# Turning a "useless" ligand into a "useful" ligand: a magneto-structural study of an unusual family of $\mathrm{Cu}^{11}$ wheels derived from functionalised phenolic oximes $\dagger$ 

Jamie M. Frost, ${ }^{\text {a }}$ Robert J. Stirling, ${ }^{\text {a }}$ Sergio Sanz, ${ }^{\text {a }}$ Nidhi Vyas, ${ }^{\text {b }}$ Gary S. Nichol, ${ }^{\text {a }}$ Gopalan Rajaraman*b and Euan K. Brechin*a

#### Abstract

While the phenolic oximes ( R - $\mathrm{saOH}_{2}$ ) are well known for producing monometallic complexes of the type $\left[M^{\prime \prime}(\mathrm{R}-\mathrm{saOH})_{2}\right]$ with $\mathrm{Cu}^{\prime \prime}$ ions in near quantitative yield, their derivatisation opens the door to much more varied and interesting coordination chemistry. Here we show that combining the complimentary diethanolamine and phenolic oxime moieties into one organic framework ( $\mathrm{H}_{4} \mathrm{~L}_{1}$ and $\mathrm{H}_{4} \mathrm{~L}_{2}$ ) allows for the preparation and isolation of an unusual family of $\left[\mathrm{Cu}^{\prime \prime}\right]_{n}$ wheels, including saddle-shaped, single-stranded $\left[\mathrm{Cu}{ }^{11}{ }_{8}\right]$ wheels of general formula $\left[\mathrm{Cu}_{8}\left(\mathrm{HL}_{1}\right)_{4}(\mathrm{X})_{4}\right]^{n}[\mathrm{Y}]$ (when $n=0, \mathrm{X}=\mathrm{Cl}^{-}, \mathrm{NO}_{3}{ }^{-}, \mathrm{AcO}^{-}, \mathrm{N}_{3}{ }^{-}$; when $n=2+\mathrm{X}=$ $(\mathrm{OAc})_{2} /\left(2,2^{\prime}-\mathrm{bpy}\right)_{2}$ and $\left.\mathrm{Y}=\left[\mathrm{BF}_{4}\right]_{2}\right)$ and $\left[\mathrm{Cu}_{8}\left(\mathrm{HL}_{2}\right)_{4}(\mathrm{X})_{4}\right]\left(\mathrm{X}=\mathrm{Cl}^{-}, \mathrm{Br}^{-}\right)$, a rectangular $\left[\mathrm{Cu}_{6}\left(\mathrm{HL}_{1}\right)_{4}\right]$ wheel, and a heterometallic $\left[\mathrm{Cu}_{4} \mathrm{Na}_{2}\left(\mathrm{HL}_{1}\right)_{2}\left(\mathrm{H}_{2} \mathrm{~L}_{1}\right)_{2}\right]$ hexagon. Magnetic studies show very strong antiferromagnetic exchange between neighbouring metal ions, leading to diamagnetic ground states in all cases. DFT studies reveal that the magnitude of the exchange constants are correlated to the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral angles, which in turn are correlated to the planarity/puckering of the $\left[\mathrm{Cu}^{\prime \prime}\right]_{n}$ rings.

## Introduction

In the early days of molecular magnetism low nuclearity complexes containing $\mathrm{Cu}^{\mathrm{II}}$ ions were the focus of intense research efforts by synthetic chemists and theoreticians. ${ }^{1-5}$ The ease of synthesis of new compounds permitted the facile preparation of families of related molecules, providing simple ( $s=1 / 2$ ) model systems with which to test emerging theories and propose new experiments. ${ }^{1}$ In 1952 Bleaney and Bowers published a study of the magnetic properties of copper(II) acetate monohydrate, ${ }^{2}$ and some twenty three years later Hatfield and Hodgson published a magneto-structural correlation (MSC) demonstrating the linear relationship between the strength of the magnetic exchange interaction, $J$, and the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ bridging angle in an extended family of bis( $\mu$-hydroxido)copper(II) dimers. ${ }^{3,4}$ The first pre-designed construction of a molecule containing ferromagnetically coupled metal ions then followed

[^0]in 1978 with the molecule $\left[\mathrm{CuVO}(\mathrm{fsa})_{2} \mathrm{en}\right]\left(\right.$ where $(\mathrm{fsa})_{2} \mathrm{en}^{4-}$ is the bi-chelating ligand derived from the Schiff-base bis-(2'-hydroxy-3'-carboxybenzylidene)-1,2-diaminoethane) in which the magnetic orbitals on the constituent metal ions were rigorously orthogonal. ${ }^{5}$ The modern era has seen researchers turning their attention to increasingly more complex systems to examine, for example, spin frustration effects in Archimedean and Platonic solids such as $\mathrm{Cu}^{\mathrm{II}}$ cuboctahedra, ${ }^{6}$ and spin-electric coupling in antiferromagnetic $\left[\mathrm{Cu}^{\mathrm{II}}{ }_{3}\right]$ triangles resulting from the interplay between exchange, spin-orbit coupling and spin chirality. ${ }^{7}$

In the sixty or so years since the initial magnetic study of $\left[\mathrm{Cu}(\mathrm{OAc})_{2} \cdot \mathrm{H}_{2} \mathrm{O}\right]_{2}$ numerous different ligand types have been employed to construct molecules containing multiple $\mathrm{Cu}^{\text {II }}$ ions. ${ }^{8}$ However, one ligand type which can be almost entirely excluded from this list are the phenolic oximes $\left(\mathrm{R}-\mathrm{saOH}_{2}\right)$, since they have been shown to have an overwhelming propensity to form mononuclear complexes of the type $\left[\mathrm{Cu}(\mathrm{R}-\mathrm{saOH})_{2}\right]$ in near quantitative yields. ${ }^{9}$ Indeed their remarkable selectivity for copper in the $2+$ oxidation state has been exploited in industrial hydrometallurgy, with almost a quarter of the world's copper production involving salicylaldoxime-based ligands. ${ }^{9}$ This peculiar selectivity can be ascribed to the tendency of the ligands to form hydrogen bonded head-to-tail dimers mediated via intermolecular interactions between the oximic hydrogen atom on one unit and the phenolic oxygen

