The synthesis and isolation of two potassium, one lithium and two calcium complexes of imidazol-2-ylidene-*N'*-phenylureate ligands [Im^RNCON(H)Ph] (R = *t*Bu (**1a**); Mes (**1b**) and Dipp (**1c**); Mes = mesityl, Dipp = 2,6-diisopropylphenyl) are described. Potassium complexes, $[\{\kappa^2\text{-}(\text{Im}^{\text{Mes}}\text{NCONPh})\text{K}\}_4]$ (**2b**) and $[\{\kappa^3\text{-}(\text{Im}^{\text{Dipp}}\text{NCONPh})\text{K}\}_2\{\text{KN}(\text{SiMe}_3)_2\}_n]$ (**2c**), were prepared in good yields by the reactions of **1b** and **1c**, respectively, with potassium bis(trimethyl)silyl amide at ambient temperature in toluene. Lithium complex $[\{(2,6\text{-}t\text{Bu}_2\text{-}4\text{-Me-C}_6\text{H}_2\text{O})\text{Li}(\text{Im}^{\text{tBu}}\text{NCON}(\text{H})\text{Ph})_2(\text{Im}^{\text{tBu}}\text{NCON}(\text{H})\text{Ph})\}]$ (**3a**) was isolated by a one-pot reaction between **1a** and LiCH₂SiMe₃, followed by the addition of 2,6-*t*Bu₂-4-Me-C₆H₂OH in toluene. Calcium complex $[\{\kappa^2\text{-}(\text{Im}^{\text{tBu}}\text{NCONPh})\text{Ca}(\text{N}(\text{SiMe}_3)_2)\text{-}(\text{KN}(\text{SiMe}_3)_2)\}_n]$ (**4a**) was isolated by the one-pot reaction of **1a** with [KN(SiMe₃)₂] and calcium diiodide in THF at ambient temperature. The solid-state structures of ligand **1a** and complexes **2b**, **2c**, **3a** and **4a** were confirmed by single-crystal X-ray diffraction analysis. It was observed that potassium was coordinated to the oxygen atom of urea group and to the nitrogen atom of the imidazol-2-imine group, in the solid-state structure of **2b**. In complex **4a**, the calcium ion was ligated to the monoanionic imidazol-2-ylidene-*N'*-phenylureate ligand in a bi-dentate (κ^2) fashion through the oxygen and nitrogen atoms of the isocyanate building block leaving the imidazol-2-imine fragment uncoordinated. In the solid state of the potassium complex **2c**, tri-dentate (κ^3) coordination from the imidazol-2-ylidene-*N'*-phenylureate ligand was observed through the oxygen and nitrogen atoms of the isocyanate building block and of the imidazol-2-imine fragment. In contrast, in the dimeric lithium complex **3a**, the neutral imidazol-2-ylidene-*N'*-phenylureate ligand was bound to the lithium centre in a mono-dentate fashion (κ^1) through an oxygen atom of the isocyanate moiety. It is to be noted that in each complex thus observed, the elongated carbon–nitrogen bond distances indicate substantial electron delocalisation from the imidazole ring to the ureate group present in ligand **1**.

Introduction

From an early stage, ligands with amine or imine functionality have played an important role in the field of coordination chemistry.¹ After the remarkable discovery of the first stable and structurally characterised imidazol-2-ylidene by Anthony Joseph Arduengo, III, N-heterocyclic carbenes (NHCs) immediately

became indispensable to developments in many diverse research areas, such as homogeneous catalysis,² materials science³ and medicinal chemistry.⁴

The enhanced electron-donating capacity and high nucleophilicity observed in these carbenes are indicative of the capability of the imidazolium ring to effectively stabilise a positive charge. An analogous principle can be applied to organic imidazol-2-ylidene derivatives containing an *exo*-cyclic atom or an organic moiety X attached at the 2-position of the N-heterocycle such that, for species such as 2-methylene-, 2-imino-, 2-oxo- and 2-thioimidazolines (X = CH₂, NH, O, S), a strong contribution from the ylidic mesomeric form **1B** may be considered (Chart 1).^{5,6}

It was established that, due to the resulting build-up of negative charge at the X atom due to the mesomeric form **1B**, the atom X possesses enhanced basicity and nucleophilicity.⁷ In recent years, Tamm and co-workers exploited this concept

Chart 1 Mesomeric forms of imidazolin-2-iminato ligand.

by providing access to a large variety of novel imidazolin-2-imines (ImNH, X = NH) that can be used for the preparation of imidazolin-2-iminato complexes of transition metals and rare earth elements, and, more recently, of actinide metals, in order to achieve very short M–N bonds. This has led to the probability of a multiple bonding character between M–N bonds.⁸ The M–N bond possesses a multiple bonding character – its reactivity is described as being very similar to a M=N imido bond.⁹ It has been observed that various metal complexes supported by imidazolin-2-iminato ligands display high activity in ethylene (co)polymerisation and in alkyne metathesis.¹⁰

Lavoie *et al.* recently reported the preparation of urea and the thio-urea derivatives imidazol-2-ylidene-*N'*-*p*-tolylureate and imidazol-2-ylidene-*N'*-*p*-tolylthioureate from imidazolin-2-imines and *p*-tolyl isocyanate and isothiocyanate, respectively.¹¹ This family of neutral polydentate ligands incorporates the imidazolin-2-imine fragment in its fold. Lavoie *et al.* also introduced these urea- and thio-urea functionalised ligands into groups 4 and 10 in transition metal chemistry in order to explore their coordination behaviours. It was observed that these bi-dentate urea- and thio-urea functionalised ligands bound more electro positive titanium (Ti⁴⁺) ions through the nitrogen and oxygen atoms of the isocyanate building block, while leaving the imidazol-2-imine fragment uncoordinated. However, they found the lesser electropositive metal ions (Ni²⁺ and Pd²⁺) to be ligated through both the nitrogen atoms of the ligand. Nevertheless, their work was restricted to transition metal chemistry, and the structural aspects of alkali metal and alkaline earth metal complexes with these ligands have not been reported to date.

