table 3) exhibiting, respectively, the nanoscopic organoarsonate POV cages with compositions $[(MeOH)_2@V_{12}O_{14}(OH)_4(O_3AsPh)_{10}]^{4-}$ (with approx. D_{2h} symmetry) and $[(H_2O)_2@V_{12}O_{12}(OH)_2(H_2O)_2(O_3AsPh)_{10}]$ $(HO_3AsPh)_4$ ²⁻ that cannot be derived from the $\{V_{18}O_{42}\}$ archetype. 162 The "fully-reduced" [(MeOH)₂@ $V_{12}^{IV}O_{14}(OH)_4(O_3AsPh)_{10}]^{4-}$ polyoxoanion is built up of edge- and corner-sharing {VO₅} square pyramids, phenylarsonate tetrahedra and square pyramids and can be regarded as being composed of two {V₄^{IV}O₅(O₃AsPh)} fragments bridged by two $\{V_2^{IV}O_2(OH)_2(O_3AsPh)_4\}^{6-}$ moieties. The dianionic, "fully-reduced" AsPOV [(H2O)2@V12O12(OH)2- $(H_2O)_2(O_3AsPh)_{10}(HO_3AsPh)_4]^{2-}$ consists of $\{VO_5\}$ square pyramids, {VO₆} octahedra and phenylarsonate tetrahedra and square pyramids. The structure of this AsPOV is characterised by two $\{V_5^{IV}O_6(O_3AsPh)_3\}^{2+}$ fragments bridged by two $\{V^{IV}(OH)-$ (H₂O)(O₃AsPh)₂(HO₃AsPh)₂\³⁻ moieties. The geometric equivalence of the {AsPh}⁴⁺ groups to {VO}³⁺ by virtue of the nearly identical AsV-O and VV-O bond lengths was stressed by Khan and Zubieta.

In 2011, Zhang and Schmitt reported a unique series of symmetrical nanoscopic vanadium oxide supramolecular coordination cages functionalised with phenylarsonate ligands (Fig. 21) and exploited the topologies of their hollow structures together with the template effects of the octahedral $\{X_2(H_2O)_{6-z}\}$ guest assemblies (X = Br, Cl and z = 2, 4, 6). 163 Such "fully-reduced" V^{IV} , mixed-valent V^{V}/V^{IV} and fully-oxidised V^{V} AsPOVs characterised by the high-nuclearity $\{V_{16}As_8\}$, $\{V_{16}As_{10}\}$, $\{V_{20}As_8\}$ and $\{V_{24}As_8\}$ cages were found in the blue compounds $\{HNEt_3\}_2[\{Br_2(H_2O)_4\}(V^{IV}O)_{16}-(OH)_8(O_4AsPh)_2(O_3AsPh)_8]$ -6MeCN and $\{HNEt_3\}_2[\{Cl_2(H_2O)_4\}-(V^{IV}O)_{16}(OH)_8(O_4AsPh)_2(O_3AsPh)_8]$ -2H₂O as well as the green compounds $\{H_5\}_3[\{Cl_4(H_2O)_2\}(V^{V}O)_{16}O_{16}(O_3AsPh)_8]$ Cl·4H₂O·3MeCN,

Fig. 21 Polyhedral representations of the "fully-reduced" $\{V_{16}As_{10}\}$ -nuclearity AsPOVs (top) as well as the fully-oxidised $\{V_{16}As_8\}$ -nuclearity AsPOV, and the mixed-valent $\{V_{20}As_8\}$ - and $\{V_{24}As_8\}$ -nuclearity AsPOVs (bottom). Encapsulated octahedral guest assemblies are omitted for clarity. Colour code: C, grey; As, rose; O, red; $V^{IV}O_{x}$, sky-blue polyhedra; $V^{V}O_{x}$, light-orange polyhedra; $V^{V}V^{IV}O_{x}$, dark-grey polyhedra.

 $[\{Cl_4(H_2O)_2\}(V^{VO})_{16}(V^{IV}O)_4O_{16}(OH)_4(O_3AsPh)_8]\cdot 7H_2O\cdot 3MeCN$ and $H_{10}[\{Cl_6\}(V^VO)_{16}(V^{IV}O)_8O_{24}(O_3AsPh)_8]Cl_4\cdot 10H_2O\cdot 2MeCN$ (Table 3). Their structures contain four- $({O_3AsPh})$ or five-fold $({O_4AsPh})$ coordinated As centres. The isomeric, "fully-reduced" {V₁₆As₁₀} cages in the blue compounds consist of sixteen {VO₅} squarepyramids and ten fully deprotonated phenylarsonate ligands. Their AsPOV building block represents a modified $[V_{18}O_{42}]^{12}$ structure in which two {VO₅} caps on one diagonal are replaced with two {O₄AsPh} moieties and two groups by four {O₃AsPh} moieties slice the structure horizontally to isolate an eightmembered {VO₅}-belt (Fig. 21, top). The key structural difference between the {V₁₆As₁₀} cages accommodating octahedral {Br₂(H₂O)₄} and {Cl₂(H₂O)₄} guest templates in their inner voids is that the two convex {V4VO5(O3AsPh)} moieties in the Cl-containing AsPOV are rotated by 45° (isomer 2). This structural change is the result of the considerably different ionic radii of Br and Cl ions and the energies of V···Br and V···Cl interactions. The encapsulated symmetrical {Br₂(H₂O)₄} and {Cl₂(H₂O)₄} octahedra with the Br and Cl⁻ ions situated in the apical positions show Br···H₂O and Cl···H₂O distances ranging from 3.13 to 3.36 Å and from 3.03 to 3.18 Å, respectively. In addition, Br. . Br distance of 5.28 Å is slightly shorter than the Cl···Cl distance of 5.31 Å. The intramolecular V···Br and V···Cl separations are between 3.47 and 3.51 Å. It was concluded that the nature and geometry of these octahedral guest assemblies determines the nuclearity, size, and topology of the produced organoarsonate POV cages.

The fully-oxidised $\{V_{16}As_8\}$ - and mixed-valent $\{V_{20}As_8\}$ - and $\{V_{24}As_8\}$ -type building blocks (Fig. 21, bottom) of the above-mentioned green compounds were synthesised using $Dy(NO_3)_3$ · nH_2O ($n\approx 6$), where presumably nitrate acts as an oxidant, different quantities of which was shown to influence the nuclearity of these AsPOV cages and the formal oxidation states

of their V atoms. Thus, a gradual increase in the amount of the oxidant led ultimately to the fully-oxidised {V₁₆As₈}-nuclearity cage. The molecular structures of these three AsPOVs are constructed of sixteen, twenty and twenty-four edge- and cornersharing {VO₅} square-pyramids, respectively. Each POV shell is ligated by eight phenylarsonate groups. The {V₁₆As₈}-toroid cage encapsulates an octahedral {Cl₄(H₂O)₂} guest template, in which the closest Cl···Cl/Cl···H₂O distances amount to 3.97 Å/3.41 Å. The intramolecular V···Cl separations range from 2.82 Å to 3.02 Å. The $\{V_{20}As_8\}$ cage can be seen as the toroidal structure of $\{V_{16}As_8\}$ decorated with two $\{(V^{IV}O)_2(\mu_2\text{-OH})_2\}$ units and is stabilised by the $\{Cl_4(H_2O)_2\}$ assembly as well. The $Cl \cdot \cdot \cdot Cl$ and $Cl \cdot \cdot \cdot H_2O$ distances in this $\{Cl_4(H_2O)_2\}$ octahedron are 3.98 Å and 3.24-3.80 Å, respectively. The closest intramolecular V···Cl distances lie in the range 2.81–3.10 Å. The two encapsulated H_2O molecules and the V ions of the $\{(V^{IV}O)_2(\mu_2\text{-OH})_2\}$ entities are involved in V···Owater interactions at a distances of 2.36 Å. The $\{V_{24}As_8\}$ cage encapsulates a $\{Cl_6\}$ aggregate with $d_{Cl\cdots Cl}$ = 3.91-4.01 Å the vertices of which are capped by six square {V₄O₈} fragments with electrophilic inner and nucleophilic outer environments. The closest V···Cl separations are in the range 2.94–3.033. The Archimedean body $\{V_{24}\}$ polyhedron (14 faces, 36 edges, 24 vertices) deduced from the mixed-valent $\{(V^VO)_{16}(V^{IV}O)_8O_{24}(O_3AsPh)_8\}$ fragment that can be regarded as a Keplerate displays a truncated octahedral topology. The {V₂₄} polyhedron in the {V₂₄As₈} cage can thus be classified as one of the thirteen Archimedean solids. 164 The vanadium skeletons of some of the discussed organoarsonate POV cages are illustrated in Fig. 22.