Fig. 1 The pre-organisation of phenolic oximes for the formation of [Cu" ${ }^{\text {I }}$ R-saoH $)_{2}$ ] species.
atom of its neighbour (Fig. 1). The resulting pseudo-macrocyclic cavity facilitates metal complexation, and selectivity for $\mathrm{Cu}^{\text {II }}$ arises from the goodness-of-fit of this metal cation with the cavity. ${ }^{10}$

Given the above, it is perhaps unsurprising that a search of the CSD reveals that there is only one example of a polymetallic $\mathrm{Cu}^{\text {II }}$ cage containing two or more metal ions stabilised solely by phenolic oximes. ${ }^{11}$ The complex, $\left[\mathrm{Cu}_{6}(\mathrm{~L} 3-2 \mathrm{H})_{3}\left(\mu_{3}-\mathrm{O}\right)\right.$ -$\left.\left(\mu_{3}-\mathrm{OH}\right)\right]\left(\mathrm{PF}_{6}\right)_{3}$, describes two $\left[\mathrm{Cu}^{\mathrm{II}}{ }_{3} \mathrm{O}\right]$ triangles linked by three "double-headed" phenolic oximes, and forms when the ligand: metal ratio employed in the reaction mixture is low; i.e. when the metal ions are present in excess. ${ }^{11}$ Perhaps the historical observation of a lack of variety in the coordination chemistry of $\mathrm{Cu}^{\mathrm{II}}$ with phenolic oximes has prevented others from investigating the chemistry further, but the formation of the hexametallic $\mathrm{Cu}^{\mathrm{II}}{ }_{6}$ species is clear evidence that more interesting structures remain undiscovered. Indeed the $\left[\mathrm{Cu}^{\mathrm{II}}{ }_{3} \mathrm{O}-\right.$ (oxime) ${ }_{3}$ ] triangles of the hexametallic cage are entirely analogous to the building blocks previously observed for $\mathrm{Mn}^{\text {III }}, \mathrm{Fe}^{\text {III }}$ and $\mathrm{Cr}^{\mathrm{III}}$; all of which present more varied and more interesting structural and physical chemistry. ${ }^{12}$ In order to address this "misperception" and to prove that polymetallic cages of $\mathrm{Cu}^{\mathrm{II}}$ can be built with this ligand type, we have adopted a synthetic approach which has already proven successful in Mn chemistry. ${ }^{13}$ While both salicylaldoxime and diethanolamine have very limited track records in $\mathrm{Cu}^{\text {II }}$ chemistry (a CSD search

Fig. 2 Generalised molecular structure of the pro-ligands $\mathrm{H}_{4} \mathrm{~L}_{1}(\mathrm{R}=$ $\mathrm{Me})$ and $\mathrm{H}_{4} \mathrm{~L}_{2}(\mathrm{R}=\mathrm{Et})$.
for the latter also returns only monometallic complexes) their combination into one single organic structural framework has the potential to transform the coordination abilities of both. Herein we show that this complimentary ligand approach to constructing novel polymetallic cluster compounds works rather well, by presenting the synthesis, structures and magnetic behaviour of a large and unusual family of $\mathrm{Cu}^{\mathrm{II}}$-based wheels constructed using the pro-ligands $\mathrm{H}_{4} \mathrm{~L}_{1}$ and $\mathrm{H}_{4} \mathrm{~L}_{2}$ (Fig. 2).

## Experimental

## Materials and physical measurements

All manipulations were performed under aerobic conditions using materials as received (reagent grade). The ligand $\mathrm{H}_{4} \mathrm{~L}_{1}$ \{1-(3-((bis(2-hydroxyethyl)amino)methyl)-2-hydroxy-5-methyl) phenyl)ethanone oxime\} was synthesised according to published procedures. ${ }^{13 a}$ The synthesis of $\mathrm{H}_{4} \mathrm{~L}_{2}\{1$-(3-((bis(2-hydro-xyethyl)amino)methyl)-2-hydroxy-5-methyl)propiophenoneoxime\} was achieved by adapting the literature preparation of $\mathrm{H}_{4} \mathrm{~L}_{1}$ (see the ESI $\dagger$ for full details). Variable temperature, solid-state direct current (dc) magnetic susceptibility data down to 5 K were collected on a Quantum Design MPMS-XL SQUID magnetometer equipped with a 7 T dc magnet. Diamagnetic corrections were applied to the observed paramagnetic susceptibilities using Pascal's constants.