We earlier reported on phosphine-functionalised imidazolin-2-imines, imidazolin-2-ylidene-1,1-diphenylphosphine-amine and their chalcogenide derivatives (O, S, Se and Te).¹² In our ongoing efforts to prepare functionalised imidazolin-2-imines, and with an interest to observe and record their coordination behaviour towards the main group organometallics, we prepared various alkali metal and alkaline earth metal complexes with imidazolin-2-imine urea derivatives.

It is in this context that herein we present the synthetic and structural details of two potassium complexes [$\{\kappa^2\text{-(Im}^{\text{Mes}}\text{NCONPh)K}\}_4$] (**2b**) and [$\{\kappa^3\text{-(Im}^{\text{Dipp}}\text{NCONPh)K}\}_2\{\text{KN}(\text{SiMe}_3)_2\}_2$]_n (**2c**), one lithium complex (**3a**) and one calcium complex [$\{\kappa^2\text{-(Im}^{\text{tBu}}\text{NCONPh)-Ca}\{\text{N}(\text{SiMe}_3)_2\}\{\text{KN}(\text{SiMe}_3)_2\}\}_n$] (**4a**) of imidazol-2-ylidene-*N'*-phenylureate ligand [Im^RNCON(H)Ph] [(R = *t*Bu (**1a**);

Mes (**1b**) and Dipp (**1c**); Mes = mesityl, Dipp = 2,6-diisopropylphenyl]. We also report the molecular structures of an imidazol-2-ylidene-*N'*-phenylthioureate ligand (**1d**) and a siloxane incorporated calcium complex [$\{\kappa^3\text{-(Im}^{\text{tBu}}\text{NCONPh)}\}_2\text{-Ca}(\text{OSiMe}_2\text{OSiMe}_2\text{O})_2\{\kappa^3\text{-(Im}^{\text{tBu}}\text{NCONPh)CaK}\}_2\{\text{KN}(\text{SiMe}_3)_2\}_2\text{-[Ca}(\text{N}(\text{SiMe}_3)_2\text{)]}_n$] (**5a**).

Results and discussion

Ligand synthesis

The imidazol-2-ylidene-*N'*-phenylureate and -thioureate ligands were prepared by an analogous method to that reported by Lavoie *et al.*¹¹ Imidazolin-2-imines (Im^RNH) with three different substituents over nitrogen atoms were charged with a slight excess of phenyl isocyanate (5% excess) at ambient temperature to give the corresponding imidazol-2-ylidene-*N'*-phenylureate [Im^RNCON(H)Ph] (R = *t*Bu (**1a**); Mes (**1b**) and Dipp (**1c**)) (Scheme 1). The analogous thioureate ligand [Im^{tBu}NCSN(H)Ph] (**1d**) was isolated by the reaction of [Im^{tBu}NH] with phenyl isothiocyanate in toluene (Scheme 1). All the ligands were characterised using standard analytical and spectroscopic techniques. The solid-state structures of **1a** and **1d** were established by single-crystal X-ray diffraction analysis.

The ¹H NMR spectra measured in C₆D₆ for the compounds **1a–c** and CDCl₃ (**1d**) are similar and show a characteristic singlet resonance [δ 6.18 (**1a**), 5.80 (**1b**), 6.10 (**1c**) and 6.22 (**1d**) ppm] for imidazolium backbone olefinic protons. These can be observed as a downfield shift from that of the respective imidazol-2-imines [δ 5.96 (*t*Bu); 5.71 (Mes); 5.87 (Dipp) ppm]. The resonances for 18 protons from the six methyl groups in **1a** appeared as singlets at δ 1.43 ppm, whereas two singlets at δ 2.26 and 2.05 ppm could be assigned to the *o*- and *p*-methyl protons, respectively, in the mesityl groups. The distinct septet signal at δ 3.21 ppm, and the two doublet resonances with a coupling constant 6.8 Hz each, appeared at δ 1.45 and 1.16 ppm, respectively, due to the –CH hydrogen and isopropyl methyl hydrogen atoms of the ligand **1c**. The C=O stretching frequencies [ν 1627 (**1a**), 1647 (**1b**), 1650 (**1c**) cm⁻¹] were considerably lower than that of the starting isocyanate (2170 cm⁻¹), indicating a marked reduction in C–O strength upon formation of the urea. As the observed stretching frequencies were also slightly lower than those commonly observed in organic amides¹³ – a manifestation of the electron

Scheme 1 Synthesis of imidazol-2-ylidene-*N'*-phenylureate/thioureate ligands.

Fig. 1 Solid-state structure of ligand **1a**. Selected bond lengths [Å] and bond angles [°]: N1–C12 1.339(3), N4–C12 1.389(3), C12–O1 1.236(3), N1–C1 1.346(3), C1–N2 1.362(3), C1–N3 1.358(3), C2–C3 1.324(4), N1–C12–N4 111.1(2), N1–C12–O1 127.1(2), N4–C12–O1 121.8(2).

delocalisation from the imidazole ring to the acyl group – a further decrease of the C–O bond order can be realised. The resonance for the *tert*-butyl methyl protons in compound **1d** could be detected as a sharp singlet at δ 1.65 ppm. The strong absorption band at 1400–1600 cm^{-1} in the FT-IR spectrum of **1d** indicated the presence of a C=S group. However, the exact band was difficult to identify due to the mixing of the other vibration modes.¹⁴

Single crystals of **1a** and **1d** were obtained from the concentrated toluene solution of the respective compounds at ambient temperature. Compound **1a** crystallised in the monoclinic space group $P2_1/c$ with four molecules in the unit cell. In contrast, the thiourea derivative **1d** crystallised in the trigonal space group $R\bar{3}$ with 18 molecules in the unit cell. The details of the structural parameters are given in Table TS1 in the ESI.† The solid-state structure of complex **1a** is shown in Fig. 1, whereas Fig. S1 in the ESI† represents the solid-state structure of **1d**. The C1–N1 bond distance of 1.346(3) Å in **1a** is elongated, compared to $\text{Im}^{\text{tBu}}\text{NH}$ [1.295(2) Å],¹⁵ presumably due to enhanced electron donation to the imino nitrogen atom from the imidazolium ring. A slight elongation of the carbonyl C12–O1 bond [1.236(3) Å] was observed due to the delocalisation of electrons from imino nitrogen to the oxygen atom of the isocyanate building block. The slightly shorter N1–C12 bond [1.339(3) Å], compared to the N4–C12 bond [1.389(3) Å], is also supportive of the above delocalisation over the N1–C12–O1 unit on ligand **1a**. Short hydrogen bonding between the electronegative oxygen atom and hydrogen atoms from adjacent methyl groups, O1...H5a (2.706 Å) and O1...H9c (2.541 Å), is also observed (Fig. 1).