 $\{O_3AsC_6H_4-4-NH_2\}$ -functionalised AsPOVs. The group of Schmitt also reported two nanoscopic cages with compositions [V₁₄O₁₆- $(OH)_8(O_3AsC_6H_4-4-NH_2)_{10}]^{4-}$ (Fig. 23), which shows a defect AsPOV structure from the {V₁₆As₁₀}-nuclearity cage (isomer 1, Fig. 21), and $[V_{10}O_{18}(O_3AsC_6H_4-4-NH_2)_7(DMF)_2]^{5-}$. The compounds based on these AsPOVs were isolated from the condensation reactions under reducing conditions in aqueous solution (Table 3). The different nature of acids (HCl and HNO₃) used in the synthesis of these compounds strongly influenced the nuclearity of the cages, resulting in the $\{V_{14}As_{10}\}$ - and $\{V_{10}As_7\}$ -type polyoxoanions, respectively. In contrast to the {O₃AsPh}/{O₄AsPh}functionalised AsPOVs, the POV shells of these polyoxoanions are decorated with terminal (4-aminophenyl)arsonate ligands {O₃AsC₆H₄-4-NH₂}. Their skeleton structures are composed exclusively of {VO₅} square-pyramids. Whereas the electrophilic void of the "fully-reduced" $\{V_{14}As_{10}\}$ cage (dimensions: $5.8 \times 5.9 \times 5.9 \text{ Å}$)

Fig. 22 Topological representations of the vanadium skeletons deduced from some high-nuclearity organoarsonate POV cages represented in Fig. 21 and 23. Colour code: V^{IV}, sky blue; V^V, light orange.

Fig. 23 The "fully-reduced" $[V_{14}^{IV}O_{16}(OH)_8(O_3AsC_6H_4-4-NH_2)_{10}]^{4-}$ (left) and $[V_{12}^{IV}O_{14}(OH)_4(O_3AsC_6H_4-4-NH_2)_{10}]^{4-}$ (right) AsPOVs. H omitted for clarity. Colour code: C, grey; N, blue; As, rose; O, red; VIVOx, sky-blue polyhedra.

with an almost ideal cubic arrangement of the As atoms contains two Cl ions and four H2O molecules forming a stabilising octahedral assembly, the mixed-valent asymmetric {V₁₀As₇} cage is characterised by a hexagonal packing due to the amine functionalities engaged in hydrogen bonds in the structure.

The $[V_{12}O_{14}(OH)_4(O_3AsC_6H_4-4-NH_2)_{10}]^{4-}$ polyoxoanion with the V^{IV}/arsonate nuclearity [12(VO₅):10(O₃AsR)], lower than that [14(VO₅): 10(O₃AsR)] of the above-mentioned [V₁₄O₁₆(OH)₈- $(O_3AsC_6H_4-4-NH_2)_{10}]^{4-}$ polyoxoanion, was isolated as the compound $Na_4(H_2O)_{10}[\{V_{12}O_{14}(OH)_4(H_2O)_3(O_3AsC_6H_4-4-NH_2)_{10}\}]$ 1.5DMF-1.25H₂O (Table 3) from a condensation reaction involving p-arsanilic acid in a H₂O/dimethylformamide (DMF) mixture. 166 The main structural difference between these two AsPOVs (Fig. 22) is the number of the {VO₅} square pyramids sandwiched between two tetranuclear $\{LV_4^{IV}O_{12}\}$ subunits where L is the (4-aminophenyl)arsonate ligand. The {V14As10} cage comprises two separated hydroxy-bridged {O₄V^{IV}(OH)₂V^{IV}(OH)₂- $V^{IV}O_4$ trimers, whilst the $\{V_{12}As_{10}\}$ cage has only two separated, partially hydrated {O₄V^{IV}(OH)₂V^{IV}O₄} dimers. The {VO₅} square pyramids in the belt of each of these molecular cages are connected to two tetranuclear $\{LV_4^{IV}O_{12}\}$ subunits via additional eight (4-aminophenyl)arsonate ligands (Fig. 23). The synthesis and structural characterisation of the compound Na₅[V₅O₉(O₃AsC₆H₄-4-NH₂)₄] 20.5H₂O·3DMF with the low-nuclearity inorganic-organic calix-type building block [V₅O₉(O₃AsC₆H₄-4-NH₂)₄]⁵⁻ comprising mixed-valent VV/VIV atoms were described as well (Table 3).166 The preliminary magnetic studies performed for these two compounds showed the presence of antiferromagnetic exchange interactions and S = 0 ground states.

An example of the {O₃AsC₆H₄-4-NH₂}-functionalised AsPOV with a quasi-planar, polycyclic-type structure was also reported. The fully-oxidised $[V_{10}^{V}O_{24}(O_{3}AsC_{6}H_{4}-4-NH_{2})_{3}]^{4-}$ (Fig. 24a) polyoxoanion was isolated as the compound (N_nBu₄)₂(NH₄)₂[V₁₀O₂₄- $(O_3AsC_6H_4-4-NH_2)_3$ (Table 3). The structure of this AsPOV can be regarded as a $[V_9O_{21}(O_3AsC_6H_4-4-NH_2)_3]^{3-}$ toroid that encloses a {VO₃} unit in the centre of the wheel. The most unique feature of $[V_{10}^{V}O_{24}(O_3AsC_6H_4-4-NH_2)_3]^{4-}$ is that it contains a wheel-type $[V_7O_{24}]^{13-}$ substructure (Fig. 24b). Remarkably, the structure of this heptanuclear [V₇O₂₄]¹³⁻ polyoxoanion displays striking similarities to the Anderson-type structures, e.g. of $[\text{TeM}_6\text{O}_{24}]^{6-}$, 167 $[\text{M}_7\text{O}_{24}]^{6-}$ (M = Mo, W), 168 and $[\text{Bi}_7\text{I}_{24}]^{3-169}$ (Fig. 24c). The overall composition of $[V_{10}^{V}O_{24}(O_3AsC_6H_4-4-NH_2)_3]^{4-}$

Review Article Chem Soc Rev

Fig. 24 The fully-oxidised $[V_{10}^VO_{24}(O_3AsC_6H_4-4-NH_2)_3]^{4-}$ polyoxoanion (a), its $[V_7O_{24}]^{13-}$ core (b), and the structurally related $[Bi_7I_{24}]^{3-}$ polyiodoanion (c). Colour code: C, grey; N, blue; As, rose; O, red; VV, light orange; Bi, brown: I, violet.

formally consists of a double layer of polyhedra (bicapped Anderson type), with the one being composed of $[V_7O_{24}]^{13-}$ and the second, of a [V₃(RAsO₃)₃]⁹⁺ ring. Another interesting feature is that it can be reversibly reduced by one electron to give the greenbrown compound with composition $[V_{10}O_{24}(O_3AsC_6H_4-4-NH_2)_3]^{5-}$. According to electrochemical and magnetic measurements, this compound as well as the aforementioned (N_nBu₄)₂[H₂{V₆O₁₀-(O₃AsPh)₆}]·2H₂O¹⁶¹ are characterised by extensive electron storage and coupled electron-proton transfer processes.