## Synthesis

$\left[\mathrm{Cu}_{8}\left(\mathrm{HL}_{1}\right)_{4}(\mathbf{C l})_{4}\right](\mathbf{1}) . \mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(85.24 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}_{1}(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 h . Large green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor, over a period of 7 days. Elemental analysis (\%) calculated (found) for 1: C 38.06 (37.98), H 4.57 (4.36), N 6.12 (5.91).
$\left[\mathrm{Cu}_{8}\left(\mathrm{HL}_{1}\right)_{4}\left(\mathrm{NO}_{3}\right)_{4}\right](2) . \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}(121 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}_{1}(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 h . Green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of THF into the filtered mother liquor, over a period of 10 days. Elemental analysis (\%) calculated (found) for dried 2: C 37.13 (36.99), H 4.23 (3.98), N 8.50 (8.41).
$\left[\mathrm{Cu}_{8}\left(\mathrm{HL}_{1}\right)_{4}(\mathbf{O A c})_{4}\right](3) . \mathrm{Cu}(\mathrm{OAc})_{2} \cdot \mathrm{H}_{2} \mathrm{O}(90.54 \mathrm{mg}, 0.5 \mathrm{mmol})$, $\mathrm{H}_{4} \mathrm{~L}_{1}(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 h . Green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor, over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 3: C 40.99 (40.87), H 5.38 (4.94), N 5.54 (5.11).
$\left[\mathrm{Cu}_{\mathbf{8}}\left(\mathrm{HL}_{\mathbf{1}}\right)_{\mathbf{4}}(\mathbf{O A c})_{\mathbf{2}}\left(2,2^{\prime}-\mathrm{bpy}\right)_{2}\right]\left(\mathrm{BF}_{4}\right)_{\mathbf{2}}$ (4). A mixture of $\mathrm{Cu}\left(\mathrm{BF}_{4}\right)_{2}$ $(118.6 \mathrm{mg}, 0.5 \mathrm{mmol}), \mathrm{CH}_{3} \mathrm{COOH}(0.30 \mathrm{mg}, 0.5 \mathrm{mmol}) \mathrm{H}_{4} \mathrm{~L}_{1}$ $(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ and 2,2'-bipyridine ( $78.09 \mathrm{mg}, 0.5 \mathrm{mmol}$ ) were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1$, 25 mL ). After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 hours. Green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor, over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 4: C 44.21 (44.16), H 5.32 (5.24), N 6.87 (6.80).
$\left[\mathrm{Cu}_{\mathbf{8}}\left(\mathbf{H L}_{\mathbf{1}}\right)_{\mathbf{4}}\left(\mathbf{N}_{3}\right)_{\mathbf{4}}\right]$ (5). $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}(60 \mathrm{mg}, 0.25 \mathrm{mmol})$, $\mathrm{H}_{4} \mathrm{~L}_{1}(70 \mathrm{mg}, 0.25 \mathrm{mmol})$ and $\mathrm{KN}_{3}(40 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring $\mathrm{NEt}_{3}(0.15 \mathrm{~mL}, 1.05 \mathrm{mmol})$ was added and the solution stirred for a further 3 hours. Large green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 5: C 37.50 (37.42), H 5.64 (5.33), N 13.05 (12.84).
$\left[\mathrm{Cu}_{\mathbf{8}}\left(\mathbf{H L}_{2}\right)_{\mathbf{4}}(\mathbf{C l})_{4}\right](6) . \mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(85.24 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}_{2}(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 hours. Large green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 6: C 41.42 (41.18), H 5.32 (4.81), N 5.68 (5.17).
$\left[\mathrm{Cu}_{\mathbf{8}}\left(\mathrm{HL}_{2}\right)_{\mathbf{4}}(\mathrm{Br})_{\mathbf{4}}\right](7) . \mathrm{CuBr}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(85.24 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}_{2}(140 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring, $\mathrm{NEt}_{3}(0.3 \mathrm{~mL}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 hours. Large green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 7: C 37.52 (37.42), H 4.72 (4.55), N 5.68 (5.46).
$\left[\mathbf{C u}_{\mathbf{6}}\left(\mathbf{H L}_{\mathbf{1}}\right)_{\mathbf{4}}\right.$ ] (8). $\mathrm{Cu}(\mathrm{OMe})_{2}(60.28 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}_{1}$ $(70 \mathrm{mg}, 0.25 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring $\mathrm{NEt}_{3}$ $(0.30 \mathrm{ml}, 2.1 \mathrm{mmol})$ was added and the solution stirred for a further 3 h . Green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of diethyl ether into the filtered mother liquor over a period of 7 days. Elemental analysis (\%) calculated (found) for dried 8: C 44.89 (44.57), H 5.11 (4.88), N 7.48 (7.24).
$\left[\mathrm{Cu}_{4} \mathbf{N a}_{2}\left(\mathrm{HL}_{1}\right)_{2}\left(\mathbf{H}_{2} \mathbf{L}_{1}\right)_{2}\right]$ (9). $\mathrm{Cu}\left(\mathrm{BF}_{4}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O} \quad(118.6 \mathrm{mg}$, $0.5 \mathrm{mmol})$ and $\mathrm{H}_{4} \mathrm{~L}(140 \mathrm{mg}, 0.50 \mathrm{mmol})$ were dissolved in a solvent mixture of $\mathrm{MeOH}-\mathrm{MeCN}(1: 1,25 \mathrm{~mL})$. After 5 minutes of stirring $\mathrm{NaOMe}(216 \mathrm{mg}, 2 \mathrm{mmol})$ was added and the solution stirred for a further 3 hours. Green, block-like X-ray quality crystals were subsequently obtained by slow diffusion of hexane into the filtered mother liquor over a period of 12 days. Elemental analysis (\%) calculated (found) for dried 9: C 47.03 (46.91), H 5.71 (5.52), N 7.56 (7.22).

## X-ray crystallography

Single crystal X-ray diffraction data of 1-9 were collected at 100 K on a Agilent Technologies SuperNova at temperatures between 200 and 120 K. See Table $\mathrm{S} 1 \dagger$ and CIF files for full details. CCDC 991823-991828 and CCDC 1029554-1029556.

## Results and discussion

Complexes 1-7 (Fig. 3-5) share the same general structural framework, and so for the sake of brevity we describe $\mathbf{1}$ in detail and highlight any significant structural differences present in 2-7.

