## Te–Te and Te–C bond cleavage reactions using a monovalent gallanediyl†

Chelladurai Ganesamoorthy, Georg Bendt, Dieter Bläser, Christoph Wölper and Stephan Schulz\*

LGa (L = [(2,6-*i*-Pr<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>)NC(Me)]<sub>2</sub>CH) reacts with elemental tellurium with formation of the Te-bridged compound [LGa-μ-Te]<sub>2</sub> **1**, whereas the reactions with Ph<sub>2</sub>Te<sub>2</sub> and *i*-Pr<sub>2</sub>Te occurred with cleavage of the Te–Te and Te–C bond, respectively, and subsequent formation of LGa(TePh)<sub>2</sub> **2** and LGa(*i*-Pr)Te-*i*-Pr **3**. **1–3** were characterized by heteronuclear NMR (<sup>1</sup>H, <sup>13</sup>C, <sup>125</sup>Te) and IR spectroscopy and their solid state structures were determined by single crystal X-ray analyses.

### Introduction

Univalent LGa containing the sterically crowded β-diketiminato ligand (L = [(2,6-*i*-Pr<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>)NC(Me)]<sub>2</sub>CH)<sup>1</sup> adopts a monomeric structure in the solid state and in solution. The gallium valence shell contains two bond pairs, a lone pair and an empty p-orbital. Therefore, LGa can react as electrophilic and nucleophilic reagent at the gallium atom. Computational calculations predicted that LGa is a good σ-donor but a poor π-acceptor due to the low energy and high s-character of the HOMO, and the large energy difference (95.3–110 kcal mol<sup>-1</sup>) between the HOMO and the rather diffuse acceptor 4p-orbital (LUMO+1).<sup>2–4</sup> The σ-donor capacity of LGa was experimentally demonstrated for instance with the synthesis of the Lewis acid–base adduct LGa→B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub><sup>5</sup> and other p- or d-block metal complexes as well as with the synthesis of a large variety of (late) transition metal complexes.<sup>6</sup> The latter were shown to be promising reagents for the activation of small molecules such as ethylene and have been used as precursors for the formation of heterometallic clusters,<sup>7,8</sup> which in part can be described as molecular models for alloys.

While the coordination chemistry of LGa has been developed to a far greater extent compared to that of its lighter homologue LAl, its use in the transformation of unsaturated organic substrates has not,<sup>9–11</sup> which most likely results from the weaker reducing properties of LGa. However, LGa was found to react with E–X bonds *via* insertion of the Ga(I) centre

and subsequent formation of covalent Ga–E bonds.<sup>12</sup> This reaction pathway was used for cluster formation reactions *via* oxidative insertion/reductive elimination processes. The synthesis of molecular gallium–tin intermetallic clusters upon reaction of LGa with SnCl<sub>2</sub><sup>13</sup> as well as two galla-dibismuthenes containing covalent Ga–Bi single-bonds and Bi=Bi double bonds, which were obtained from the reactions of LGa with Bi(OR)<sub>3</sub> (R = O<sub>2</sub>SCF<sub>3</sub>, C<sub>6</sub>F<sub>5</sub>),<sup>14</sup> represent remarkable experimental “snapshots” of these reactions. The cluster compounds can be considered as isolated reaction intermediates on the way to full reduction to tin metal and bismuth metal, respectively. The syntheses of these complexes demonstrate the promising potential of LGa to serve as selective reducing agent in the preparation of metalloid clusters and subvalent “metastable” compounds.

In addition to these interesting studies on the synthesis of intermetallic compounds, the capability of LGa in bond activation reactions was also studied. LGa was reacted with a large variety of compounds containing different element–element bonds including dihydrogen<sup>15</sup> as well as electronically unsaturated molecules such as N<sub>2</sub>O, organic azides N<sub>3</sub>R and elemental sulphur. Many of these reactions were performed in order to synthesize compounds containing multiple bonds to gallium. However, reactions of LGa with N<sub>2</sub>O or S<sub>8</sub> yielded the oxo- or sulfido bridged dimers [LGa-μ-E]<sub>2</sub> (E = O, S),<sup>16</sup> while its reaction with N<sub>3</sub>SiMe<sub>3</sub> proceeded with formation of a cyclic gallium tetrazole and a gallium imide/azide compound. The most-likely formed reaction intermediate, a monomeric gallium imide LGa=NR,<sup>17</sup> was finally synthesized by reaction of LGa with the sterically encumbered azide Ar<sup>\*</sup>N<sub>3</sub> (Ar<sup>\*</sup> = 2,6-Trip<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>, Trip = 2,4,6-*i*-Pr<sub>3</sub>-C<sub>6</sub>H<sub>2</sub>) and structurally characterized by single crystal X-ray diffraction.<sup>18</sup>