3.2.8 Corollary for AsPOVs. The AsPOVs discussed so far exhibit various symmetries as exemplified by $[V_8^{IV}V_4^VAs_8O_{40}]^{5-1}$ and $\beta - [V_{14}^{IV} A s_8 O_{42}]^{4-}$ with D_{4h} , $\alpha - [V_{14}^{IV} A s_8 O_{42}]^{4-}$ with D_{2d} , $[H_3 K V_4^{IV} - V_4]^{4-}$ $V_8^{V}As_3O_{39}(AsO_4)]^{6-}$ with C_3 , $[V_{14}^{IV}As_8O_{42}]^{4-}$ with S_4 , $[V_{15}^{IV}As_6O_{42}]^{6-}$ with D_3 , and $[V_{16}^{IV}As_4O_{42}]^{8-}$ with D_{2h} . Fully-oxidised, mixed-valent and "fully-reduced" AsPOVs with As atoms in their formal oxidation states of +3 and, more rarely, +5, were reported to date. AsPOVs a variety of structural motifs, ranging from sphericalshaped to wheel-type structures. Dimensionalities from 0D (isolated AsPOVs) to 3D were observed in the solid state. The AsPOVs easily undergo transition metal functionalisation, resulting in novel inorganic-organic frameworks where multidentate organoamines are very commonly captured by transition metal ions introduced into the backbones of the AsPOVs. The hydrogen bonds characteristically expand the dimensionality of the AsPOV structures into 3D networks.

The discovery of the seminal [H2O@VIVAS6O42]6- polyoxoanion151 that was shown to act as a textbook example for quantum spin frustration and as a qubit with relatively long coherence lifetimes paved the way for studies focussed on the optical, electronic and magnetic properties of other iso- and heteroPOVs. The nanoscale magnetism of this {V₁₅}-type AsPOV with a symmetrical layer structure of spin centres and spin frustration effects in the central VIV triangle is now welldocumented. The $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$ polyoxoanion is a lowspin (spin-1/2) molecular nanomagnet and its characteristics were explored extensively: non-adiabatic Landau-Zener transitions, 170 low-energy spin excitations by elastic neutron scattering study of K₆[V₁₅As₆O₄₂]·9D₂O, ¹⁷¹ low-energy excitations from proton NMR and μSR,¹⁷² adiabatic Landau-Zener-Stückelberg transitions with or without dissipation, 173 mechanism of groundstate selection, 174 local spin moment configuration determined by NMR, 175 static magnetisation at ultra-low temperatures, 176 quantum oscillations, 177 and direct spin-phonon transitions. 178 In general, such AsPOVs show extraordinary magnetic properties and can be used as models to study different fundamental phenomena as e.g. spin frustration 179 and frustrated spin coupling, spin-phonon bottlenecks and butterfly hysteresis, 180 Dzyaloshinsky-Moria interactions and other splitting effects, ¹⁸¹ molecular-scale switching, 182 quantum-spin tunnelling, spin coherence and low-temperature spin relaxation processes. 183

3.3 Polyoxovanadatoantimonates (SbPOVs)

3.3.1 Discrete SbPOVs

 $\sqrt{V_{14}Sb_8}$ -type polyoxoanions. The "fully-reduced" α - H_2O $V_{14}^{IV}Sb_8O_{42}]^{4-}$ polyoxoanion, with rhombicuboctahedral topology and isostructural to $\alpha - [V_{14}^{IV} As_8 O_{42}]^{4-}$ (Fig. 15a), was isolated as the compound $[(H_2en)_2\{V_{14}Sb_8O_{42}(H_2O)\}]\cdot(en)\cdot 4H_2O$ under hydrothermal conditions 184 (Table 4). Its crystal structure shows a 1D double-chain in which the sphere-like α-isomeric SbPOVs are interlinked through non-bonding Sb...O contacts of 2.74 and 2.79 Å. The intermolecular N-H···O hydrogen bonds between the terminal oxygen atoms of the SbPOVs and the hydrogen atoms of ethylenediamine molecules were observed.

The β-isomeric $[V_{14}^{IV}Sb_8O_{42}]^{4-}$ polyoxoanion is a component of the solvothermally prepared ammonium salt (NH₄)₄[V₁₄Sb₈O₄₂]. 2H₂O (Table 4).¹⁸⁵ The structure is further characterised by comparably short intercluster Sb···O contacts of 2.83-2.98 Å.

 $\{V_{15}Sb_6\}$ -type polyoxoanion. The compound $(H_3 tren)_2[V_{15}-V_{15}]$ Sb_6O_{42}]·0.33(tren)· nH_2O (n = 3-5) was obtained under solvothermal conditions (Table 4),186 comprising an isostructural antimony analogue $[V_{15}^{IV}Sb_6O_{42}]^{6-}$ of the molecular magnet $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$. The nanosized structure of this "fullyreduced" polyoxoanion (Fig. 25a, left) is viewed as a derivative of the {V₁₈O₄₂} archetype where three {VO₅} square-pyramids are substituted by three handle-like {Sb₂O₅} groups. The structure features {V₁₅}-nuclearity building bocks being arranged in hexagonal layers via weak, intercluster Δ(Sb-μ-O···Sb-μ-O···Sb-μ-O) interactions within the distances of ca. 2.9 Å, thus resulting in the formation of trimeric super-structures ($[V_{15}^{IV}Sb_6O_{42}]^{6-}$)₃. The spin-1/2 ground structure of the [V₁₅^{IV}Sb₆O₄₂]⁶⁻ polyoxoanion "represents an interesting reference system for the concise characterisation of the microscopic magnetism of these spin 1/2 triangle systems, 186 (Fig. 25a, right).

 $\{V_{16}Sb_4\}$ -type polyoxoanion. The above class of SbPOV-based compounds with the general formula $[(Hamine)_m V_{18-z}Sb_{2z}O_{42}]$ nH_2O (z = 2-4) was extended by a new member of this series, namely (H₂aep)₄[V₁₆Sb₄O₄₂]·2H₂O, prepared under solvothermal conditions (Table 4).185 This compound is composed of the "fullyreduced" $[V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanion $(D_{2h}$ symmetry) chargebalanced by four doubly protonated $(C_6H_{17}N_3)^{2+}$ groups (=H₂aep). The structure of the SbPOV showing the common rhombicuboctahedral topology consists of sixteen {VO₅} square pyramids and four {SbO₃} trigonal pyramids and can be interpreted as being derived from the {V₁₈O₄₂} archetype when replacing two {VO₅} units in the latter with two {Sb2O5} groups. In the structure of (H₂aep)₄[V₁₆Sb₄O₄₂]·2H₂O, the SbPOVs are connected into infinite chains via intercluster Sb···O interactions of ca. 2.85 Å (Fig. 25b).

Fig. 25 (a) Left: Polyhedral representation of the "fully-reduced" $[V_{15}^{VV}Sb_6O_{42}]^{6-}$ polyoxoanion isolated as the compound $(H_3 tren)_2 [V_{15} Sb_6 O_{42}] \cdot 0.33 (tren) \cdot nH_2 O$ with n = 3-5. Right: Ball-and-stick representation of $[V_{15}^{IV}Sb_6O_{42}]^{6-}$ emphasising the equilateral $S = 1/2 V_3^{IV}$ triangle that defines the low-temperature magnetic properties. (b) A segment of the extended solid-state structure of $(H_2aep)_4[V_{16}Sb_4O_{42}]\cdot 2H_2O$, highlighting the weak $Sb\cdots O$ interactions that interlink the neighbouring SbPOVs. Colour code: Sb, dark yellow; O, red; V^{IV} , sky blue; $V^{IV}O_x$, sky-blue polyhedra.