Potassium complexes

In the recent past, we reported the syntheses and structural studies of highly reactive alkali metal complexes in order to apply them well-defined precursors for various salt metathesis

Scheme 2 Synthesis of the heterocubane potassium complex **2b**.

reactions.¹⁶ To gain an additional insight into the structure–reactivity relationships of alkali metal complexes of imidazol-2-ylidene-*N'*-phenylureate ligands, we studied this chemistry further. The mesityl derivative of the ligand (**1b**) was reacted with potassium bis(trimethylsilyl)amide in a 1 : 1 molar ratio and at ambient temperature in toluene to afford the tetranuclear structure **2b** in a good yield (Scheme 2). The ligand **1d** was reacted in a similar fashion with alkali and alkaline earth metal precursors; however, we could not isolate any of the corresponding alkali metal or alkaline earth metal complexes, probably due to the soft nature of the sulfur atom which did not have a preference for the hard metal ions. The polymeric potassium complex **2c** was isolated in a good yield by the reaction of **1c** and potassium bis(trimethylsilyl)amide in a 1 : 2 molar ratio in toluene at room temperature (Scheme 3). The air- and moisture-sensitive compounds **2b** and **2c** were characterised using ^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectroscopy, and the solid-state structures of complexes **2b** and **2c** were established by single-crystal X-ray diffraction analysis.

The ^1H NMR spectra of complexes **2b** and **2c**, measured in C_6D_6 , revealed one set of signals in each case. The two olefinic protons of the imidazole backbone resonated at δ 5.80 (**2b**) and 5.95 ppm (**2c**), respectively. These in a similar range to those of the starting urea ligands (5.80 ppm for **1b** and 6.10 ppm for **1c**). The methyl protons of the mesityl groups in **2b** were observed to resonate at δ 2.26 and 2.06 ppm as two sharp singlets. Furthermore, in complex **2c**, a broad signal at δ 3.16 ppm and two doublet resonances with a coupling constant of 8.4 Hz each appeared at δ 1.29 and 1.19 ppm, respectively, due to the –CH hydrogen and isopropyl methyl hydrogen atoms of the imidazolin-2-imine fragment of ligand **1c**. A sharp singlet at δ 0.09 ppm was also observed for the trimethylsilyl group present in complex **2c**. In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectra of **2b** and **2c**, the chemical shift of the central imidazole carbon was observed at 149.6 ppm for **2b** (*versus* 146.7 ppm for **1b**) and at 147.5 ppm for **2c** (*versus* 150.5 ppm

Scheme 3 Synthesis of the polymeric potassium complex **2c**.

for **1c**), while the carbonyl carbon nucleus resonated at δ 158.2 ppm for **2b** (versus 154.2 ppm **1b**) and at 165.2 ppm for **2c** (versus 157.2 ppm for **1c**). The decrease in the C=O stretching frequency ($\nu_{\text{CO}} = 1623 \text{ cm}^{-1}$ for **2b** and 1620 cm^{-1} for **2c**) compared to that of the urea ligands **1b** ($\nu_{\text{CO}} = 1647 \text{ cm}^{-1}$) and **1c** ($\nu_{\text{CO}} = 1647 \text{ cm}^{-1}$) also supported coordination through the oxygen atom.

X-ray quality crystals of complex **2b** were grown at $-35 \text{ }^\circ\text{C}$ by the slow liquid diffusion of THF into a concentrated toluene solution, while single crystals of **2c** were obtained at $-35 \text{ }^\circ\text{C}$ from a concentrated solution of toluene. Complex **2b** crystallised in the tetragonal space group $P4_21c$, with two molecules of complex **2b** and two THF solvent molecules in the unit cell. In contrast, complex **2c** crystallised in the monoclinic space group $P2_1/c$, with four molecules of **2c** in the unit cell.

Complex **2b** is tetra-nuclear monomeric, whereas complex **2c** is polymeric in nature. Details of the structural parameters are given in Table TS1 in the ESI.† The solid-state structure of complex **2b** is shown in Fig. 2. This solid-state structure of the tetra-nuclear potassium complex **2b** confirmed the κ^2 -coordination mode of each ligand fragment forming four times four-membered metallacycles. Each potassium is ligated with the imidazolium-2-iminato nitrogen and the oxygen atom of the isocyanate building block. Four potassium and four oxygen atoms formed a heterocubane structure, with an average K–O distance of 2.659–2.709 Å and a K–O–K angle between $80.37(8)$ and $89.15(8)^\circ$, thus confirming the distorted nature of the heterocubane motif, which can be best described as a K_4 tetra-

Fig. 3 The heterocubane core in **2b** formed by potassium and oxygen atoms.

hedron consisting of four oxygen atoms capping the four triangular faces (Fig. 3). Significant electron donation from the imidazolium ring to the ureate group is evident from the unusual elongation of the N1–C27 (1.411(5) Å) and N1–C1 [1.285(5) Å] bonds. In addition, both the bond lengths C27–O1 [1.279(4) Å] and C27–N4 [1.309(5) Å] are between those of carbon–oxygen and carbon–nitrogen single bonds and double bonds, respectively, thus indicating extensive electron delocalisation over N1–C27–O1. A similar observation was reported in $[\text{CpTiCl}_2(\text{Im}^{\text{Mes}}\text{NCONTol})](\text{Tol} = p\text{-tolyl})$ by Lavoie *et al.*¹¹ They, however, reported a bi-dentate mode of coordination of the ureate ligand through the oxygen and nitrogen atoms of the isocyanate building block, while leaving the imidazolium-2-imine fragment uncoordinated. To the best of our knowledge, complex **2b** is the first reported ureate–potassium complex where the mono-anionic ligand is coordinated through the oxygen atom of the ureate group and the nitrogen atom from the imidazolium-2-imine fragment. An even similar pattern of bonding was discussed by Snaith *et al.*, although it must be noted that such a heterocubane structural motif, derived using an ureate ligand in alkali metal chemistry, has not been reported so far.¹⁷