Our long-term interest in the reactivity of low-valent organometallics of group 12 to 16 elements prompted us to start investigations on the general reactivity of LM (M = Al, Ga, In)

toward group 15 compounds such as  $\text{BiEt}_3$ <sup>19</sup> as well as tetraalkyldistibanes and dibismuthanes  $\text{Et}_4\text{E}_2$  (E = Sb, Bi).<sup>20</sup> These reactions were found to proceed with cleavage of the Bi–C as well as E–E bond and subsequent formation of  $\text{LM}(\text{Et})\text{BiEt}_2$  and  $\text{LM}(\text{EEt}_2)_2$ , respectively, in which the Ga atom is oxidized from the formal oxidation state +I to +III. Moreover, oxidative addition reactions of monovalent Zn(I) compounds,<sup>21</sup> germylenes and stannylenes<sup>22</sup> as well as distibanes and dibismuthanes<sup>23</sup> with dichalcogenanes were reported by us. In addition, insertion reactions of elemental chalcogens into metal–metal bonds were observed in reactions with tetraalkyldistibanes and -dibismuthanes.<sup>24,25</sup> We herein report on the reactions of LGa with elemental tellurium as well as diphenylditellane  $\text{Ph}_2\text{Te}_2$  and diisopropyltellane  $i\text{-Pr}_2\text{Te}$ , which proceeded with Te–Te and Te–C bond cleavage and subsequent formation of compounds containing direct Ga–Te  $\sigma$ -bonds.

## Results and discussion

Equimolar amounts of LGa were reacted with elemental tellurium, diphenylditellane  $\text{Ph}_2\text{Te}_2$  and diisopropyltellane  $i\text{-Pr}_2\text{Te}$  in toluene at ambient temperature, yielding the Te-bridged dimer  $[\text{LGa}-\mu\text{-Te}]_2$  **1** as well as  $\text{LGa}(\text{TePh})_2$  **2** and  $\text{LGa}(i\text{-Pr})\text{Tei-Pr}$  **3**, respectively (Scheme 1). **1–3** are moisture sensitive, yellow to pale yellow crystalline solids but moderately stable toward air. **1** is sparingly soluble in benzene, toluene and *n*-hexane whereas **2** and **3** are soluble in these solvents.

The <sup>1</sup>H and <sup>13</sup>C NMR spectra of **1–3** show the characteristic resonances of the organic entities. <sup>1</sup>H NMR spectral pattern of **1** and **2** are similar to those of LGa and  $C_{2v}$  symmetric molecules related to the  $\beta$ -diketiminate ligands. They exhibit single resonances for the  $\gamma$ -CH (4.59 ppm, **1**; 4.76 ppm, **2**) and two methyl groups of the  $C_3N_2Ga$  rings (1.35 ppm **1**; 1.50 ppm **2**). The methyl protons of the isopropyl substituents and methine