The metallic skeleton of complex 1 (Fig. 3) describes a saddle-like or basket shaped, single-stranded, octametallic wheel of approximate radius $7.3 \AA$, in which all eight $\mathrm{Cu}^{\mathrm{II}}$ ions are symmetry inequivalent. The coordination geometries of the Cu ions alternate between square planar ( $\mathrm{Cu} 1, \mathrm{Cu} 3, \mathrm{Cu} 5$, Cu 7 ) and square-based pyramidal (Cu2, Cu4, Cu6, Cu8, $\tau=$ $0.0743-0.0131$ ) as the wheel is circumnavigated. The $\mathrm{HL}_{1}{ }^{3-}$ ligands each bridge a total of four Cu ions: the oximic and phenolic moieties are $\mu$-bridging $\left(\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}, \sim 19-25^{\circ}\right.$;

Colour code, $\mathrm{Cu}=$ orange, $\mathrm{O}=$ red, $\mathrm{N}=$ blue, $\mathrm{C}=$ gold. (C) The metallic skeleton of 8 highlighting the bowlshape of the cluster. (D) The magnetic core of 8 showing the two different exchange interactions. (E/F) The two bridging modes of the $\mathrm{HL}_{1}{ }^{3-}$ ligand. H atoms omitted for clarity.
$\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}, \sim 16^{\circ}$ ), with one alkoxide arm of the diethanolamine moiety $\mu$-bridging $\left(\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}, \sim 18^{\circ}\right)$ and the other remaining protonated and terminally bonded ( $\mathrm{Cu}-\mathrm{O}, 2.317-2.433 \AA$ ). The remaining coordination sites on the square planar Cu ions are occupied by $\mathrm{Cl}^{-}$anions, which are H -bonded to the terminally bonded O -atoms of the diethanolamine arms ( $\mathrm{Cl} \cdots \mathrm{O}, \sim 3 \AA$ ). Each Cu ion is therefore linked to its neighbours by one alkoxide and one oximic - $\mathrm{N}-\mathrm{O}-$ moiety on one side, and by just one phenoxide on the other. The magnetic core is thus rather simple: $[\mathrm{Cu}-\mathrm{OR} / \mathrm{NO}-\mathrm{Cu}-\mathrm{OR}]_{4}$. Two of the $\mathrm{HL}_{1}{ }^{3-}$ ligands point above and two point below the plane of the bowl, each orientated inwards toward the centre of the bowl resulting in a (C‥C) separation of $\sim 3.5 \AA$. The closest intermolecular contacts are between the $\mathrm{Cl}^{-}$ions and the para- $\mathrm{Me}(\mathrm{Ph})$ groups of the $\mathrm{HL}_{1}{ }^{3-}$ ligands at a $(\mathrm{Cl} \cdots \mathrm{C})$ distance of $\sim 3.7 \AA$. The result is that molecules of $\mathbf{1}$ pack in a serpentine-like manner when viewed down the $b$-axis (Fig. S2 in the ESI $\dagger$ ).

The molecular structures of complexes 2-5 are shown in Fig. 4. Structural differences between 1 and 2-5, bar changes in the crystallographic/symmetry parameters (Table S1 in the ESI $\dagger$ ) and small changes in the bond lengths and angles, are limited to the terminally bonded $\mathrm{Cl}^{-}$ions being been replaced by chelating $\mathrm{NO}_{3}{ }^{-}$ions in 2 , chelating $\mathrm{CH}_{3} \mathrm{CO}_{2}{ }^{-}$ions in 3 and terminally bonded $\mathrm{N}_{3}^{-}$ions in 5 . In complex 4 two of the $\mathrm{Cl}^{-}$ ions have been replaced by chelating $\mathrm{CH}_{3} \mathrm{CO}_{2}^{-}$ions and two by chelating $2,2^{\prime}$-bpy molecules, with charge balance maintained through the presence of two $\mathrm{BF}_{4}{ }^{-}$counter anions. The chelating ligands change the geometry of the $\mathrm{Cu}^{\mathrm{II}}$ ions at these sites to distorted trigonal bipyramidal, meaning that the wheels 2-4 contain eight trigonal bipyramidal metal centres, with only complex 5 maintaining the four coordinate-five coordinate pattern seen in 1.

The introduction of an Et-group $\left(\mathrm{H}_{4} \mathrm{~L}_{2}\right)$ as opposed to a Megroup $\left(\mathrm{H}_{4} \mathrm{~L}_{1}\right)$ at the oximic carbon atom of the ligand appears to exert little structural effect, with complexes 6 and 7 being largely analogous to $\mathbf{1}$, with minor changes in bond lengths and bond angles. Complexes 1-7 all contain terminally bonded or chelating anions, introduced to the reaction mixture in the copper salt. In order to examine the effect of removing this anion, we repeated the synthesis employing the methoxide salt of $\mathrm{Cu}^{\text {II }}$. The reaction between anhydrous Cu $(\mathrm{OMe})_{2}$ and $\mathrm{H}_{4} \mathrm{~L}_{1}$ in a basic $\mathrm{MeOH}-\mathrm{MeCN}$ solution afforded the homoleptic, hexametallic wheel $\left[\mathrm{Cu}_{6}\left(\mathrm{HL}_{1}\right)_{4}\right]$ (8; Fig. 5). The metallic skeleton of $\mathbf{8}$ describes a single-stranded hexametallic, rectangular $\mathrm{Cu}^{\mathrm{II}}$ wheel. The asymmetric unit contains half the wheel, i.e. three Cu ions ( $\mathrm{Cu} 1-3$ ) and two $\mathrm{HL}_{1}{ }^{3-}$ ligands. The latter are triply deprotonated as before, but coordinate differently in 8 than in 1-7. One ligand bridges a total of four and the other a total of three metal centres with the oximic and phenolic moieties $\mu$-bridging ( $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}, \sim 37^{\circ}, \sim 48^{\circ}$; $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$; $\sim 108^{\circ}, \sim 113^{\circ}$ ) in both cases, as in 1-7. It is the alkoxide arms of the diethanolamine moiety of the two symmetry inequivalent ligands which behave differently: in one ligand, one arm is $\mu$-bridging ( $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}, 102.5^{\circ}$ ) with the other terminally bonded at the apical site of the Cu square-based pyramid $(\mathrm{Cu}-\mathrm{O}$, $2.35 \AA$ ); in the second, one arm is terminally bonded $(\mathrm{Cu}-\mathrm{O}$,
$2.4 \AA$ ) and one non-bonded, and H -bonding to the bridging alkoxide from a neighbouring $\mathrm{HL}^{3-}$ ligand $(\mathrm{O} \cdots \mathrm{O}, \sim 2.6 \AA)$. The coordination geometries of the Cu ions are thus mixed: Cu 2 is four coordinate and square planar, whilst Cu 1 and Cu 3 are five coordinate and square-based pyramidal ( $\tau=0.118$ and 0.0775 respectively). The metallic skeleton is near planar, as opposed to the puckered structures of 1-7, with the short and long edges of the rectangle measuring $\sim 3 \AA$ and $\sim 6 \AA$, respectively. As before, one pair of $\mathrm{HL}_{1}{ }^{3-}$ ligands points above and one pair below the plane of the wheel, with the aromatic rings being separated by approximately $3.5 \AA$. The closest intermolecular interactions occur between the para-Me $(\mathrm{Ph})$ groups of the ligand on one molecule and the terminally bonded O atom of the diethanolamine arms on its neighbour ( $\sim 3.7 \AA$, Fig. $\mathrm{S} 3 \dagger$ ).