The effect of a substituent over the imidazol ring is very significant. The solid-state structure of complex **2c** was found to be polymeric in nature, due to the use of two equivalents of potassium precursor in its preparation compared to one equivalent used for the synthesis of **2b**. The asymmetric unit of complex **2c** is shown in Fig. 4. The molecular structure of **2c** confirms the κ^3 coordination of the ureate ligand towards potassium. It further reveals that two molecules $[\text{KN}(\text{SiMe}_3)_2]$ are also present in the asymmetric unit in order to stabilise the complex **2c**. The nitrogen atoms from the imidazolium-2-imine and the ureate fragments bond with the potassium ion K1, whereas the third donor atom oxygen is also ligated to another adjacent potassium ion that is attached to the bis(trimethyl)silyl amide group. Two four-membered metallacycles, N1–K1–N4–C28 and N7–K4–N10–C71, are formed by the chelation of two nitrogen atoms of each ureate ligand with the potassium ion, while two six-membered metallacycles, N4–C28–O1–K3–C30–C29 and N10–C71–O2–K2–C37–C72, are observed by the ligation of an oxygen atom and a phenyl carbon of each ureate

Fig. 2 Solid-state structure of complex **2b**. The hydrogen atoms are omitted for clarity. The secondary interactions of the potassium atoms and carbon atoms are shown. Fig. 4 Solid-state structure of complex 2c. The hydrogen atoms are omitted for clarity. The secondary interactions of the potassium atoms and methyl carbon atoms are shown. Selected bond lengths [Å] and bond angles [°]: K1–N1 2.734(4), K1–N4 2.726(4), K1–N5 2.769(4), N1–C28 1.417(5), N4–C28 1.327(6), N4–C29 1.401(5), C28–O1 1.248(5), N1–C1 1.290(5), K2–O2 2.507(3), K2–N5 2.801(4), K2–C34 3.358(7), K3–N6 2.841(4), K3–O1 2.528(3), K3–C30 3.293(6), N5–Si1 1.670(4), N5–Si2 1.666(4), N1–C28–N4 111.2(4), N1–C28–O1 121.4(4), N4–C28–O1 127.2(4), C1–N1–C28 124.8(4), C28–N4–C29 117.9(4), N1–K1–N4 49.02(10), K1–N5–K2 40.61(8), O1–K3–N6 170.44(13), N5–K2–O2 160.99(14), Si1–N5–Si2 133.2(2).

ligand with the potassium ion. The phenyl ring of the isocyanate building block plays a key role in holding the two [(Im^{DIPP}NCONPh)K] units through the bridging of two phenyl-carbon atoms. Thus, an additional two six-membered metallacycles, K1–N4–C29–C34–K2–N5 and K3–N6–K4–N10–C72–C73, are observed as a result of the coordination of the phenyl carbon and nitrogen from the bis(trimethyl)silyl amido fragment. Further units of the molecule grow from the ends of the potassium ions K3 and K4 to lead to complex 2c as a polymer. The bond distances in complex 2c (C1–N1 1.289 Å, C44–N7 1.283(6) Å, N1–C28 1.418(5) Å, N7–C71 1.418(5) Å, N4–C28 1.3276 Å, C71–N10 1.324 (6) Å, C28–O1 1.248(5) Å, C71–O2 1.255(6) Å) are in a range similar to those in complex 2b and indicate a significant electron delocalisation over N1–C28–N4 and N7–C71–N10. To the best of our knowledge, complex 2c is the first example where the monoanionic ureate ligand acts as the κ^3 coordination mode using its three donor atoms. A similar polymeric potassium complex $\{[(K(\mu_4\text{-}o\text{MP}))(\text{THF})][K(\mu_3\text{-}o\text{MP})]_5\}_\infty$ (*o*MP = *o*-methyl phenol) was reported by Boyle and his co-workers.¹⁸ Due to the fluxional nature of the complex 2c, only one set of NMR signals was observed.

Lithium complex

As the ureate ligand has multiple donor atoms, as observed (κ^2 and κ^3) from the above potassium complexes 2b and 2c, multi-dentate coordination was expected from two nitrogen and oxygen atoms. We were interested in exploring the coordination behaviour of monoanionic ureate ligands towards

Scheme 4 Synthesis of the lithium complex 3a.

lithium, a smaller alkali metal. As several attempts to crystallise the lithium complex did not succeed, we reacted the lithium complex prepared from 1a and $\text{LiCH}_2\text{SiMe}_3$ in a 1 : 1 molar ratio in toluene with one equivalent of 2,6-di-*tert*-butyl-4-methyl phenol to afford a lithium derivative, complex 3a (Scheme 4). Complex 3a was characterised using ^1H , $^{13}\text{C}\{^1\text{H}\}$ NMR and combustion analysis, while its solid-state structure was established using single-crystal X-ray crystallography.

In the ^1H NMR spectra of complex 3a measured in C_6D_6 , the characteristic singlet at δ 6.28 ppm could be assigned to the olefinic protons of the imidazol backbone, which was in the same region (6.22 ppm) as that of ligand 1a. The *tert*-butyl methyl protons of the imidazol scaffold resonated at 1.46 ppm, whereas the *t*Bu protons from the phenoxy ring were displayed as sharp singlets at 1.30 ppm. Additional singlet resonance at 2.10 ppm was obtained for the methyl protons located at position 4 of the phenoxy moiety. In the ^{13}C spectra, resonances at 165.5 ppm for *ipso* carbon, 157.0 ppm for carbonyl carbon and 149.9 ppm for NCN group were observed for complex 3a.