protons appear as two doublets (1.13 & 1.10 ppm **1**; 1.48 & 1.08 ppm **2**) and a septet (3.33 ppm **1**; 3.62 ppm **2**), respectively. Due to its low solubility, the <sup>13</sup>C and <sup>125</sup>Te NMR resonances of **1** were not intense enough. The <sup>13</sup>C NMR spectrum of **2** shows 14 signals including the characteristic resonances due to the  $\gamma$ -CH (99.22 ppm) backbone carbon atom, both  $\beta$ -C atoms of the  $C_3N_2Ga$  ring (170.63 ppm) and the methine (29.36 ppm) and methyl carbon atoms of isopropyl groups (27.01, 25.44 ppm). Compound **3** shows more distinct <sup>1</sup>H and <sup>13</sup>C NMR patterns than **1** and **2**. Due to the presence of three different substituents at the Ga atom and a hindered rotation about the N–C bonds, the *i*-Pr groups in **3** are magnetically inequivalent, leading to six doublets (1.87, 1.61, 1.34, 1.31, 1.08, 0.67 ppm) in the <sup>1</sup>H NMR spectrum. The six methine protons of the *i*-Pr groups appear as four septets (4.16, 3.82, 3.42, 1.04 ppm) with the integral ratios of 2:1:2:1, respectively. Integrals of 2 H belong to the *i*-Pr methine groups of the L ligand. The  $\gamma$ -CH and two methyl groups of the  $C_3N_2M$  ring are in the mirror plane and exhibit only single resonances at 4.67 and 1.51 ppm, respectively. The <sup>13</sup>C{<sup>1</sup>H} NMR spectrum of **3** shows the expected 19 signals and some of them were tentatively assigned to the *i*-Pr carbons atoms in **3** in the Experimental section. Elemental analyses (C, H, N) of **1–3** confirm the structural compositions and their analytical pure nature. Furthermore, the NMR (<sup>1</sup>H, <sup>13</sup>C, <sup>125</sup>Te) and IR spectroscopic details are in accordance with the proposed formulations of **1–3**.

**1–3** are stable in solution and no reduction/decomposition occurs even at 90 °C in  $C_6D_6$ . Despite that the first Te–C bond cleavage of  $i\text{-Pr}_2\text{Te}$  occurred smoothly at room temperature, the second Te–C bond couldn't be cleaved by reaction with an additional equivalent of LGa. In contrast, we successfully cleaved the Te–C and Te–Te bonds of  $\text{Ph}_2\text{Te}_2$  upon reaction with an equimolar amount of the Lewis acid–base adduct  $\text{LGa} \rightarrow \text{B}(\text{C}_6\text{F}_5)_3$  in  $C_6D_6$ , which yielded a yellow-orange solution at room temperature within three days. The <sup>1</sup>H NMR spectrum of the reaction mixture shows the presence of four different types of  $\gamma$ -CH protons with different integral ratios (Fig. S11†) and the spectral comparison evidences the presence of traces of **1** (4.57, 3.39 ppm) and **2** (4.76, 3.62 ppm) along with two unknown compounds. Prolonged storage of the reaction mixture (10 days) at room temperature led to pale yellow crystals of **1**. During this period the peaks corresponding to **2** gradually decreased. Unfortunately, our efforts to isolate the major component of the reaction mixture (see Fig. S12†) failed since the solution is highly sensitive and decomposes to oily substances. According to the <sup>1</sup>H NMR pattern, the Ga atom in the major product has three different substituents.

Single crystals of **1** were grown separately in benzene and toluene solutions. **1a** is the solvent-free compound (obtained from the 1:1 reaction of  $\text{Ph}_2\text{Te}_2$  and  $\text{LGa} \rightarrow \text{B}(\text{C}_6\text{F}_5)_3$ ) and crystallises in the monoclinic space group  $P2_1/n$ , while **1b** is its toluene hemi-solvate (obtained from the 1:1 reaction of Te and LGa), which crystallises in the monoclinic space group  $C2/m$ . Single crystals of **2** were obtained from a freshly prepared *n*-hexane solution upon storage at room temperature,

