The  $CH_2Cl_2$  complex  $[Rh(^{rBu}PONOP)(\kappa^1-ClCH_2Cl)][BAr^F_4]$  is reported, that also acts as a useful synthon for other complexes such as  $N_2$ , CO and  $H_2$  adducts; while the analogous PNP complex undergoes C–Cl activation.

Coordinatively and electronically unsaturated transition-metal pincer complexes, [M(pincer)], are key intermediates in alkane dehydrogenation processes,1 as well as other catalytic transformations.<sup>2</sup> They have also played a major role in the elucidation of fundamental bond transformations, such as C-H, C-C and C-X breaking and making.3 Recently, Brookhart and co-workers reported the synthesis of transition-metal methane and ethane sigma complexes, by a low temperature (ca. -110 °C to -150 °C) protonation of the corresponding Rh( $^{tBu}$ PONOP)R precursors using [H(OEt<sub>2</sub>)<sub>2</sub>][BAr<sup>F</sup><sub>4</sub>] in CDF<sub>2</sub>Cl-CH<sub>2</sub>Cl<sub>2</sub> solvent to give [Rh(<sup>tBu</sup>PONOP)(H-R)][BAr<sup>F</sup><sub>4</sub>]  $[^{tBu}PONOP = 2,6-(^{t}Bu_{2}PO)_{2}C_{5}H_{3}N; R = Me, Et; Ar^{F} = 3,5-(CF_{3})_{2}C_{6}H_{3}],$ Scheme 1.4 Such complexes are key, but transient, intermediates in C-H bond activation processes. On warming above -87 °C (R = Me) or -130 °C (R = Et) they lose alkane and generate complexes tentatively characterised in situ on the basis of <sup>31</sup>P NMR spectroscopy as  $[Rh(^{tBu}PONOP)(solv)][BAr^{F}_{4}]$  (solv = CDF<sub>2</sub>Cl or CD<sub>2</sub>Cl<sub>2</sub>). These solvent adducts remain to be definitively characterised. They are particularly interesting given their role in alkane coordination chemistry, and more generally as latent-low coordinate intermediates in catalytic processes.

We now report the full characterisation of the  $\mathrm{CH_2Cl_2}$  adduct accessed via a different, halide abstraction, route including a single crystal X-ray diffraction study and its onward reactivity. We also demonstrate that changing the pincer ligand to the more electron donating  $^{t\mathrm{Bu}}\mathrm{PNP}$  [2,6- $(^t\mathrm{Bu_2PCH_2})_2\mathrm{C_5H_3N}$ ] results in C-Cl bond activation of the solvent molecule.

Scheme 1 Formation of a sigma alkane complex and decomposition to give tentatively characterised solvent complexes (Brookhart and coworkers).  $[BAr^F_a]^-$  anions are not shown.<sup>4</sup>

Addition of Na[BAr $^{F}_{4}$ ] to a CH<sub>2</sub>Cl<sub>2</sub> solution of Rh( $^{tBu}$ PONOP)Cl, 1,  $^{4a}$  results in the formation of orange [Rh( $^{tBu}$ PONOP)-( $\kappa^{1}$ -ClCH<sub>2</sub>Cl)][BAr $^{F}_{4}$ ], 2 (Scheme 2). Filtration and removal of the solvent affords 2 in good isolated yield as a powder. Complex 2 can be recrystallised from CH<sub>2</sub>Cl<sub>2</sub>-pentane under an Ar atmosphere to give crystals suitable for an X-ray diffraction study. Under these conditions, orange 2 crystallises alongside the dinitrogen adduct, [Rh( $^{tBu}$ PONOP)( $\kappa^{1}$ -N<sub>2</sub>)][BAr $^{F}_{4}$ ], 3, in an approximate 1:1 ratio (as measured by  $^{31}$ P NMR spectroscopy, *vide infra*). Single crystals of 2 suitable for an X-ray diffraction study were obtained by mechanical separation from orange/brown 3.‡ Presumably the exogenous N<sub>2</sub> comes from trace (1–2 ppm) levels of N<sub>2</sub> present in the argon, as has been noted previously,  $^{5}$  and is driven by relative solubilities of

Scheme 2 Synthesis of complex 2. [BAr<sup>F</sup><sub>4</sub>]<sup>-</sup> anion is not shown.