3.3.2 Vanadyl(IV)-extended SbPOV. The solvothermal synthesis of the compound $[V_{16}Sb_4O_{42}(H_2O)\{VO(dach)_2\}_4]\cdot (dach)\cdot 10H_2O$ containing a neutral SbPOV building block¹⁸⁷ (Table 4) can be derived from a general composition {V18-2Sb22O42} showing a modified $[V_{18}O_{42}]^{12-}$ structure where two $[VO_5]^{6-}$ square pyramids are replaced by two diagonal-lying, handle-like [Sb₂O₅]⁴⁻ groups (Fig. 26). The terminal O atoms of two diagonally oriented, non-substituted {VO₅} square pyramids and those from the two {VO₅} square-pyramids interlocking two orthogonal eight-membered rings are involved in the bonding to the four square-pyramidal [V^{IV}O(dach)₂]²⁺ complexes. These {N₄VO}-type constituents cause charge neutrality. Their coordination results in the discrete [V₁₆Sb₄O₄₂{VO(dach)₂}₄] nanostructure with a diameter of ca. 17.5 Å. The compound is soluble in polar organic solvents (methanol, ethanol, and dimethylformamide) and may find application in homogeneous redox catalysis. According to the magnetic susceptibility data, the coupling between the O-bridged V^{IV} ions of the four $\{N_4VO\}$ groups and those of the $\{V_{16}Sb_4O_{42}\}$ building block is very weak. The "fully-reduced" $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanion $(D_{2h}$ symmetry) itself is characterised by strong antiferromagnetic coupling between the spin-1/2 vanadyl {VO}²⁺ moieties.

3.3.3 SbPOVs with covalent Sb-N bonds. First organo-SbPOV structures formed due to the covalent attachment of the primary and secondary amines to the SbPOVs were reported in 2011. The compounds $[V_{14}Sb_8(Haep)_4O_{42}(H_2O)]\cdot 4H_2O$ and $(H_2aep)_2[V_{15}Sb_6(Haep)_2O_{42}(H_2O)] \cdot 2.5H_2O$ were hydrothermally synthesised upon adjustment of pH to the alkaline media (Table 4). The crystal structures of these compounds show hexagonal layers and rows of SbPOVs with intercluster Sb···O

Fig. 26 The "fully-reduced" $[H_2O@V_{16}^{IV}Sb_4O_{42}\{VO(dach)_2\}_4]$ self-assembly (right) and its constituents, $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ (left) and $[V^{IV}O(dach)_2]^{2+}$ (middle). Hydrogen atoms are not shown. Colour code: C, grey; N, blue; Sb, dark yellow; O, red; VIVOx, sky-blue polyhedra.

distances of ca. 2.73 Å in the (001) and of >3 Å in the (100) planes. The Sb atoms of the β -[H₂O@V₁₄^{IV}Sb₈O₄₂]⁴⁻ and [H₂O@ V₁₅^{IV}Sb₆O₄₂]⁶⁻ polyoxoanions are covalently bound to ammonium groups $(C_6H_{16}N_3)^+$ (=Haep), thus resulting in Sb-N bonds lengths ranging from 2.50 to 2.54 Å. Interestingly, the molecular charge of the {V₁₄}-nuclearity polyoxoanion is completely neutralised by the four monoprotonated 1-(2-aminoethyl)piperazine groups, while the charge of the {V15}-nuclearity polyoxoanion in the respective compound is only partly compensated by two Haep groups covalently attached to the Sb atoms of the {Sb2O5} handle-like groups (Fig. 27). Hence, $[V_{14}Sb_8(Haep)_4O_{42}(H_2O)]$ 4H₂O is a neutral compound and (H₂aep)₂[V₁₅Sb₆(Haep)₂O₄₂-(H₂O)]-2.5H₂O is a zwitterionic complex composed of two doubly protonated $(C_6H_{17}N_3)^{2+}$ amine countercations (=H₂aep) and the "fully-reduced" $[H_2O@V_{15}^{IV}Sb_6(Haep)_2O_{42}]^{4-}$ polyoxoanion. The $(C_6H_{16}N_3)^+$ groups in the compound $[V_{14}Sb_8(Haep)_4O_{42}(H_2O)]$ 4H₂O coordinate to the Sb sites of the handle-like {Sb₂O₅} groups through terminal NH₂ groups of 1-(2-aminoethyl)piperazinium as well as the N atoms of the piperazinium rings. The amine ligands in $[H_2O@V_{15}^{IV}Sb_6(Haep)_2O_{42}]^{4-}$ favour only the second coordination type to the Sb^{III} atoms. The magnetic properties of two compounds are characterised by strong antiferromagnetic interactions between the spin-1/2 vanadyl ${VO}^{2+}$ moieties. In line with the low or neutral charge of the clusters, both compounds are soluble in methanol and ethanol. The UV/Vis spectra of their solutions are

Fig. 27 The "fully-reduced" organo-SbPOVs [H2O@V14Sb8(Haep)4O42] (a) and $[H_2O@V_{15}^{IV}Sb_6(Haep)_2O_{42}]^{4-}$ (b). Colour code: C, grey; N, blue; Sb, dark yellow; O, red; $V^{IV}O_x$, sky-blue polyhedra.

characterised by a strong absorption band at ca. 230 nm and a weaker shoulder at ca. 280 nm.

3.3.4 TMC-supported SbPOVs

Zinc-SbPOV hybrids. Two organic-inorganic hybrid solids $[Zn_2(dien)_3][\{Zn(dien)\}_2V_{16}Sb_4O_{42}(H_2O)]\cdot 4H_2O \text{ and } [Zn(dien)_2]_2$ [{Zn(dien)}₂(V₁₄Sb₈O₄₂)₂(H₂O)]·4H₂O were obtained by pH-controlled hydrothermal syntheses (Table 4). 189 These compounds contain the $[V_{16}^{IV}Sb_4O_{42}]^{8-}$ and $\beta\text{-}[V_{14}^{IV}Sb_8O_{42}]^{4-}$ building blocks and in the solid state are arranged as 1D infinite linear and zig-zag chains, respectively. In the structure of the former compound, neighbouring $[H_2O@V_{16}Sb_4O_{42}]^{8-}$ polyoxoanions with D_{2h} symmetry are linked by the [Zn(dien)]²⁺ bridging groups via covalent Zn-O bonds (Fig. 28a), while the [Zn₂(dien)₃]⁴⁺ complexes resemble structurally discrete countercations. Similarly to the previous compound, the crystal structure of [Zn(dien)₂]₂[{Zn(dien)₂- $(V_{14}Sb_8O_{42})_2(H_2O)]\cdot 4H_2O$ contains neighbouring $\beta - [V_{14}^{IV}Sb_8O_{42}]^{4-1}$ polyoxoanions that are bridged by single [Zn(dien)]²⁺ moieties through covalent Zn-O bonds (Fig. 28b). The two [Zn(dien)₂]²⁺ cations compensate the negative charge of the [{Zn(dien)}2- $(V_{14}Sb_8O_{42})_2(H_2O)]^{4-}$ assembly.