{[Me<sub>3</sub>SiNC(Ph)C(SiMe<sub>3</sub>)<sub>2</sub>]Ga- $\mu$ -Te}<sub>2</sub> (2.570 Å)<sup>27</sup> and [i-Pr<sub>2</sub>PNP(i-Pr<sub>2</sub>)TeGa- $\mu$ -Te]<sub>2</sub> (2.5783(7) Å) as well as the six-membered heterocycle [i-Pr<sub>2</sub>PNP(i-Pr<sub>2</sub>)TeGa- $\mu$ -Te]<sub>3</sub> (2.582(2) Å).<sup>28</sup> In addition, the mixed Te/carboxylate-bridged compound [R<sub>2</sub>Ga<sub>2</sub>( $\mu$ -Te)( $\mu$ -OOCCH<sub>3</sub>)<sub>2</sub>] (2.534 Å)<sup>29</sup> as well as the base-stabilized compounds LGa(TePh)<sub>3</sub> (L = NMe<sub>3</sub>, PCy<sub>3</sub>), which were obtained from the reaction of base-stabilized gallanes [LGaH<sub>3</sub>] with Ph<sub>2</sub>Te<sub>2</sub> and which also contain fourfold-coordinated Ga atoms and twofold-coordinated Te atoms, show comparable Ga-Te bond distances of 2.580(1) Å and 2.597(2) Å, respectively.<sup>30</sup> In contrast, the Ga-Te bonds in the [MeGa(TePh)<sub>3</sub>]<sup>+</sup> monocation of [(Me<sub>3</sub>P)<sub>4</sub>Cu][MeGa(TePh)<sub>3</sub>] is slightly elongated (2.6406(3) Å).<sup>31</sup> The same holds for the Ga-Te bonds in four structurally characterized Ga<sub>4</sub>Te<sub>4</sub> heterocubanes, which range from 2.67 to 2.72 Å,<sup>32–35</sup> as well as in dimeric compounds of the general type [R<sub>2</sub>Ga- $\mu$ -TeR]<sub>2</sub>, for which Ga-Te bond lengths in the range from 2.67 to 2.76 Å were reported.<sup>36–39</sup> In contrast, slightly shorter Ga-Te bond lengths were reported for {[Me<sub>3</sub>Si)<sub>2</sub>CH]<sub>2</sub>Ga- $\mu$ -Te} (2.5521(4) Å),<sup>40</sup> [(Me<sub>3</sub>Si)<sub>2</sub>CH]<sub>2</sub>GaTeSi(SiMe<sub>3</sub>)<sub>3</sub> (2.535(1) Å),<sup>41</sup> whereas the Ga-Te bonds observed in Ga{TeSi(SiMe<sub>3</sub>)<sub>3</sub>}<sub>3</sub> (av. 2.496(6) Å)<sup>42</sup> as well as in Tp<sup>#</sup>GaTe (2.422(1)) (Tp<sup>#</sup> = tris(3,5-di-*tert*-butylpyrazolyl)hydroborato), to date the only compound containing a terminal Ga-Te double bond, are significantly shortened.<sup>43</sup>

Reactions of trivalent group 13 compounds (MR<sub>3</sub>, MH<sub>3</sub>; M = Al, Ga, In) with elemental chalcogens E or chalcogen

sources such as R<sub>3</sub>P=E (E = O, S, Se, Te) typically occur with insertion of the chalcogen atom into the M-C/H bond and subsequent formation of dimeric ([R<sub>2</sub>M- $\mu$ -ER]<sub>2</sub>) or tetrameric ([RME]<sub>4</sub>) compounds, whereas divalent (R<sub>4</sub>M<sub>2</sub>) as well as monovalent group 13 compounds RM (M = Al, Ga, In, Tl) react with insertion of the chalcogen atom into the M-M bond.<sup>44–49</sup> In addition, E-Br bond cleavage reactions of PhEBr (E = Se, Te) upon treatment with the monovalent In(i) cluster [(Me<sub>3</sub>Si)<sub>3</sub>C]<sub>4</sub>In<sub>4</sub><sup>50</sup> as well as of Te-Te bond cleavage reactions of Ph<sub>2</sub>Te<sub>2</sub> by reaction with Ga(i)<sup>26</sup> and In(i) compounds<sup>51</sup> as well as with base-stabilized GaH<sub>3</sub><sup>30</sup> were reported. However, to the best of our knowledge, the cleavage of the Te-C bond of diorganytellanes upon reaction with monovalent group 13 compounds RM has never been observed before.