Crystals of 3a were grown from a concentrated solution of toluene at -35°C . Complex 3a crystallised in the asymmetric unit in the monoclinic space group $P2_1/c$ along with a molecule of 1a. Details of the structural parameters are given in Table TS1 in the ESI.† The solid-state structure of the lithium fragment of complex 3a is shown in Fig. 5. The molecular structure clearly indicates that the neutral urea ligand 1a coordinated to the lithium ion in a κ^1 mode through the oxygen atom of the isocyanate building block of the ligand. A four-membered Li_2O_2 diamond core was formed by the bridging coordination of two oxygen atoms from two phenoxy ligands. The terminal Li1–O1 bond distance [1.835(9) Å] where the oxygen atom is neutral is slightly shorter than the bridging Li–O2 bond (1.863(9) Å) where the oxygen atom is anionic. Dimeric lithium phenoxy complexes $[(2,6\text{-}t\text{Bu}_2\text{-}4\text{-Me-C}_6\text{H}_2\text{O})\text{Li}(\text{THF})]_2$ and $(2,6\text{-}t\text{Bu}_2\text{-C}_6\text{H}_2\text{O})\text{-Li}(\text{DMSO})_2$, where one solvent (THF or DMSO) molecule is attached with each lithium centre to stabilise the respective complex, have been reported in the literature.¹⁹ Thus, the delocalisation of electrons over the N3–C12–O1 centres was observed in complex 3a. Furthermore, elongation of the C1–N3 bond [1.360(6) Å versus 1.346(3) Å for 1a] and the O1–C12 bond [1.270(6) Å versus 1.236(3) Å for 1a] also supports the above fact. It is assumed that the more nucleophilic lithium complex $[\text{Im}^{t\text{Bu}}\text{NCONPhLi}]$ generated from 1a and $\text{LiCH}_2\text{SiMe}_3$ undergoes a protonolysis reaction with 2,6-di-*tert*-butyl-4-methyl phenol to form the neutral urea ligand and the lithium bis-phenoxo complex 3a. Thus, the

Fig. 5 Solid-state structure of complex **3a**. The hydrogen atoms are omitted for clarity except for those which have bonding interactions with oxygen atoms. Selected bond lengths [Å] and bond angles [°]: Li1–O1 1.835(9), Li1–O2 1.863(9), Li1–O2' 1.911(8), O2–Li1' 1.911(8), O1–C12 1.270(6), N3–C12 1.310(6), C12–N4 1.394(6), C1–N1 1.363(6), Li1–O2–Li1' 49.0(3), O2–Li1–O2' 95.9(4), O1–Li1–O2 140.9(5), O1–C12–N3 127.3(5), O1–C12–N4 115.8(5), N3–C12–N4 116.9(4).

neutral ligand **1a** was trapped by and coordinated to the lithium ion, while another molecule of **1a** remained uncoordinated in the asymmetric unit. Several hydrogen bonding interactions with the adjacent methyl protons from ^tBu groups with more electronegative oxygen atoms, important for the crystallisation of the compound (Fig. 5), were also observed in complex **3a**.

Calcium complex

Alkaline earth metal compounds have been recently employed in various catalytic applications in order to achieve the ring-opening polymerisation of various cyclic esters,²⁰ the polymerisation of styrene and dienes,²¹ and hydroamination and hydrophosphination reactions of alkenes and alkynes.²² Determining the structure and reactivity of alkaline earth metal species is an important step towards the design and development of efficient catalysts. However, a full realisation of the catalytic potential of these elements still requires substantial advances to be made in order to understand their basic coordination and organometallic chemistry. We recently studied various group 2 metal complexes with amido-phosphine and related ligands in order to explore their structure, coordination behaviour and catalytic efficiency.²³ In our ongoing study of alkaline earth metal chemistry, we aim to introduce the mono-anionic ureate ligand **1** into group 2 metal chemistry.

The calcium potassium mixed metal complex **4a** was isolated as a major product from a one-pot reaction with **1a** and potassium precursor [KN(SiMe₃)₂] in a 1 : 3 molar ratio in THF, followed by the addition of one equivalent calcium diiodide at ambient temperature (Scheme 5). However, initial attempts to

Scheme 5 Synthesis of the calcium complex **4a**.

isolate the potassium free calcium iodo complex (**1a**)CaI(THF)_{*n*} using the starting reagents in a 1 : 1 : 1 molar ratio did not meet success. The mixed Ca–K metal complex **4a** was characterised using spectroscopic/analytic techniques and the molecular structure of **4a** in its solid-state structure was established using single-crystal X-ray crystallography.

Complex **4a** crystallised in the monoclinic space group *P*2₁/*c*, with four molecules in the unit cell. From the solid-state structure, it was evident that complex **4a** was polymeric in nature. Details of the structural parameters are given in Table TS1 in the ESI;† the asymmetric unit of complex **4a** is shown in Fig. 6, and the polymeric unit is given in Fig. 7. It is clearly seen in the asymmetric unit that two metal ions of calcium and potassium are, respectively, connected *via* μ₂ bridging of the oxygen atom of the ureate ligand and the nitrogen atom from the bis(trimethylsilyl)amido group. This results in the four-fold coordinated central metal calcium ion adopting a distorted tetrahedral geometry due to the κ² coordination of nitrogen and oxygen atoms from the isocyanate building block of ligand **1a** while leaving the imidazolin-2-imine fragment uncoordinated. Two amido ligands bound the calcium ion to

Fig. 6 Solid-state structure of the asymmetric unit of complex **4a**. The hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and bond angles [°]: Ca1–O1 2.3558(17), Ca1–N4 2.367(2), Ca1–N6 2.317(2), Ca1–N5 2.348(2), K1–O1 2.6199(18), K1–N5 2.989(2), O1–C12 1.308(3), N4–C12 1.357(3), C12–N1 1.342(3), N1–C1 1.338(3), N4–C13 1.389(3), O1–Ca1–N4 56.51(6), N4–Ca1–N6 104.47(8), N5–Ca1–N6 123.39(8), O1–K1–N5 73.68(5), K1–N5–Ca1 91.05(6), O1–C12–N4 114.0(2).