A $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanion in which the geometric position of the handle-like {Sb₂O₅} groups reduce the symmetry of the $\{V_{16}\}$ skeleton to C_2 (vs. D_{2h} symmetry reported for all hitherto characterised {V₁₆}-nuclearity AsPOVs and SbPOVs) was also identified (Fig. 29). For comparison, the $[V_{16}^{IV}Si_4O_{46}]^{12-}$ polyoxoanion illustrated in Fig. 6a has D_{2h} symmetry, whereas the $[V_{16}^{IV}Ge_4O_{42}(OH)_4]^{8-}$ in Fig. 8a also displays C_2 symmetry. Such changes in the SbPOV structure influenced the geometrical parameters, specifically the V···V distances of this polyoxoanion. While the shortest non-bonding V···V distances in the C_2 -symmetrical $[H_2O@V_{16}Sb_4O_{42}]^{8-}$ structure are between 2.73 and 3.10 Å, those in the isonuclear, but D_{2h} -symmetrical analogues fall in the range 2.85-3.06 Å in (H₂aep)₄[V₁₆Sb₄O₄₂]· $2H_2O_{185}^{185} 2.92-3.03 \text{ Å in } [V_{16}Sb_4O_{42}(H_2O)\{VO(dach)_2\}_4] \cdot (dach)$ $10H_2O_1^{187}$ and $2.92-3.05 \text{ Å in } [Zn_2(dien)_3][\{Zn(dien)\}_2V_{16}Sb_4O_{42}-V_{1$ (H_2O)] $4H_2O$. The "fully-reduced" $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanion with its new pseudorhombicuboctahedral topology is a component of the $[Zn(tren)(H_2tren)]_2[V_{16}Sb_4O_{42}(H_2O)] \cdot nH_2O$ compound (n = 6-10) obtained under solvothermal conditions (Table 4). Two trigonal bipyramidal $\{Zn(tren)(H_2tren)\}^{4+}$ complexes assume the role of countercations. The crystal structure of this compound that is soluble in methanol and ethanol contains channels between the SbPOVs arranged in the pairs by weak intercluster Sb...O interactions because of the specific orientation of the handle-like [Sb2O5]4- groups. The intermolecular N-H···O hydrogen bonds between the cations, polyoxoanions and

Fig. 28 (a and b) Segments of the 1D infinite linear (a) and zig-zag (b) chains in the crystal structures of $[Zn_2(dien)]_2V_{16}Sb_4O_{42}(H_2O)]\cdot 4H_2O$ and $[Zn(dien)_2]_2[\{Zn(dien)\}_2(V_14Sb_8O_{42})_2(H_2O)]\cdot 4H_2O$. Fig. 29 The "fully-reduced" $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanions featuring $\{V_{16}\}$ skeletons with different symmetries (D_{2h} and C_2). Colour code: Sb, dark yellow; O, red; V^{IV}, sky blue; V^{IV}O_x, sky-blue polyhedra.

H₂O molecules expand the structure of [Zn(tren)(H₂tren)]₂-[V₁₆Sb₄O₄₂(H₂O)]·nH₂O into a 3D network. The low-field magnetic susceptibility studies revealed that the C_2 -symmetrical [H₂O@V^{IV}₁₆Sb₄O₄₂]⁸⁻ polyoxoanion exhibits strong antiferromagnetic coupling between the spin-1/2 vanadyl {VO}²⁺ moieties. Remarkably, a significant difference in the susceptibility data was found between the compounds [Zn(tren)(H2tren)]2[V16Sb4O42- (H_2O)]- nH_2O (with C_2 -symmetrical $\{V_{16}\}$ spin polytope) and $[Zn_2(dien)_3][\{Zn(dien)\}_2V_{16}As_4O_{42}(H_2O)]\cdot 3H_2O^{159} \quad \text{(with} \quad \textit{D_{2}} h^{-1}) = 0$ symmetrical $\{V_{16}\}$ spin polytope), thus showing the effect of the pnictogen oxide positions on the magnetism of the isonuclear, but not isostructural AsPOV and SbPOV structures.

Cobalt- and nickel-SbPOV hybrids. The compound [{Co(en)₂}₂-V₁₄Sb₈O₄₂(H₂O)]·6H₂O prepared under hydrothermal conditions (Table 4) was the first example of functionalisation of a POV building block with antimony. 191 The crystal structure features 2D arrays of the spherical β -[H₂O@V^{IV}₁₄Sb₈O₄₂]⁴⁻ polyoxoanions that are joined through the covalent bonds between the apical oxygen atoms of the β-SbPOVs and the bridging Co²⁺ ions of the $[Co(en)_2]^{2+}$ complexes (Fig. 28c). Similar to the β - $[V_{14}^{IV}As_8O_{42}]^{4-}$ polyoxoanion (Fig. 15b), this "fully-reduced" SbPOV represents a modified $[V_{18}O_{42}]^{12-}$ structure whose four $\{VO_5\}$ square pyramids are replaced by four handle-like {Sb₂O₅} groups.

The compounds $[Co(tren)(H_2O)]_3[V_{15}Sb_6O_{42}(H_2O)]\cdot H_2O$, $[Co_2(tren)_3]_2[Co(tren)(en)][\{V_{15}Sb_6O_{42}(H_2O)(Co(tren)_2)\}V_{15}Sb_6O_{42}-V_{15}(H_2O)(Co(tren)_2)\}V_{15}Sb_6O_{42}-V_{15}(H_2O)(Co(tren)_2)]$ (H_2O)]- nH_2O ($n \approx 11$), and $[Co(tren)(H_2tren)]_2[V_{16}Sb_4O_{42}(H_2O)]$ -6H₂O containing distinct Co²⁺ complexes, namely [Co(tren)- $(H_2O)^{2+}$, $[Co_2(tren)_3]^{4+}$, $[Co(tren)(en)]^{2+}$, $[Co(tren)_2]^{2+}$, and [Co(tren)(H₂tren)]⁴⁺ were synthesised under solvothermal conditions using different concentrations of amine molecules (Table 4).192 Notably, the solvothermal reaction yielding $[Co_2(tren)_3]_2[Co(tren)(en)][\{V_{15}Sb_6O_{42}(H_2O)(Co(tren)_2)\}V_{15}Sb_6O_{42}-V_{15}(H_2O)(Co(tren)_2)\}V_{15}Sb_6O_{42}-V_{15}(H_2O)(Co(tren)_2)]$ (H₂O)]·nH₂O included a partial decomposition of tren molecules yielding bidentate en ligands. The inorganic-organic hybrid solids presented above are based on the [H₂O@V^{IV}₁₅Sb₆O₄₂]⁶⁻ or $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyoxoanions with diameters of ca. 11 Å. The "fully-reduced" SbPOV shells with the shortest V···V distances of 2.81-3.07 Å are derived from the $\{V_{18}O_{42}\}$ shell showing D_{4d} symmetry, i.e. 3 $\{VO_5\} \leftrightarrow 3 \{Sb_2O_5\}$. The $[H_2O@$ V₁₅^{IV}Sb₆O₄₂]⁶⁻ polyoxoanion in the crystal structure of [Co(tren)- (H_2O) ₃ $[V_{15}Sb_6O_{42}(H_2O)]\cdot H_2O$ are involved in weak Sb···O intercluster interactions, with the shortest one being ca. 2.90 Å. These Sb...O interactions are comparable with those identified e.g., in the 2D layered structures of the compounds (H₂en)₂[V^{IV}₁₄Sb₈- $O_{42}(H_2O)$]·3 H_2O ($d_{Sb\cdots O} = 2.72-2.92$ Å) and $(H_2ppz)_2[V_{14}^{IV}Sb_8-V_{14}^{I$ $O_{42}(H_2O)$] ($d_{Sb\cdots O}$ = 2.83–3.01 Å) with the discrete β -isomeric SbPOV motifs ($d_{V\cdots V}$ = 2.90- 3.10 Å). The solvothermal formation of these compounds is accompanied by a decomposition of N,N,N',N'-tetramethylethylenediamine to ethylenediamine and in situ fragmentation of 1-methylpiperazine to piperazine, respectively. Like for the compounds (H₂en)₂[V₁₄Sb₈O₄₂(H₂O)]- $3H_2O$ and $(H_2ppz)_2[V_{14}Sb_8O_{42}(H_2O)]$, $O_{SbPOV} \cdot \cdot \cdot H_{amine}$ hydrogen bonds are observed in the crystal structure of [Co(tren)(H₂O)]₃- $[V_{15}Sb_6O_{42}(H_2O)]\cdot H_2O$. The crystal structure of $[Co_2(tren)_3]_2$ - $[Co(tren)(en)][\{V_{15}Sb_6O_{42}(H_2O)(Co(tren)_2)\}V_{15}Sb_6O_{42}(H_2O)]\cdot nH_2O$ $(n \approx 11)$ is characterised by short Sb···N interactions (2.60 Å, 2.65 Å, and 2.74 Å), which engage the N atoms of primary amine molecules (tren) and the Sb atoms of the SbPOVs. Relatively short Sb···O intercluster contacts (2.88-2.93 Å) were also observed. The observed N-H···O hydrogen bonds generate a 3D network. Interestingly, the central $[H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-}$ polyanion of the compound [Co(tren)(H₂tren)]₂[V₁₆Sb₄O₄₂(H₂O)]·6H₂O is isostructural to that of $[Zn(tren)(H_2tren)]_2[V_{16}Sb_4O_{42}(H_2O)] \cdot nH_2O$ $(n = 6-10)^{190}$ (see Fig. 29) and can be viewed as being derived from the T_d -symmetric $\{V_{18}O_{42}\}$ shell, *i.e.* by formal metathesis $2{VO_5} \leftrightarrow 2{Sb_2O_5}$. The shortest $V \cdots V$ distances in this C_2 symmetrical SbPOV polyoxoanion are in the range 2.73-3.09 Å.