(5) Rh1-Cl1, 2.311(2); Rh1-N1, 2.066(6); Rh1-P1, 2.335(2); Rh1-P2, 2.339(2); Rh1-C8, 2.196(15); C8-Cl2, 1.79(2); Rh1-C8-Cl2, 112.5(9). Complex 5 co-crystallises with [Rh(fBuPNP)(H)Cl]- $[BAr^{F_4}]$ , 6, at the same lattice position in a 50:50 ratio.

2 and 3; as in neat CD<sub>2</sub>Cl<sub>2</sub> under the same Ar atmosphere 2 does not go onto to form 3 to the detection limit of <sup>31</sup>P{<sup>1</sup>H} NMR spectroscopy. The solid-state structure (Fig. 1A) shows a pseudo square planar cationic [Rh(\*BuPONOP)]\* centre coordinated in the fourth position by a CH2Cl2 molecule. The Rh-Cl1 distance [2.350(2) Å] is significantly shorter than reported for related [RhCp\*(PMe<sub>3</sub>)(Ph)(κ¹-ClCH<sub>2</sub>Cl)][BAr<sup>F</sup><sub>4</sub>],<sup>6</sup> 2.512(2) Å, and  $[RhCp*(PMe_3)(Me)(\kappa^1-ClCH_2Cl)][BAr^F_4]$ , 2.488(1) Å Cp\* =  $\eta^5$ -C<sub>5</sub>Me<sub>5</sub>). Complex 2 adds to the relatively small number of CH2Cl2 complexes that have been crystallographically characterised, and in particular CH2Cl2 adducts of pincer, or closely related, complexes.8

Although the short Rh-Cl distance might suggest a stronger interaction in 2, in solution (vide infra) rapid exchange between solvent and bound CH2Cl2 occurs. The two C-Cl distances in the bound solvent molecule are similar, 1.710(8) [C22-Cl1] and 1.758(7) [C22-Cl2] Å, although the distal C-Cl bond is the slightly longer of the two. This is in contrast to other reported CH<sub>2</sub>Cl<sub>2</sub> complexes in which the bound C-Cl bond is longer.<sup>8,9</sup> We suggest that the slight lengthening of C22-Cl2 may be due to a number of weak C-H···Cl hydrogen bonds between proximal <sup>t</sup>Bu groups and Cl2.<sup>10</sup>

Complex 2 is stable in the solid-state under an Ar atmosphere, and in solution (CD2Cl2) for at least 1 week. In the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum (CD<sub>2</sub>Cl<sub>2</sub>) a single resonance is observed at  $\delta$  204.5 [I(RhP) 136 Hz]. These data are identical to those previously reported by Brookhart and co-workers for the complex tentatively characterised as  $[Rh(^{tBu}PONOP)(CH_2Cl_2)][BAr^F_{\phantom{a}4}]$ , *i.e.* 2. The <sup>t</sup>Bu groups are observed as a single environment in the <sup>1</sup>H NMR spectrum. The bound CH<sub>2</sub>Cl<sub>2</sub> ligand is not observed, even at -80 °C in the <sup>13</sup>C{<sup>1</sup>H} NMR spectrum, presumably as it is undergoing fast exchange with the solvent. 11 The electrospray ionisation mass spectrum of 2 using N2 as a desorption gas showed only 3 as the molecular ion.

Complex 2 is a useful synthon for the preparation of other pincer complexes (Scheme 3). Addition of H2 to a CD2Cl2 solution of 2 forms the previously reported dihydrogen complex  $[Rh(^{tBu}PONOP)(\eta^2-H_2)][BAr^F_4]^{12} [\delta(^1H) -8.27, lit. -8.26].$ Addition of  $N_2$  forms the new complex  $[Rh(^{tBu}PONOP)(\kappa^1-N_2)]$ -

Scheme 3 Reactivity of complex 2. CH<sub>2</sub>Cl<sub>2</sub> solvent. [BAr<sup>F</sup><sub>4</sub>]<sup>-</sup> anions are not shown.