## Conclusions

LGa was found to selectively insert into the Te-Te bond of diphenylditellane Ph<sub>2</sub>Te<sub>2</sub> as well as one Te-C bond of diisopropyltellane i-Pr<sub>2</sub>Te, resulting in the formation of LGa(TePh)<sub>2</sub> **2** and LGa(i-Pr)Tei-Pr **3**. Moreover, its reaction with elemental tellurium yielded the Te-bridged compound [LGa- $\mu$ -Te]<sub>2</sub> **1**. We are currently investigating reactions of the somewhat stronger reducing agent LAl with various group 16 precursors. A previous report showed that LAl reacted with elemental sulfur

with subsequent formation of  $[La(\mu-S_3)]_2$ , containing an unusual  $Al_2S_6$  ring.<sup>52</sup>

## Experimental

All manipulations were performed in an atmosphere of purified argon using standard Schlenk and glove-box techniques. Toluene and hexane were dried using a mBraun Solvent Purification System. THF was carefully dried over Na/K. Deuterated solvents were dried over activated molecular sieves (4 Å) and degassed prior to use. Anhydrous nature of the solvents was verified by Karl Fischer titration. The  $^1H$  (300 MHz),  $^{13}C\{^1H\}$  (75.5 MHz) and  $^{125}Te$  NMR (95 MHz) ( $\delta$  in ppm) spectra were recorded using a Bruker Avance DPX-300 spectrometer. The  $^1H$  and  $^{13}C\{^1H\}$  spectra were referenced to internal  $C_6D_5H$  ( $^1H$ :  $\delta$  = 7.154;  $^{13}C$ :  $\delta$  = 128.39) and  $C_6D_5CHD_2$  ( $^1H$ :  $\delta$  = 2.09;  $^{13}C$ :  $\delta$  = 20.40).  $^{125}Te$  NMR spectra were referenced to  $Na_2TeO_3$  in  $D_2O$ . The microanalyses were performed at the elemental analysis laboratory of the University of Duisburg-Essen. IR spectra were measured with an ALPHA-T FT-IR spectrometer equipped with a single reflection ATR sampling module. Elemental tellurium and  $Ph_2Te_2$  were commercially available and used as received, whereas  $i-Pr_2Te$  was freshly prepared according to a slightly modified procedure described for the synthesis of  $Te-(SiMe_3)_2$ .<sup>53</sup> In necessary cases, the reaction mixtures were filtered using a oven dried Teflon cannula (3.5 mm D) in which one end of the tip was wrapped with Whatman® glass micro-fiber filters (CAT no. 1823-025) using Teflon tape.

**Synthesis of  $i-Pr_2Te$ .**  $Et_3BHLi$  ("superhydride", 1.0 M in THF, 16.06 mmol, 16.1 mL) was added drop wise to a THF (50 mL) suspension of  $Te$  (1.0 g, 7.84 mmol) at 0 °C. After stirring at room temperature for 2 h, a solution of isopropyl bromide (1.976 g, 16.06 mmol, 1.5 mL) in THF (10 mL) was added. The reaction mixture was additionally stirred at room temperature for 2 h and the mixture was filtered through a glass frit. The solvents were removed under reduced pressure (500 mbar) and  $i-Pr_2Te$  was distilled at 45 °C (10 mbar). Yield: 72% (1.20 g).  $^1H$  NMR ( $C_6D_6$ , 300 MHz):  $\delta$  3.18 (sept,  $-CH(CH_3)_2$ , 2 H), 1.50 (d,  $-CH(CH_3)_2$ , 12 H).  $^{13}C$  NMR ( $C_6D_6$ , 75 MHz):  $\delta$  28.00 ( $-CH(CH_3)_2$ ), 10.57 ( $-CH(CH_3)_2$ ).

**Synthesis of **1**.** A mixture of elemental tellurium (0.0393 g, 0.308 mmol) and LGa (0.150 g, 0.308 mmol) in 20 mL of toluene was stirred at ambient temperature for 3 days. The reaction mixture was cannula filtered and the precipitate was extracted twice with 10 mL of hot toluene. Combined filtrates were concentrated to 10 mL and stored at  $-30$  °C for 3 days to afford analytically pure **1** as pale yellow crystals. Yield: 61% (0.115 g). Anal. Calcd for  $C_{58}H_{82}Ga_2N_4Te_2$ -toluene: C, 59.05; H, 6.86; N, 4.24. Found: C, 59.70; H, 6.89; N, 4.26%.  $^1H$  NMR (300 MHz, toluene- $d_8$ ):  $\delta$  7.10 (m,  $C_6H_3(^1Pr)_2$ , 12 H), 4.59 (s,  $\gamma-CH-$ , 2 H), 3.33 (sept,  $-CH(CH_3)_2$ , 8 H), 1.35 (s,  $ArNCCH_3$ , 12 H), 1.10 (br m,  $-CH(CH_3)_2$ , 48 H). IR (neat):  $\nu$  2961 (m), 2921 (w), 2859 (w), 1530 (s), 1438 (m), 1381 (s), 1307 (s), 1257