The compounds $[Co(aepda)_2]_2[\{Co(aepda)_2\}V_{15}Sb_6O_{42}(H_2O)]$ $5H_2O$ and $[Ni(aepda)_2]_2[\{Ni(aepda)_2\}V_{15}Sb_6O_{42}(H_2O)]\cdot 8H_2O$ (aepda = N-(2-aminoethyl)-1,3-propanediamine = $C_5H_{15}N_3$) were also obtained under solvothermal conditions 194 (Table 4) and their crystal structures feature the [H₂O@V₁₅Sb₆O₄₂]⁶⁻ polyoxoanion being structurally related to the well-known {V18O42} archetype, as is the case for the AsPOV analogue $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$. Each of these [H₂O@V₁₅^{IV}Sb₆O₄₂]⁶⁻ polyoxoanions comprises a terminal oxygen position covalently bonded to the transition metal complexes $[M(aepda)_2]^{2+}$ (M = Co, Ni). As a result, the M²⁺ centre has an octahedral M(N_{aepda})₅O_{SbPOV} coordination environment. The two remaining [M(aepda)₂]²⁺ moieties in each compound serve as charge-balancing cations. As in the case of several other TMC-functionalised heteroPOVs, the paramagnetic M2+ ions (M = Co, Ni) from the terminally coordinated [M(aepda)₂]²⁺ complexes couple only very weakly with the spin-1/2 vanadyl $\{VO\}^{2+}$ moieties of the $[H_2O@V_{15}^{IV}Sb_6O_{42}]^{6-}$ polyoxoanions. In the crystal structure of the compound comprising Co²⁺ ions, the polyoxoanions are connected through weak intercluster Sb···O (3.13 Å) interaction, thus forming pairs of SbPOVs (Fig. 28d). In contrast, in the crystal structure of the compound containing Ni²⁺ ions pairs of SbPOVs linked by weak Sb···N contacts (2.65 Å) are observed. These Sb···N interactions involve the Sb atoms of the "fully-reduced" [H2O@VISb6O42]6polyoxoanion and the N atoms of the propylamine chains from the adjoined [Ni(aepda)₂]²⁺ fragments (Fig. 28e). In addition,

intermolecular N–H \cdots O hydrogen bonds generating higher dimensional networks were observed in the structures of both these compounds.

A dimeric $\{[Ni_2(tren)_3(V_{15}Sb_6O_{42}(H_2O)_{0.5})]_2\}^{4-}$ fragment where two "fully-reduced" $[V_{15}^{IV}Sb_6O_{42}(H_2O)_{0.5}]^{6-}$ polyoxoanions (shortest $d_{V...V} = 2.84 - 3.08 \text{ Å}$) are bridged by an *in situ*-produced $[Ni_2(tren)_3]^{4+}$ complex *via* a multidentate μ -1,7 tren ligand was identified in the solvothermally synthesised, highly insoluble compound $[Ni(Htren)_2][Ni_2(tren)_3(V_{15}Sb_6O_{42}(H_2O)_{0.5})]_2 \cdot H_2O$ (Table 4). 195 Its crystal structure is characterised by double chains along the crystallographic b axis, formed by short Sb···N contacts $(d_{Sb\cdots N} = ca. 2.69 \text{ Å})$ between the neighbouring heterometallic dimers. Again, an additional [Ni(Htren)₂]⁴⁺ complex with protonated tren ligands acts as countercation. For comparison, the covalent Sb-N distances in the structures of the compounds $[V_{14}Sb_8(Haep)_4O_{42}(H_2O)]\cdot 4H_2O$ aforementioned and $(H_2aep)_2[V_{15}Sb_6(Haep)_2O_{42}(H_2O)]\cdot 2.5H_2O$ (Fig. 27) are $d_{Sb-N} =$ 2.53 and 2.54 Å and $d_{\rm Sb-N}$ = 2.50 and 2.54 Å, respectively. ¹⁸⁸ A 3D network in the crystal structure of [Ni₂(tren)₃(V₁₅Sb₆O₄₂- $(H_2O)_{0.5}$]₂[Ni(Htren)₂]·H₂O is generated by a complex hydrogen bonding pattern between H atoms of water molecules and the amine moieties and oxygen atoms of the SbPOVs.

Two pseudopolymorphic compounds with compositions $[Ni(dien)_2]_3[V_{15}Sb_6O_{42}(H_2O)] \cdot nH_2O$ (n = 12 and 8) and the compound [Ni(dien)₂]₄[V₁₆Sb₄O₄₂(H₂O)] were prepared solvothermally by adjusting the reaction temperature (Table 4). 196 The pseudopolymorphs display the spherical $[H_2O@V_{15}^{IV}Sb_6O_{42}]^{6-}$ polyoxoanions which are virtually isostructural to the molecular magnet $[H_2O@V_{15}^{IV}As_6O_{42}]^{6-}$. The structural motif of the "fullyreduced" $[V_{15}^{IV}Sb_6O_{42}]^{6-}$ polyoxoanion is shown in Fig. 25a and that of $[V_{16}^{IV}Sb_4O_{42}]^{8-}$, a component of the compound [Ni(dien)₂]₄[V₁₆Sb₄O₄₂(H₂O)], is illustrated in Fig. 26. Interestingly, the crystal structures of the pseudopolymorphs possess different composition of the asymmetric units that involve four crystallographically independent [H₂O@V^{IV}₁₅Sb₆O₄₂]⁶⁻ polyoxoanions and twelve [Ni(dien)2]2+ complexes adopting the s-fac, mer-, and u-fac-configurations (tetragonal space group) or a third of the polyoxoanion and a mer-{Ni(dien)₂}²⁺ complex (rhombohedral space group). In the crystal structure of the compound crystallising in the tetragonal space group, the SbPOVs are arranged as tetrameric superstructures with composition $([H_2O@V_{15}^{IV}Sb_6O_{42}]^{6-})_4$ (layer-like arrangement). The individual polyoxoanions are held together by weak Sb···O interactions (2.68 to 2.97 Å), which are significantly shorter than the sum of van der Waals radii (3.52 Å) for Sb and O atoms. For the structure crystallising in the rhombohedral space group, the shortest intercluster Sb···O distances exceed 5 Å, because of a triangular-like arrangement of dicationic mer-[Ni(dien)₂]²⁺ complexes around the $[V_{15}^{IV}Sb_6O_{42}]^{6-}$ polyoxoanions. The 3D network structure of this compound is realised by intermolecular N-H···O hydrogen bonding interactions. The compound $[Ni(dien)_2]_4[V_{16}Sb_4O_{42}(H_2O)]$ comprises octahedrally coordinated Ni2+ ions in the [Ni(dien)2]2+ cations adopting the s-fac- and u-fac-configurations. In the crystal structure of $[Ni(dien)_2]_4[V_{16}Sb_4O_{42}(H_2O)], \text{ the } [H_2O@V_{16}^{IV}Sb_4O_{42}]^{8-} \text{ polyoxo-}$ anions are arranged in layers in the (100) plane.