[BAr<sup>F</sup><sub>4</sub>], 3, for which a solid-state structure is shown in Fig. 1B. This demonstrates an end-on bound, monomeric, N2 adduct [N-N, 1.063(5); Rh-N2, 1.967(3) Å]. The  ${}^{31}P{}^{1}H{}$  NMR spectrum displays a single environment at  $\delta$  211.0 [ I(RhP) 132 Hz], while in the IR spectrum the N-N stretch is observed at 2201.9 cm<sup>-1</sup>. The N-N bond length is very similar (albeit a little shorter) than that in free  $N_2$  [1.09 Å], suggesting only a small degree of activation. Complex 3 can also be compared with previously reported  $[Rh(^{tBu}PNP)(\kappa^1-N_2)][OTf]$  which shows a slightly longer N-N bond, a shorter Rh-N bond and a more red-shifted N-N stretch: 1.116(4), 1.898(3) Å, and 2153 cm<sup>-1</sup> respectively; suggesting greater N2 activation for this more electron rich pincer ligand.13 This greater metal-based basicity in the <sup>tBu</sup>PNP complexes is reflected in the CO stretching frequencies of the corresponding CO-adducts: [Rh(tBuPONOP)(CO)][BArF4], 4 [2020 cm<sup>-1</sup>] and  $[Rh(^{tBu}PNP)(CO)][BAr^{F}_{4}]$  [1982 cm<sup>-1</sup>]. <sup>14</sup> Complex 4 was prepared by adding CO to a CH2Cl2 solution of 2, further demonstrating the utility of complex 2 in synthesis.

The difference in electron-donating power of the <sup>tBu</sup>PONOP versus tBuPNP ligands can also been shown by the attempted synthesis of the CH<sub>2</sub>Cl<sub>2</sub> adduct of the {Rh(<sup>tBu</sup>PNP)}<sup>+</sup> fragment, analogous to complex 2. Rather than simple coordination, this resulted in a number of products as measured by <sup>31</sup>P{<sup>1</sup>H} NMR spectroscopy. Analysis of single crystals suitable for an X-ray

diffraction study, obtained from recrystallisation of the reaction mixture, demonstrated co-crystallisation of two complexes  $[Rh(^{tBu}PNP)(CH_2Cl)Cl][BAr^F_4]$ , 5, and  $[Rh(^{tBu}PNP)-(H)Cl][BAr^F_4]$ , 6, in an approximate 50:50 ratio (Scheme 4); for which the solid-state structure of 5 is shown in Fig. 1C. Because of this co-crystallisation the metrical data associated with 5 should be treated with caution. The  $^1H$  NMR spectrum of these crystals showed a broad hydride signal at  $\delta$  –15.48 (relative integral relative to  $[BAr^F_4]$  of ~0.5 H) which is assigned to 6. Given the number of products formed we are reluctant to speculate on mechanism of formation of 6, but protonation of 5 by trace acid arising from other decomposition pathways could form 6. Addition of  $H_2$  to this mixture of 5 and 6 in  $CD_2Cl_2$  afforded mixture of products, from which  $[Rh(^{tBu}PNP)-(\eta^2-H_2)][BAr^F_4]$  could be identified as the major species present.  $^{16}$ 

#### Conclusions

The  $CH_2Cl_2$  complex  $[Rh(^{tBu}PONOP)(\kappa^1-ClCH_2Cl)][BAr^F_4]$  has been isolated, confirming its formation in the decomposition of the corresponding alkane adduct at low temperature, itself formed from protonation of an alkyl precursor. Synthesis has been achieved by an alternative halide-abstraction route in  $CH_2Cl_2$  solvent, starting from a readily available chloride precursor. This complex, with its weakly bound  $CH_2Cl_2$  ligand, also acts as a useful synthon for other complexes such as  $N_2$ , CO and  $CH_2$  adducts. The corresponding PNP ligand complex undergoes CC activation to form a mixture of products, highlighting the difference in electron donating properties of these two ligands.