(m), 1177 (m), 1097 (w), 1018 (m), 938 (m), 859 (m), 796 (s), 757 (m), 723 (m), 688 (w), 638 (w), 532 (w), 461 (w)  $cm^{-1}$ .

**Synthesis of **2**.** A solution of  $Ph_2Te_2$  (0.168 g, 0.41 mmol) in toluene (2 mL) was added dropwise to a well-stirred toluene (2 mL) solution of LGa (0.2 g, 0.41 mmol). The reaction mixture was stirred at room temperature for 3 h to give a clear yellow solution. The solution was then concentrated to 1 mL, layered with 1 mL of  $n$ -hexane and stored at  $-30$  °C to give an analytically pure crystalline precipitate of **2**. Single crystals suitable for X-ray diffraction analysis were grown from  $n$ -hexane solution. 0.13 g of **2** was dissolved in 4 mL of warm  $n$ -hexane and stored at room temperature for 1 day to give yellow crystals suitable for X-ray diffraction analysis. Yield: 73% (0.269 g). Anal. Calcd for  $C_{41}H_{51}GaN_2Te_2$ : C, 54.91; H, 5.73; N, 3.12. Found: C, 55.30; H, 5.81; N, 3.13%.  $^1H$  NMR (300 MHz,  $C_6D_6$ ):  $\delta$  7.54 (m,  $o-H$  Ph, 4 H), 7.18 (m,  $C_6H_3(^1Pr)_2$ , 6 H), 6.96 (m,  $p-H$  Ph, 2 H), 6.78 (m,  $m-H$  Ph, 4 H), 4.76 (s,  $\gamma-CH-$ , 1 H), 3.62 (sept,  $-CH(CH_3)_2$ , 4 H), 1.50 (s,  $ArNCCH_3$ , 6 H), 1.48 (d,  $-CH(CH_3)_2$ , 12 H), 1.08 (d,  $-CH(CH_3)_2$ , 12 H).  $^{13}C$  NMR (75.5 MHz,  $C_6D_6$ ):  $\delta$  170.63 ( $ArNCCH_3$ ), 145.36 ( $Ar$ ), 142.05 ( $Ar$ ), 141.58 ( $Ar$ ), 128.91 ( $Ar$ ), 128.21 ( $Ar$ ), 126.81 ( $Ar$ ), 125.47 ( $Ar$ ), 108.69 ( $Ar$ ), 99.22 ( $\gamma-CH-$ ), 29.36 ( $-CH(CH_3)_2$ ), 27.01 ( $-CH(CH_3)_2$ ), 25.44 ( $-CH(CH_3)_2$ ), 24.67 ( $ArNCCH_3$ ).  $^{125}Te$  NMR (95 MHz,  $C_6D_6$ ):  $\delta$   $-21.94$ . IR (neat):  $\nu$  3051 (w), 2962 (m), 2923 (w), 2863 (w), 1521 (m), 1460 (m), 1366 (m), 1311 (m), 1254 (m), 1169 (w), 1103 (w), 1014 (m), 935 (w), 861 (w), 797 (m), 727 (s), 689 (s), 636 (w), 531 (w), 451 (m)  $cm^{-1}$ .