A repetition of the reaction that produces complex 8, but using $\mathrm{Cu}\left(\mathrm{BF}_{4}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ in place of anhydrous $\mathrm{Cu}(\mathrm{OMe})_{2}$ and employing NaOMe instead of $\mathrm{NEt}_{3}$ results in the formation of $\left[\mathrm{Cu}_{4} \mathrm{Na}_{2}\left(\mathrm{HL}_{1}\right)_{2}\left(\mathrm{H}_{2} \mathrm{~L}_{1}\right)_{2}\right]$ (9; Fig. 6). The metallic skeleton of complex 9 also describes a hexametallic wheel, but on this occasion it is heterometallic, more hexagonal than rectangular, and non-planar. The asymmetric unit includes the $\mathrm{Cu}_{2} \mathrm{Na}$ trimeric moiety, (Cu1-Na1, $\sim 6.4 \AA$; Cu1-Na1', $\sim 3.2 \AA$ ) with the $\mathrm{Na} . . . \mathrm{Na}$ diameter of the wheel being $\sim 6.9 \AA$, and the closest

Fig. 6 The molecular structure of complex 9 viewed perpendicular (A) and parallel (B) to the $\mathrm{Cu}_{4} \mathrm{Na}_{2}$ "plane". Colour code, $\mathrm{Cu}=$ orange, $\mathrm{Na}=$ purple, $\mathrm{O}=$ red, $\mathrm{N}=$ blue, $\mathrm{C}=$ gold. (C) The metallic skeleton of 9 highlighting the bowl-shape of the cluster. (D) The magnetic core of 9 showing the two different exchange interactions. (E) The bridging mode of the $\mathrm{H}_{1} \mathrm{~L}^{3-}$ ligand (F) The bridging mode of the $\mathrm{H}_{1} \mathrm{~L}^{3-}$ ligand. H atoms omitted for clarity.
$\mathrm{Cu} . . . \mathrm{Cu}$ distance $\sim 4.9 \AA\left(\mathrm{Cu} 2 \ldots \mathrm{Cu} 2^{\prime}\right) . \mathrm{Cu} 1$ is five coordinate and trigonal bipyramidal ( $\tau=0.14$ ), whilst Cu 2 is four-coordinate and square planar in geometry. The ligands are of two types: $\mathrm{HL}_{1}{ }^{3-}$ and $\mathrm{H}_{2} \mathrm{~L}_{1}{ }^{2-}$ (Fig. 6E and 6F). The former bridges a total of four metal centres, with the oximic and phenolic moieties $\mu$-bridging $\left(\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu} ; \sim 50^{\circ} ; \mathrm{Cu}-\mathrm{O}-\mathrm{Cu}, \sim 112^{\circ}\right)$, one alkoxide arm of the diethylamine moiety is $\mu$-bridging between Cu 1 and $\mathrm{Na}^{\prime}$, with the second arm terminally bonded to Cu 1 and H -bonded to a neighbouring oximic O -atom ( $\sim 2.6 \AA$ ). The second ligand uses its oximic O -atom (O6) to bridge between Cu 1 and Na 1 ; its oximic N -atom also bonded to Cu 1 . The phenoxide O -atom $\mu$-bridges between Cu 2 and Na 1 , with both diethanolamine arms being terminally bonded to Na1. The $\mathrm{Na}^{+}$ions are six-coordinate and in distorted octahedral geometries. There are two intramolecular H-bonding interactions per molecule; between the H -atom of the protonated diol arm of one ligand and the oximic O -atom of its symmetry equivalent $\left(\mathrm{O} \cdots \mathrm{H}=\sim 2.6 \AA^{\circ}\right)$. The closest intercluster contacts are between the coordinated O-atom of one diethanolamine arm and the $\mathrm{CH}_{2}$ groups of a neighbouring arm ( $\sim 3.2 \AA$ A Fig. S4 and S5 in the $\mathrm{ESI} \dagger$ ). Complex 9 is clearly rather similar in structure to complex 8 , the major difference being the introduction of the larger $\mathrm{Na}^{+}$ions in the former. This has the effect of severely twisting of the $\mathrm{M}-\mathrm{M}-\mathrm{M}$ trimer of the asymmetric unit, from $\angle \mathrm{Cu}-\mathrm{Cu}-\mathrm{Cu}=166^{\circ}$ for 8 to $\angle \mathrm{Cu}-\mathrm{Cu}-\mathrm{Na}=\sim 146^{\circ}$ in 9 . This has two consequences for the latter complex: firstly the metallic skeleton becomes more bowl-shaped, and secondly there are no longer any coplanar ligands lying perpendicular to the $\mathrm{M}_{6}$ mean plane. Indeed the para- $\mathrm{Me}(\mathrm{Ph})$ moieties now point outward rather than inward as seen in all the previous cages (compare Fig. 5B and 6B).