Fig. 7 Polymeric network of complex **4a** in the solid state.

give two additional bonds. Thus, a four-membered metallacycle C1–O2–Ca1–N6 was formed to demonstrate the κ^2 coordination of ligand **1a** towards the calcium ion. The slight elongation of the C12–O1 bond [1.308(3) *versus* 1.236(3) Å for **1a**] and the slight shortening of the C12–N4 bond [1.357(3) *versus* 1.389(3) Å] indicate an electron delocalisation over the O1–C12–N4 skeleton. The unperturbed bond distances of N1–C1 [1.338(3) *versus* 1.346(3) Å] and N1–C12 [1.342(3) *versus* 1.339(3) Å] are supportive of the non-interacting nature of the imidazolin-2-imine fragment towards ligation with both metal ions. In addition, a four-membered metallacycle O1–K1–N5–Ca1 was also formed. The bond distances Ca1–N4 [2.367(2) Å] and Ca1–O1 [2.355(2) Å] were similar to those [2.4356(2) and 2.2805(1) Å respectively] in the monomeric calcium ureate complex [(NacNac)Ca(η^2 -AdN=C(NPh₂)O)(Ad = adamantyl)] reported by Hill and co-workers.²⁴ Similar mixed metal complexes with potassium–calcium, potassium–zinc, lithium–calcium and lithium–magnesium are reported in literature.²⁵ The potassium ion K1 led the formation of the polymeric network by growing repetitive asymmetric units *via* η^3 interactions with the phenyl ring of the adjacent ureate ligand fragment from another unit (Fig. 7). Such a polymeric network structure was realised due to the existence of multiple donor atoms in the ligand. In the NMR spectra of **4a**, the presence of only one set of signals confirmed the fluxional nature of the complex.

The synthesis of complex **4a** was performed as a one-pot reaction, followed by a crystallisation process. An undesired minor product **5a** was also isolated from the re-crystallisation of the second crop solution after complex **4a** had been separated. Complex **5a** was characterised using NMR spectroscopy, and the solid-state structure of **5a** was established by single-crystal X-ray diffraction analysis.

Complex **5a** showed one set of signals in the ¹H NMR spectra measured in C₆D₆. The resonances for the olefinic protons were obtained at δ 6.12 ppm as a singlet, whereas the sharp singlet at δ 1.42 ppm could be assigned to the *tert*-butyl group in the imidazol fragment. In addition, a sharp singlet

for the trimethylsilyl groups was also observed at δ 0.43 ppm, thus confirming the presence of SiMe₃ groups in the complex. The ¹³C{¹H} NMR spectra was also within the expected range and very similar to that of complex **4a**.

Complex **5a** crystallised in the triclinic space group *P* $\bar{1}$, with one molecule in the unit cell. Details of the structural parameters are given in Table TS1 in the ESI,[†] and the asymmetric unit of complex **5a** in its solid-state structure is shown in Fig. 8. The molecular structure is evidence of the incorporation of two fragments of dianionic disiloxane units [(Me₂SiO)₂O]²⁻, which bound three calcium ions in a bridging fashion. Three different chemical environments were observed for four calcium ions present in the molecule. The central calcium ion Ca1 was hexa-coordinated through the four oxygen atoms from two siloxane [(Me₂SiO)₂O]²⁻ units and two oxygen atoms from two ureate ligands, resulting in the adoption of a distorted octahedral geometry around it. Each of the remaining two calcium ions had similar coordination spheres formed by the chelation of two μ_3 oxygen atoms O1 and O2 of two siloxane [(Me₂SiO)₂O]²⁻ units, and two nitrogen and two oxygen atoms of two monoanionic ureate ligands, resulting in the adoption of a distorted tetrahedral geometry around the calcium ion. Interestingly, for two ureate ligands, the nitrogen atoms from the isocyanate building block and the imidazolin-2-imine fragment alternatively bound either a calcium ion (Ca2) or a potassium ion (K2), thus making the ureate ligand a tridentate; the coordination mode can be best described as κ^3 towards a metal ion. Apart from these calcium ions, the fourth calcium ion Ca3 exists as a [Ca{N(SiMe₃)₂}] fragment in the molecule. Two kinds of potassium ions were also observed. The potassium ion K1 bound with two μ_3 oxygen atoms (O1 and O2) from the two siloxane [(Me₂SiO)₂O]²⁻ units and with two oxygen atoms (O3 and O4) from two isocyanate building blocks of the ureate ligand. Furthermore, a η^6 attachment with an adjacent phenyl ring with a distance of (2.992–3.317 Å), which is quite common in potassium organometallic complexes, was also obtained.²⁶ The second potassium atom K2, having one [N(SiMe₃)₂]⁻ group attached, was coordinated by one

Fig. 8 Solid-state structure of asymmetric unit of complex **5a**. The hydrogen atoms are omitted for clarity. Selected bond lengths [Å] and bond angles [°]: Ca1–O1 2.329(3), Ca1–O1' 2.329(3), Ca1–O2 2.339(3), Ca1–O3 2.370(3), Ca2–O1 2.332(3), Ca2–O2 2.290(3), Ca2–O4 2.389(3), Ca2–N7 2.390(4), Ca2–N6 2.372(4), Ca2–C11 2.965(5), Ca2–C12 2.804(5), K1–O3' 3.314(4), K1–O1 2.768(3), K1–O2 2.694(4), K2–N8 2.734(4), K2–N3 2.907(4), O3–C11 1.301(6), N6–C11 1.390(6), N10–C11 1.316(6), Si1–O5 1.634(4), Si1–O1 1.606(3), O1–Ca1–O2 79.75(11), O1–Ca1–O2' 100.25(11), O1–Ca1–O1' 180.000(1), O1–Ca1–O3 83.22(12), O1–Ca2–O3 77.57(11), O1–Si1–O5 112.20(19), O5'–Si2–O2 110.86(19).

imidazolin-2-imine nitrogen N3 along with a η^6 arene interaction with the adjacent phenyl ring with a distance of (3.165–3.452 Å). Even the imidazol-2-iminato exocyclic C–N bond distances [N3–C24 1.342(6) Å and N6–C13 1.349(6) Å *versus* 1.346(3) Å for **1a**] remained unchanged. The bond elongation of the ureate fragments [N3–C12 1.362(6) and N6–C11 1.391(6) Å *versus* 1.339(3) Å for **1a**; C12–O4 1.299(6) and C11–O3 1.301(6) Å *versus* 1.236(3) Å for **1a**] led to the conclusion that electron delocalisation occurs mainly on the N3–C12–O4 and N6–C11–O3 skeletons. The shortening of bonds C12–N7 1.341(6) and C11–N10 1.316(6) [*versus* 1.389(3) Å for **1a**] indicated a localised carbon–nitrogen double bond rather than any involvement of electron delocalisation with the C=O group. Thus, it can be assumed that compound **4a** partly underwent decomposition with silicon grease under the reaction conditions so as to afford complex **5a**. However, in a separate reaction, using a silicon-free grease, complex **4a** was prepared without contamination from complex **5a**. In complex **5a**, the calcium ion Ca3 led to the repetition of the asymmetric unit, resulting in the growth of the polymeric chain.