Iron-SbPOV hybrids. The solvothermally synthesised compound $[{Fe(dach)_2}_3{V_{15}Sb_6O_{42}(H_2O)}].8H_2O$ with the unique porous 3D network topology in its extended solid-state structure (Fig. 30) is the first example of an iron-augmented SbPOV architecture also exhibiting a unique magnetic structure. 197 The amine molecules used in the synthesis of this compound (Table 4) were shown to carry out versatile functions, acting as ligands, solvents, and reducing agents. In the structure, the $[H_2O@V_{15}^{IV}Sb_6O_{42}]^{6-}$ polyoxoanion is expanded by six in situgenerated [Fe(dach)₂]²⁺ complexes, which coordinate terminally to the polyoxoanion via Fe-O bonds to form octahedral {FeN₄O₂} units that further interlink the adjoined SbPOVs. Relatively strong N-H···O hydrogen bonds were observed. The compound is further characterised by an optical energy gap of 2.47 eV. The low-field magnetic susceptibility revealed ferromagnetic exchange interactions between the spin-1/2 vanadyl {VO}2+ moieties of the polyoxoanion and the highspin (S = 2) Fe²⁺ ions of the adjoined [Fe(dach)₂]²⁺ complexes. We note that this heterometal-vanadyl coupling differs significantly from that established for the aforementioned TMCsupported AsPOVs and SbPOVs, which showed only weak or negligible, and mostly antiferromagnetic interactions between the spin centres of the central building blocks and the attached TMC fragments.

3.3.5 Corollary for SbPOVs. All hitherto reported SbPOVs are based on the $\{V_{14}\}$ -, $\{V_{15}\}$ -, and $\{V_{16}\}$ -type skeletons composed exclusively of V^{IV} ions. The different symmetries of these "fully-reduced" SbPOVs were determined as D_{2d} for $\alpha - \left[V_{14}^{IV}Sb_{8}O_{42}\right]^{4-}, \; D_{2h} \; \; \text{for} \; \; \beta - \left[V_{14}^{IV}Sb_{8}O_{42}\right]^{4-}, \; D_{3} \; \; \text{for} \; \left[V_{15}^{IV}Sb_{6}O_{42}\right]^{6-},$ and D_{2h} and C_2 for $[V_{16}^{IV}Sb_4O_{42}]^{8-}$. No mixed-valent SbPOVs have yet been reported. The SbPOV-based compounds display 1D, 2D and 3D solid-state structures where the polyoxoanions were found to form weak intercluster Sb. . . O and/or Sb. . . N interactions. On one hand, the SbPOVs exhibit interesting reactivity towards the covalent attachment of organic amines, which can reduce or fully balance the high negative molecular charge of the polyoxoanion shell. On the other hand, the SbPOVs also allow for functionalization with transition metal complexes to generate TMC-supported SbPOV structures, which are of considerable interest due to the addition of multiple spin centres with different magnetic moments. The possible influence of these adjoined TMC fragments on the spin (de)coherence in

Fig. 30 3D network in the crystal structure of [{Fe(dach) $_2$ } $_3$ {V $_{15}$ Sb $_6$ O $_{42}$ -(H $_2$ O)]}-8H $_2$ O. The channels along [-110] are shown. Crystal solvent (water) molecules are omitted for clarity.

SbPOVs with an odd number of V^{IV} atoms (and spin-1/2 ground states) remains as an interesting problem. S = 0 ground states were established for the $\{V_{14}\}$ - and $\{V_{16}\}$ -nuclearity building blocks with the even number of V^{IV} atoms.

The study of the chemical and physical properties and reactivity of the SbPOVs has been motivated, in particular, by the following points closely related to catalysis:

- (i) The Sb^{III} ions exhibited stabilising effects on the Keggintype POM structures at high temperatures (>450 °C) and this played an important role in employing the Sb-modified POMs as catalysts, e.g. for the oxidative dehydrogenation of ethane to ethylene.198
- (ii) Since Sb-modified vanadium catalysts were shown to selectively oxidise o-xylene to phthalic anhydride, 199 SbPOVs might find potential applications as pre- or catalysts in heterogeneous selective oxidation reactions.

4. Summary and outlook

We reviewed the structural aspects and key properties of heavier group 14 and 15 element-functionalised POVs and their inorganic-organic hybrid compounds involving transition metal and lanthanoid complexes as charge compensating units and structure modifiers. We provided an overview of the synthetic routes to SiPOVs, GePOVs, AsPOVs and SbPOVs whose central structural motifs typically are derived from the {V18O42} archetype and display rhombicuboctahedral topologies. The V⁴⁺ cations in these robust polyoxoanions incorporating handle-like $\{E_2O_7\}/\{E_2O_5S_2\}$ (E = Si or Ge) and $\{E_2O_5\}$ (E = As or Sb) groups adopt the very common square-pyramidal {VO₅} coordination geometry, although a number of compounds involving {VO₆} octahedra and {VO₄} tetrahedra were also reported. Note that the crystal chemical aspects of vanadium oxide polyhedra were comprehensively analysed by Schindler et al., in 2000²⁰⁰ and were, therefore, not discussed herein. The topological aspects of POV macropolyhedra can be found in the work of King dating back to 1995.201

It was shown that the $\{Ge_2O_5S_2\}$ and $\{As_2O_5\}/\{Sb_2O_5\}$ substituents in the $\{V_{15}E_6\}$ -type building blocks play crucial roles in superexchange interactions within the central spin-1/2 {V₃} triangle that define the low-temperature magnetism of these heteroPOVs. Even though the $[H_2O@V_{15}Ge_6O_{42}S_6]^{12-102}$ and [V₁₅Sb₆O₄₂]⁶⁻¹⁸⁶ polyoxoanions feature spin topologies very similar to that of the prominent molecular magnet [H₂O@V₁₅As₆O₄₂]⁶⁻, ¹⁵¹ the magnetic exchange properties of the {Ge₂O₅S₂}-modified POVs differed significantly from those of the corresponding As- and Sb-functionalised POVs.

As was demonstrated by a large number of studies, the discrete heteroPOVs can be extended further towards the hybrid inorganic-organic frameworks by introducing TMCs or lanthanoid salts to the reactions mixtures. These TMCs and lanthanoid complex cations commonly act as bridging ligands between the neighbouring heteroPOVs and often exhibit unusual coordination geometries and connectivities. The transition metal ions (Mn²⁺, Fe²⁺, Co²⁺, Ni²⁺, Cu²⁺, Zn²⁺, Cd²⁺) can be

introduced into the backbone structures of the vanadium oxide shells to facilitate the linking of these heteroPOVs into 1D, 2D and 3D networks and to enrich/modify their magnetic properties. We did not highlight the structural chemistry of TMC fragments in these structures; discussion on their coordination geometries and bonding patterns can be found in the original literature. The use of adjoined inorganic moieties (e.g. lanthanoid complex cations¹⁵⁰) was shown to result in high coordination numbers (up to 6) for the POV shells and, thus, to remarkably increase the overall thermal stabilities of these heteroPOV-based materials (even exceeding 500 °C). The transition metal functionalisation of the polynuclear molecular vanadium oxides open up new possibilities for making new heteroPOV spin architectures with e.g. spin-glass behaviour by virtue of the fact that the vanadyl {VO}²⁺ moieties in these polyoxoanions can be replaced by divalent transition metal ions.