It is difficult at this stage to definitively correlate the changes in syntheses, as summarised in Fig. 7, to the observed structural changes. The simplest reaction is that between $\mathrm{Cu}(\mathrm{OMe})_{2}$ and $\mathrm{H}_{4} \mathrm{~L}_{1}$, which produces $\left[\mathrm{Cu}_{6}(\mathrm{HL})_{4}\right](8)$ and MeOH . The same product results from reactions employing different alkoxide precursors. Thus it seems the alcohol produced does not bond to the $\mathrm{Cu}^{\mathrm{II}}$ ions. When the anion of the metal salt is changed to one that is commonly found to chelate, bond terminally or even bridge between metal centres, or if that anion is added separately to the reaction mixture (halide, pseudohalide, carboxylate), the nuclearity of the cage increases to $\left[\mathrm{Cu}_{8}\right]$ despite the fact that this anion is non-bridging. Much of this seems rather counter-intuitive at first: one might expect the removal of terminally bonded anions to promote increased bridging of $\mathrm{HL}_{1}{ }^{3-}$ and/or to encourage further deprotonation to $\mathrm{L}_{1}{ }^{4-}$. However this does not occur, and even the addition of an excess of base does not achieve this transformation. We can only surmise that the addition of a bonding anion forces a change in the metal geometry which in turn forces a change in the bonding mode of the ligand and thus to different cluster nuclearities and topologies. The introduction of the alkali metal ion $\mathrm{Na}^{+}$, in the form of NaOMe, suggests other heterometallic cages can be made by simply employing alternative group 1 or group 2 alkoxides, although we have not investigated this further.

Fig. 7 Summarising the effect changes in $\mathrm{CuX}_{2}$ starting material has on product formation with $\mathrm{H}_{4} \mathrm{~L}_{1 / 2}$.

A search of the CSD reveals that there are thirteen examples of O-bridged, single-stranded homo-metallic $\mathrm{Cu}^{\text {II }}$ wheels of nuclearity $\leq 8$ in the literature. Of these, seven are octametallic ${ }^{14-20}$ and six are hexametallic. ${ }^{21-26}$ There are many more examples of both octametallic and hexametallic singlestranded Cu wheels which contain bridging motifs that do not feature oxygen atoms. ${ }^{27}$ To the best of our knowledge there are no reported examples of single-stranded heterometallic wheels of nuclearity six with a $\mathrm{Cu}: \mathrm{M}$ (where M is an alkali metal cation) ratio of $4: 2$. Complexes $\mathbf{1 - 7}$ therefore become only the 12th examples of O-bridged single-stranded octametallic $\mathrm{Cu}^{\mathrm{II}}$ wheels, complex 8 only the 7th example of a single-stranded hexametallic $\mathrm{Cu}^{\mathrm{II}}$ wheel, and complex 9 the first example of a single-stranded heterometallic $\mathrm{Na} / \mathrm{Cu}^{\mathrm{II}}$ wheel. Apart from their rather beautiful structural aesthetics, molecular wheels have long held fascination for both chemists and physicists, since they can often act as model compounds for the study of quantum effects and spin frustration. ${ }^{28}$ and have recently been identified as potential candidates for quantum information processing. ${ }^{29}$

## Magnetochemistry

DC magnetic susceptibility. Dc magnetic susceptibility measurements were collected for complexes $1,2,8$ and 9 , in the $T=300-5 \mathrm{~K}$ temperature range in an applied field of $B=$ 0.1 T. The data are plotted in Fig. 8 as the $\chi_{\mathrm{M}} T$ versus $T$ products. Complexes 1 and 2 are representative examples of the two structurally different $\mathrm{Cu}_{8}$ wheels, with 8 and 9 being the $\mathrm{Cu}_{6}$ and $\mathrm{Cu}_{4} \mathrm{Na}_{2}$ wheels, respectively. The data for all four complexes are rather similar - showing a rapid decrease in $\chi_{\mathrm{M}} T$ with

Fig. 8 The magnetic susceptibility data, as $\chi_{M} T$, versus $T$ at $B=0.1 \mathrm{~T}$ for complexes 1 (red), 2 (green), 8 (blue) and 9 (magenta). The solid black lines are fits of the experimental data. The best fit 3 J model is shown for 8. See text for details.
decreasing temperature, indicative of the presence of very strong antiferromagnetic interactions between neighbouring $\mathrm{Cu}^{\mathrm{II}}$ ions, resulting in diamagnetic ground states (at $T=$ $110-220 \mathrm{~K}$ ) in all cases. We have used the programme ITOMAGFIT $^{30}$ which makes use of irreducible tensor operator algebra ${ }^{31}$ to block-diagonalise the spin-Hamiltonian in order to model the experimental data. In all cases the $g$-values of the $\mathrm{Cu}(\mathrm{II})$ ions were fixed to $g=2.2$. The resulting best-fit curves obtained in this way are shown as solid black lines in Fig. 8 with the corresponding best-fit parameters listed in Table 1. A schematic of the models employed is shown in Fig. 9. For the $\mathrm{Cu}_{8}$ clusters best-fit $J$-values reveal that the exchange through the $\mathrm{Cu}-\mathrm{O} / \mathrm{NO}-\mathrm{Cu}$ bridge is very large and negative $\left(J_{1}=-457\right.$ and $-302 \mathrm{~cm}^{-1}$ for 1 and 2 respectively), with the exchange through the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ bridge also antiferromagnetic but smaller in magnitude ( $J_{2}=-20.1$ and $-38.9 \mathrm{~cm}^{-1}$ for 1 and 2 respectively). The differences can be correlated to subtle differ-