Experimental

General consideration

All manipulations of air-sensitive materials were performed by rigorously excluding oxygen and moisture in flame-dried Schlenk-type glassware, either on a dual manifold Schlenk line interfaced to a high vacuum (10^{-4} torr) line, or in an argon-filled M-BRAUN glovebox. Toluene was distilled under nitrogen from LiAlH_4 and stored in the glove box. ^1H NMR (400 MHz) and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra were recorded on a BRUKER AVANCE III-400 spectrometer. BRUKER ALPHA FT-IR was used for the FT-IR measurements. Elemental analyses were performed on a BRUKER EURO EA at the Indian Institute of Technology Hyderabad (IITH). Imidazolin-2-imines [(Im^RNH)]; (R = *t*Bu,

Mes, Dipp)] and trimethylsilylmethyl lithium [$\text{LiCH}_2\text{SiMe}_3$] were prepared according to procedures specified in literature.¹⁵ Phenyl isocyanate, phenyl isothiocyanate, 2,6-di-*tert*-butyl-4-methyl phenol, $[\text{K}\{\text{N}(\text{SiMe}_3)_2\}]$ and CaI_2 were purchased from Alfa Aesar and used in their original forms. The NMR solvents CDCl_3 and C_6D_6 were purchased from Sigma Aldrich and dried under Na/K alloy prior to use (for C_6D_6).

Preparation of [Im^RNCON(H)Ph] (R = *t*Bu) (**1a**); Mes (**1b**) and Dipp (**1c**)

To a toluene solution (10 mL) of imidazole-2-imine (Im^RNH) (1.56 mmol), 5% molar excess of phenyl-isocyanate (192 mg, 1.612 mmol) was added, and the reaction mixture was stirred for two hours. The solvent was evaporated *in vacuo* leaving behind a solid residue. This colourless solid was washed with *n*-pentane (5 mL) to afford a spectroscopically pure off-white solid. The title compounds were crystallised from concentrated toluene solution at 15 °C.

1a: Yield 420 mg, 86%. ^1H NMR (400 MHz, C_6D_6): δ 7.9 (br, 1H, HN), 7.81 (d, $^3J_{\text{H-H}} = 7.75$ Hz, 2H, Ph), 7.18 (m, 2H, Ph), 6.83 (t, $^3J_{\text{H-H}} = 7.32$ Hz, 1H, Ph), 6.18 (s, 2H, HC=CH), 1.43 (s, 18 H, C(CH₃)₃) ppm. $^{13}\text{C}\{^1\text{H}\}$ NMR (100 MHz, C_6D_6): δ 158.8 (C=O), 150.4 (NCN), 143.4 (Ar), 128.9 (Ar), 120.2 (Ar), 117.8 (Ar), 112.0 (HC=CH), 58.4 (NC(CH₃)₃), 29.1 (C(CH₃)₃) ppm. C 63.19, H 7.82, N 9.21; found C 62.72 H 7.41, N 9.01.

Preparation of [Li(Im^{tBu}NCON(H)-Ph)]₂{Im^{tBu}NCON(H)Ph} (3a)

To a stirred solution of toluene (5 mL) and compound **1a** (200 mg, 0.636 mmol), a toluene (3 mL) solution of trimethylsilyl methyl lithium (60 mg, 0.636 mmol) was added dropwise at ambient temperature. The resulting reaction mixture was stirred for another 12 hours. 2,6-di-*tert*-butyl-4-methyl phenol (140 mg, 0.636 mmol) was added to this solution, and the reaction mixture was stirred for a further 2 hours. The solvent was evaporated and the solution mixture was reduced to 1/3 of the original volume. It was thereafter placed for crystallisation at -35 °C. Colourless crystals were obtained two days later.

Yield 335 mg, 62%. ^1H NMR (400 MHz, C_6D_6): δ 7.57 (d, $^3J_{\text{H-H}} = 8.0$ Hz, 2H, Ar), 7.22 (t, $^3J_{\text{H-H}} = 8.0$ Hz, 2H, Ar), 7.02 (s, 2H, Ar), 6.85 (t, $^3J_{\text{H-H}} = 8.0$ Hz, 1H, Ar), 6.28 (s, 2H, HC=CH), 2.10 (6H, CH₃), 1.46 (s, 18 H, C(CH₃)₃), 1.30 (18H, C(CH₃)₃) ppm. $^{13}\text{C}\{^1\text{H}\}$ NMR (100 MHz, C_6D_6): δ 165.5 (*ipso*-Ar), 157.0 (C=O), 149.9 (NCN), 141.1 (Ar), 133.1 (Ar), 129.3 (Ar), 128.5 (Ar), 128.3 (Ar), 125.8 (Ar), 120.4 (Ar), 119.3 (Ar), 112.1 (HC=CH), 58.6 (NC(Me)₂), 33.8 (C(CH₃)₃), 32.6 (C(CH₃)₃), 32.3 (CH₃), 29.1 (C(CH₃)₃) ppm. Preparation of [Ca{N(SiMe₃)₂}]_n{K²-(Im^{tBu}NCONPh)Ca{N(SiMe₃)₂}} (4a)

In an argon-filled glovebox, to the toluene (5 mL) solution of calcium diiodide (186.9 mg, 0.636 mmol), a toluene (5 mL) solution of compound **1a** (200 mg, 0.636) and potassium bis(trimethylsilyl)amide (380.6 mg, 1.90 mmol) was added

dropwise at ambient temperature. The resulting reaction mixture was further stirred at room temperature for 12 hours. The white precipitate obtained from the reaction mixture was separated by filtration through a G4 frit. The solvent was evaporated under reduced pressure to obtain an off-white residue, which was washed with *n*-hexane (3 × 10 ml) and dried *in vacuo*. The title compound **4a** was re-crystallised from a mixture of THF and toluene (1 : 3) at −35 °C.