Another way to improve the thermal stability of heteroPOVs may be through the preparation of heteroPOV-based ionic liquids, which can be achieved by pairing negatively charged heteroPOV building blocks with appropriate cations such as imidazolium, pyridinium, phosphonium species. For instance, a number of Keggin and Lindqvist polyoxomolybdate and polyoxotungstate-based ionic liquids²⁰² and tetraalkylphosphonium decavanadates²⁰³ have been reported.

The reactivity of heteroPOVs towards organic groups was also illustrated. The organic amines usually introduced in the reaction mixtures are commonly not only acting as reducing agents, but also as structure-directing and charge-compensating groups and, furthermore, display interesting transformations under hydro-/solvothermal conditions in the presence of VV sources. The organic functionalisation of magnetic polyoxoanions, as exemplified by [H₂O@V^{IV}₁₄Sb₈(Haep)₄O₄₂] and [H₂O@ $V_{15}^{IV}Sb_6(Haep)_2O_{42}]^{4-,188}$ enabled their dissolution in polar protic solvents (methanol, ethanol, etc.). It also can partly or fully compensate the high negative charges of the heteroPOVs, an important issue for molecular deposition and subsequent (micro)spectroscopic studies with this class of compounds. Such a direct covalent attachment of organic ligands allows for the expansion of heteroPOVs into classical coordination clusters and may significantly influence their redox and acidbase properties.204

The relevance of the presented polyoxoanions to different fields of chemical and physical sciences was briefly discussed. The heteroPOVs are envisaged to find potential applications in molecular electronics and spintronics, optics, sorption, catalysis and artificial photosynthesis.205 However, the search for heteroPOV compounds with sufficient solubility in organic solvents and a high structural and thermal stability is crucial in this context. The synthesis of new discrete and multidimensional SiPOVs, GePOVs, AsPOVs and SbPOVs is highly desirable in order to discover strategies for altering their chemical and physical properties.

Since the ratio of VV/VIV and VIV/VIII redox couples and molecular connectivities are strongly influenced by the nature of the heteroelements, and since the overall E/VV/VIV/VIII ratio impacts the overall properties of the heteroPOV to a large Review Article Chem Soc Rev

extent, the chemical modification of the conventional POV shells by heavier metal ions from groups 14 such as Sn and Pb is appealing and worthwhile. For example, functionalisation of POVs with bismuth, the heaviest group-15 element, resulted in interesting photocatalytic activity of the designed molecular bismuth vanadium oxide clusters. 206 The reactivities of SiPOVs, GePOVs, AsPOVs and SbPOVs towards transition metals e.g. from the platinum group and actinoids are yet to be discovered. Integration of lanthanoid ions into heteroPOV shells may lead to interesting magnetic phenomena as well as visible-light photocatalytic properties. The controlled interlinking of hetero-POV spin structures is of high importance for the development of smart materials with electron storage functions and intersite communications. The coexistence of (partly) delocalised 3d-vanadium electron density with localised spins of transition metals and lanthanoids in the mixed-valent heteroPOV-based inorganic-organic hybrid materials may result in unusual spintronic effects, "in particular, if the corresponding charge transport can be confined to one or two dimensions". 114

The molecular magnetism of heteroPOVs described so far is characterised by the presence of strong antiferromagnetic exchange interactions between the vanadium spin centres, with the exception of several compounds showing ferrimagnetic ordering characteristics. Because there are some indications of ferromagnetic coupling interactions in heteroPOVs (see the mixed-valent $[HCO_2@V_6^{IV}V_6^VAs_8O_{40}]^{3-}$ polyoxoanion^{119,120}) as well as alkoxoPOVs (see the mixed-valent [V₄^{IV}V₂^VO₇(OR)₁₂] compound⁷⁸ and the mixed-valent [V^{III}V₅^{IV}O₆(OMe)₈(calix)(MeOH)]⁻ polyoxoanion²⁰⁷ where calix = p-tert-butylcalix[4]arene), the magnetic properties of these compounds should be explored in more detail. Building a deeper understanding of the magnetism of the mixed-valent, "fully-reduced" and "highly-reduced" SiPOVs, GePOVs, AsPOVs and SbPOVs, which can potentially act as "nanoscale quantum magnets" and spin qubits remains challenging, because of the absence of magnetochemical models suitable for the fitting of their magnetic susceptibility data.

Only a few studies have employed quantum chemical models to study the electronic structures of fully-oxidised POVs 208 and of some of the herein-described "fully-reduced", semimetal-functionalised POVs with the V_{14} and V_{15} nuclearities. 209 Reliable computational methods for assessing the electronic and magnetic properties of the mixed-valent heteroPOVs are still being developed.

The biological and medicinal relevance of POVs²¹⁰ deserves mention, as the archetypal decavanadate $[V_{10}O_{28}]^{6-}$ has demonstrated non-trivial chemical behaviour and reactivity towards biomolecules,²¹¹ *e.g.*: (i) inhibition of various enzymes,²¹² (ii) hydrolytic DNA cleavage,²¹³ (iii) inhibition of oxygen consumption in membranes.²¹⁴ The interactions of other, lower nuclearity, but more labile oxovanadates $([VO_4]^{3-}$ as a structural and electronic analogue of phosphate, $[V_2O_7]^{4-}$, and $[V_4O_{12}]^{4-}$) with enzymes²¹⁵ have also been recognised and well-documented.^{1,216} Over the past two decades, much attention has been paid to biochemical, cell biological, antidiabetic and antitumor studies involving vanadium^{217–219} and organic biomolecules for the reason that "understanding the nature of protein interactions with

oxovanadates and other oxometalates is important for further development of drugs based on vanadium complexes and polyoxoanions". In view of the biological innocuity of bismuth and its extensive uses in medicine, pharmaceuticals, and cosmetics, the class of polyoxovanadatobismuthates is relevant to biochemical studies.

Although the number of reports on magnetic heteroPOVs has grown substantially in the last few decades, the field is hampered by the lack of systematic research on this class of molecular compounds. Many questions concerning their inorganic synthesis, reactivity in aqueous and non-aqueous solutions, molecular magnetism, spectroscopy (in particular, NMR studies in solution and in the solid state), excited states and computational application remain entirely open. The benefits of effective adjustment of the heteroPOV building block's properties from the standpoint of chemical reactivity, electrochemistry, molecular magnetism, photophysics and surface physics will be remarkable.

Finally, we note that the self-assembly formation mechanisms of heteroPOVs remain poorly understood and for the development of rational syntheses these mechanisms should be unveiled. There are first promising attempts in this direction: in situ energy-dispersive X-ray diffraction experiments were performed under hydrothermal conditions in order to gain insight into the synthetic parameters influencing the formation of SbPOVs.²²⁰ These studies were able to demonstrate directly that e.g. the amine concentration plays a crucial role for the crystallisation of a distinct SbPOV, where the formation of $[V_{14}Sb_8(Haep)_4O_{42}(H_2O)]\cdot 4H_2O^{188}$ is observed at the lowest amine concentration, whereas (H₂aep)₂[V₁₅Sb₆(Haep)₂O₄₂(H₂O)]-2.5H₂O¹⁸⁸ crystallised at slightly larger amine concentration and finally the SbPOV with the highest number of VIV centres, (H₂aep)₄[V₁₆Sb₄O₄₂]·2H₂O₂, was obtained at the highest amine concentration. In addition, solvothermal syntheses performed under static conditions yield mixtures of these three SbPOVs while stirring afforded formation of phase pure materials at a distinct amount of amine in the reaction slurries. These empirical in situ studies pave the way for a more comprehensive understanding of the complex self-assembly processes in vanadate reaction solutions, in line with similarly revealing in situ spectroscopy studies in the chemistry of other polyoxometalate families.221