Fig. 9 The magnetic cores of the representative $\mathrm{Cu}_{8}, \mathrm{Cu}_{6}$ and $\mathrm{Cu}_{4} \mathrm{Na}_{2}$ metal cores (left) and the models representing the exchange component of the spin-Hamiltonians which their experimental susceptibility data were fitted to (right). For the experimental fit of $9 J_{4}=0$.
ences in structure: a) the $\mathrm{Cu}-\mathrm{O}-\mathrm{N}-\mathrm{Cu}$ dihedral angles are flatter in $1\left(\sim 19,20,21,25^{\circ}\right)$ than in $2\left(\sim 23,23,24,24^{\circ}\right)$; b) the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angles in 1 are typically larger than $2\left(\sim 115-118^{\circ}\right.$ versus $\left.\sim 110-118^{\circ}\right)$. The former would be expected to make $J_{2}$ larger in $\mathbf{1}$, and the latter make $J_{1}$ larger in 2 , as observed. For complex 8, the best fit of the experimental data is afforded by a $3 J$ model, accounting for the single alkoxide bridge $\left(J_{1}\right)$ and the two NO/O bridges which display markedly different bridging angles (48.17, 37.47; $J_{2}$ and $J_{3}$ ). The best fit parameters obtained were $J_{1}=-107, J_{2}=-239$ and $J_{3}=-260 \mathrm{~cm}^{-1}$. This fit however is not unique and we were able to obtain several satisfactory fits using a $2 J$ model (see Table 1). Nevertheless, the parameters of the $3 J$ best fit are consistent with those obtained for 1 and 2 in which $J(\mathrm{O} / \mathrm{NO})>J(\mathrm{O})$ and with the larger torsion angle mediating weaker antiferromagnetic exchange. Complex 9 describes a wheel comprising two simple, non-interacting $\mathrm{Cu}(\mathrm{II})$ dimers in which we assume negligible interaction through the $\mathrm{Cu}-\mathrm{Na}-\mathrm{Cu}$ bridge. This model affords a best fit $J_{2}=$ $-271 \mathrm{~cm}^{-1}$. The exchange is again antiferromagnetic in nature, but somewhat larger than observed for 1,2 and 8 . A literature search reveals only three examples of dimers which feature $\mathrm{Cu}-\mathrm{O} / \mathrm{NO}-\mathrm{Cu}$ moieties, but on which no magnetic studies have been reported. ${ }^{32}$ There are several examples of polymetallic Cu systems featuring $\mathrm{Cu}-\mathrm{O} / \mathrm{NO}-\mathrm{Cu}$ bridging motifs, ${ }^{33}$ and all show the interaction to be strongly antiferromagnetic. The magnitude of the exchange interaction in purely alkoxo-bridged $\mathrm{Cu}(\mathrm{II})$ dimers varies enormously and is dependent on the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle, but in general they tend to be strongly antiferromagnetic with $J$ lying in the region -200
to $-1000 \mathrm{~cm}^{-1} .{ }^{34}$ A similar pattern is seen in purely oximato bridged $\mathrm{Cu}(\mathrm{II})$ dimers, where $J$ ranges from $-361 \mathrm{~cm}^{-1}$ to $-880 \mathrm{~cm}^{-1},{ }^{35}$ although in the vast majority of cases $J$ appears to lie in the region -600 to $-800 \mathrm{~cm}^{-1}$. In order to investigate the origin and magnitude of the exchange interactions seen in complexes 1, 2, 8 and 9 further we have turned to theory, and now discuss a computational DFT study.

## Theoretical studies

Computational details. Calculations were performed using the B3LYP ${ }^{36}$ functional, with Alhrich's triple- $\zeta \mathrm{TZV}^{37}$ basis set for the $\mathrm{Cu}(\mathrm{II})$ ions and SV basis sets for the remaining atoms, as implemented in the Gaussian $09^{38}$ suite of programs. The exchange constants between the $\mathrm{Cu}($ (I) ions were calculated as the energy difference between the high spin state ( $E_{\mathrm{HS}}$ ) using single determinant wave functions, and the low spin state ( $E_{\mathrm{BS}}$ ) using Noodleman's broken symmetry approach. ${ }^{39-42}$ The exchange Hamiltonians adopted are the same as those described in the experimental section above (Fig. 9). In complex 1 there are two unique exchange interactions denoted as $J_{1}$ and $J_{2}$, mediated via a $\mu$-phenoxo bridge and a $\mu$-alkoxo/ oxime bridge, respectively. Calculations yield $J_{1}=-45.0 \mathrm{~cm}^{-1}$ and $J_{2}=-320 \mathrm{~cm}^{-1}$. Both interactions are computed to be antiferromagnetic in nature with $J_{2}$ being very strong. To cross check, calculations were also performed using a diamagnetic substitution method whereby all metal centres not involved in the exchange interaction were replaced with diamagnetic Zn (II) ions. This method yielded a very similar set of $J$ values, $J_{1}=$ $-35.1 \mathrm{~cm}^{-1}$ and $J_{2}=-300 \mathrm{~cm}^{-1}$. Fitting of the experimental susceptibility data also yields similar $J$ values, indicating weak antiferromagnetic $J_{1}$ and strong antiferromagnetic $J_{2}$ interactions (see Table 1), as would be expected since their $\mathrm{Cu}-\mathrm{O}-$ Cu angles are rather similar $\left(115.8^{\circ}, 118.6^{\circ}\right)$. However their magnitude is much smaller than might be anticipated from previous magnetostructural correlations. ${ }^{43}$ This results from the puckering of the ring: the unpaired electron in $\mathrm{Cu}(\mathrm{II})$ is found in the $\mathrm{d}_{x^{2}-y^{2}}$ orbital and the buckled nature of the wheel results in the two magnetic orbitals (corresponding to the $J_{1}$ interaction) being in different planes (Fig. S6 $\dagger$ ), weakening the interaction. This is in stark contrast to the $J_{2}$ interactions where the oxime moiety forces the $\mathrm{d}_{x^{2}-y^{2}}$ orbitals to be in same plane, leading to a very strong interaction. The magnitude of exchange in $\mathrm{Cu}(\mathrm{II})$ complexes can be correlated directly to the energy gap between the symmetric and antisymmetric combinations of the $\mathrm{d}_{x^{2}-y^{2}}$ orbitals. The oxime bridge present in $J_{2}$ produces a complementarity effect whereby the $\pi^{*}$ orbitals of the oxime interacts with the antisymmetric combination (Fig. 10), leading to a larger energy gap and hence to stronger antiferromagnetic coupling.