**Synthesis of **3**.** A mixture of  $i-Pr_2Te$  (0.068 g, 50  $\mu$ L, 0.318 mmol) and LGa (0.155 g, 0.318 mmol) in 2 mL of toluene was stirred at ambient temperature for 24 h. The clear solution was concentrated to 1 mL and stored at 5 °C for 3 days to give a large amount of **2** as pale yellow blocks. Yield: 76% (0.169 g). Anal. Calcd for  $C_{35}H_{55}GaN_2Te$ : C, 59.96; H, 7.91; N, 4.00. Found: C, 60.10; H, 7.98; N, 3.97%.  $^1H$  NMR (300 MHz,  $C_6D_6$ ):  $\delta$  7.14 (m,  $C_6H_3(^1Pr)_2$ , 6 H), 4.67 (s,  $\gamma-CH-$ , 1 H), 4.16 (sept,  $-CH(CH_3)_2$ , 2 H), 3.82 (sept,  $-TeCH(CH_3)_2$ , 1 H), 3.42 (sept,  $-CH(CH_3)_2$ , 2 H), 1.87 (d,  $-CH(CH_3)_2$ , 6 H), 1.61 (d,  $-CH(CH_3)_2$ , 6 H), 1.51 (s,  $ArNCCH_3$ , 6 H), 1.32 (m,  $-CH(CH_3)_2$ , 12 H), 1.08 (d,  $-CH(CH_3)_2$ , 6 H), 1.04 (m,  $-GaCH(CH_3)_2$ , 1 H), 0.67 (d,  $-GaCH(CH_3)_2$ , 6 H).  $^{13}C$  NMR (75.5 MHz,  $C_6D_6$ ):  $\delta$  169.78 ( $ArNCCH_3$ ), 146.22 ( $Ar$ ), 143.88 ( $Ar$ ), 142.73 ( $Ar$ ), 127.74 ( $Ar$ ), 126.09 ( $Ar$ ), 124.32 ( $Ar$ ), 98.25 ( $\gamma-CH-$ ), 32.51 ( $-CH(CH_3)_2$ ), 29.35 ( $-CH(CH_3)_2$ ), 28.48 ( $-CH(CH_3)_2$ ), 25.53 ( $-CH(CH_3)_2$ ), 25.40 ( $-CH(CH_3)_2$ ), 24.82 ( $-CH(CH_3)_2$ ), 24.03 ( $-CH(CH_3)_2$ ), 21.90 ( $ArNCCH_3$ ), 17.67 ( $-TeCH(CH_3)_2$ ), 1.79 ( $-GaCH(CH_3)_2$ ), 1.76 ( $-GaCH(CH_3)_2$ ).  $^{125}Te$  NMR (95 MHz,  $C_6D_6$ ):  $\delta$   $-115.74$ . IR (neat):  $\nu$  2964 (m), 2919 (w), 2849 (w), 1551 (w), 1521 (m), 1438 (m), 1383 (s), 1312 (m), 1258 (m), 1172 (w), 1098 (m), 1017 (s), 935 (w), 862 (w), 796 (s), 757 (m), 526 (m), 440 (w), 402 (w)  $cm^{-1}$ .

### Single crystal X-ray diffraction

Crystallographic data of **1–3**, which were collected on a Bruker D8 Kappa APEX2 diffractometer ( $MoK_\alpha$  radiation,  $\lambda$  = 0.71073 Å) at 130(1) K (**1a**), 100(1) K (**1b**), 100(1) K (**2**) and 100(1) K (**3**), are summarized in Table 1. The solid-state struc-

tures of **1–3** are shown in Fig. 1–3. The structures were solved by Direct Methods (SHELXS-97) and refined anisotropically by full-matrix least-squares on  $F^2$  (SHELXL-97).<sup>54,55</sup> Absorption corrections were performed semi-empirically from equivalent reflections on basis of multi-scans (Bruker AXS APEX2). The toluene molecule of **1b** is disordered via  $2/m$  symmetry. Further solvent molecules that could not be modelled sufficiently were removed by a PLATON/SQUEEZE run.<sup>56</sup> The crystal quality of **2** was rather low consequently the quantitative results of the model should be carefully assessed. The resolution of the data of **3** was high enough to show a mismatch of the calculated position of H2 and the residual electron density. Consequently H2 was refined freely with its displacement parameter constrained to be 1.2 times  $U_{eq}$  of the connected C atom. Other hydrogen atoms were refined using a riding model or rigid methyl groups.