Yield 426 mg, 57%. ¹H NMR (400 MHz, C₆D₆): δ 7.80 (m, 2H, Ar), 7.29 (m, ³J_{H-H} = 8.0 Hz, 2H, Ar), 7.06 (m, 1H, Ar), 6.16 (s, 2H, HC=CH), 3.42 (thf), 1.40 (thf), 1.49 (s, 18 H, C(CH₃)₃) 0.43 (s, 18H, Si(CH₃)₃), 0.21 (s, 18H, Si(CH₃)₃) ppm. ¹³C{¹H} NMR (100 MHz, C₆D₆): δ 164.1 (C=O), 152.7 (NCN), 129.5 (Ar), 129.1 (Ar), 128.1 (Ar), 127.2 (Ar), 123.9 (Ar), 119.2 (Ar), 111.6 (HC=CH), 68.5 (NC(CH₃)₃), 57.8 (thf), 29.4 (C(CH₃)₃) 25.2 (thf), 6.16 (Si(CH₃)₃), 2.90 (Si(CH₃)₃) ppm. FTIR selected peaks (cm⁻¹): 1619 (C=O), 2954. (C₃₃H₆₄CaKN₆OSi₄) (752.42) Calc. C 52.68, H 8.57, N 11.17; found C 52.22 H 8.13, N 10.88.

5a: Compound **5a** was obtained as a minor product from the second crop solution after the crystals of **4a** were isolated. Yield 195 mg, 8%. ¹H NMR (400 MHz, C₆D₆): δ 7.81–7.68 (m, 2H, Ar), 7.31–7.27 (m, 2H, Ar), 7.14–7.08 (m, 1H, Ar), 6.12 (s, 2H, HC=CH), 3.57 (thf), 1.45 (thf), 1.42 (s, 18 H, C(CH₃)₃) 0.43 (s, 18H, Si(CH₃)₃), 0.21 (s, 18H, Si(CH₃)₃) 0.09 (s, 24H, OSi(CH₃)₂) ppm. ¹³C{¹H} NMR (100 MHz, C₆D₆): δ 168.1 (C=O), 156.3 (NCN), 129.8 (Ar), 129.3 (Ar), 128.0 (Ar), 127.6 (Ar), 125.1 (Ar), 120.2 (Ar), 115.4 (HC=CH), 66.5 (NC(CH₃)₃), 57.8 (thf), 28.4 (C(CH₃)₃) 25.2 (thf), 7.15 (Si(CH₃)₃), 3.76 (Si(CH₃)₃), 1.02 (OSi(CH₃)₂) ppm. X-Ray crystallographic studies of complexes **1a**, **1d**, **2b**, **2c**, **3a**, **4a**, **5a**

Single crystals of compounds **1a** and **1d** were grown from concentrated toluene under an inert atmosphere at 15 °C. Crystals of **2c** were grown from a concentrated solution of toluene at −35 °C, whereas single crystals of **2b**, **4a** and **5a** were grown from a mixture of THF and toluene (1 : 3) at −35 °C. For all the complexes, a crystal of suitable dimensions was mounted on a CryoLoop (Hampton Research Corp.) with a layer of light mineral oil and placed either at room temperature (for **1a**) or in a nitrogen stream at 150(2) K. All the measurements were made on an Agilent Supernova X-calibur Eos CCD detector with graphite-monochromatic Cu-Kα (1.54184 Å) radiation. The crystal data and structure refinement parameters are summarised in Table TS1 in the ESI.† The structures were solved by direct methods (SIR92)²⁷ and refined on *F*² by full-matrix least-squares methods using SHELXL-97.²⁸ Non-hydrogen atoms were anisotropically refined. H atoms were included in the refinement in calculated positions riding on their carrier atoms. No restraints were made for any of the complexes. The function minimised was $[\sum w(F_o^2 - F_c^2)^2]$ ($w = 1/[s^2(F_o^2) + (aP)^2 + bP]$), where $P = (\max(F_o^2, 0) + 2F_c^2)/3$ with $s^2(F_o^2)$ from counting statistics. The function *R*₁ and *wR*₂ were $(\sum ||F_o| - |F_c||)/\sum |F_o|$

and $[\sum w(F_o^2 - F_c^2)^2/S(wF_o^4)]^{1/2}$, respectively. The Diamond-3.0 program was used to draw the molecule. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no CCDC 1046050–1046056.

Conclusion

We have demonstrated the synthetic and structural details of potassium, lithium and calcium complexes of the imidazol-2-ylidene-*N'*-phenylureate ligand, which display various coordination modes such as κ¹, κ² and κ³. From the solid-state structures it is evident that not only are the nitrogen and oxygen atoms of the isocyanate building block coordinating, but also that the imidazolin-2-imine nitrogen atom takes part in a coordination with the potassium and calcium ions. Due to the larger size of the potassium and calcium ions and the multi-dentate nature of the ureate ligand, polymeric structures were obtained in most cases. However, by controlling the substituent as mesityl groups over the imidazol ring, a heterocubane core K₄O₄ was isolated in potassium complex **2b**.

Acknowledgements

This work is supported by the Science and Engineering Research Board (SERB), Department of Science and Technology (DST), India, under project no. (SB/S1/IC/045/2013). The instrumental facilities were provided by the Indian Institute of Technology Hyderabad (IITH). K.N. and J.B. thank the University Grants Commission (UGC), India, for their PhD fellowships. We sincerely thank Prof. Kazushi Mashima and Dr Hayato Tsurugi, Osaka University for their generous support. We thank reviewers to improve the manuscript.