The overlap integrals, computed as 0.08 and 0.20 for $J_{1}$ and $J_{2}$, respectively, confirm this. Computed spin density plots for complexes 1, 8, and 9 are shown in Fig. 11. The $\mathrm{Cu}(\mathrm{II})$ centres in complex 1 possess spin densities of $0.63[\mathrm{Cu}(1)]$ and 0.59 $[\mathrm{Cu}(2)]$, values substantially lower than the expected value of 1.0, revealing significant delocalisation (and hence strong exchange) of the unpaired spin onto the bridging ligands. The

Fig. 10 Schematic representation of the complementarity effect exhibited by the oxime bridge with symmetric and antisymmetric combinations of $d_{x^{2}-y^{2}}$ orbitals (left) and a representative MO diagram depicting the antisymmetric combination of the $d_{x^{2}-y^{2}}$ orbitals (right).

Fig. 11 B3LYP computed spin density plots of complex 1 (a), 8 (b) and 9 (c).
spin density on the bridging groups are also significant, 0.12 on the O -atom of the $\mu$-alkoxide $\left(J_{1}\right)$, and 0.16 on the O -atom of the $\mu$-alkoxide, and 0.13 and 0.10 for O and N atoms of the oxime bridge in the $J_{2}$ interaction.

For complex 2 calculations yield a similar set of exchange constants, although the $J_{2}$ interaction is computed to be slightly smaller (Table 1). The decrease in the magnitude of the $J_{2}$ interaction compared to complex 1 is found to correlate to the $\mathrm{Cu}-\mathrm{O}-\mathrm{N}-\mathrm{Cu}$ dihedral angle. In complex 2 the bulkier, chelating nitrate groups cause a twist in the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral leading to weaker $\mathrm{d}_{x^{2}-y^{2}}-\mathrm{d}_{x^{2}-y^{2}}$ overlap and a reduction in the $J$ values. The spin density on the $\mathrm{Cu}($ (I) centres in complex 2 are plotted in Fig. S7. $\dagger$

For complex 8 calculations yield $J_{1}=+5.53 \mathrm{~cm}^{-1}, J_{2}=$ $-25.9 \mathrm{~cm}^{-1}$ and $J_{3}=-120 \mathrm{~cm}^{-1}$. The $J_{1}$ interaction is computed to be weakly ferromagnetic in nature, in contrast to that fitted experimentally. Here the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle is relatively small ( $102.2^{\circ}$ ) and along with the large out-of-plane shift of the $\mathrm{O}-\mathrm{C}($ alkyl $)$ group from the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}-\mathrm{O}$ plane $\left(\sim 40.0^{\circ}\right)$ the geometry is approaching that theoretically predicted to mediate ferromagnetic exchange; ${ }^{44}$ the crossover area likely being the source of error in the theoretical calculation. $J_{2}$ and $J_{3}$ are antiferromagnetic in nature with $J_{3}$ being approximately five times larger. This is again correlated to the difference in the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral angle, with smaller angles yielding
stronger antiferromagnetic coupling. The magnitude of the $J_{2}$ and $J_{3}$ interactions are much smaller than that computed for complexes 1 and 2 due to the smaller ring size - the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-$ Cu moieties being far more twisted than that found in complexes 1 and 2. For complex 9 the computed exchange constants are $J_{2}=-95.8 \mathrm{~cm}^{-1}$ and $J_{4}=+0.08 \mathrm{~cm}^{-1}$. The former is consistent with that observed in previous complexes, and the latter as expected for an interaction mediated through a diamagnetic $\mathrm{Na}^{+}$ion. Computed overlap integrals ( 0.26 and 0.005 for $J_{2}$ and $J_{4}$, respectively) are consistent with this picture (Fig. $\mathrm{S} 8 \dagger$ ). In all four complexes the strongest antiferromagnetic coupling constant is underestimated by DFT, the differences being particularly obvious when the other $J$ values are small in magnitude. The underestimation of the exchange interactions in $\mathrm{Cu}(\mathrm{II})$ complexes by DFT has been highlighted previously, ${ }^{45}$ and is thus a limiting factor in the accurate estimation of absolute values.

Since the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral has been found to play an important role in determining the $J$ values in this family of complexes, we have developed a magneto-structural correlation based on a dimeric model of complex 9 shown in the inset of Fig. 12. By varying the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral angle $(x)$ [with the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle fixed] from $0-80^{\circ}$ an exponential correlation was found, with the smallest dihedral angles leading to the strongest AF exchange, and the largest dihedral angles leading to the weakest AF exchange. Fitting the data to the expression

$$
-J=A e\left[\frac{x}{t}\right]+y_{0}
$$

yields $y_{\mathrm{o}}=-608, A=262, t=-79.5$, revealing a switch from AF to F exchange at dihedral angles $>60^{\circ}$. Attempts are underway to isolate wheels with this large degree of puckering in order to test this theory.

Fig. 12 Magnetostructural correlation developed by DFT calculations by varying the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral angle in a model complex based on complex 9. The solid black squares are computed points and the red line the best fit to these points. The hollow blue circles are the DFT calculated values for the full structure, whilst the red circles are the experimentally fitted exchange constants.

## Conclusions

The simple reaction of $\mathrm{Cu}(\mathrm{II})$ salts with diethanolamine-functionalised phenolic oximes has resulted in seven new examples of single-stranded octametallic $\mathrm{Cu}($ II $)$ wheels, one new example of a single-stranded hexametallic $\mathrm{Cu}(\mathrm{II})$ wheel, and the first reported example of a single-stranded hexametallic mixedmetal $\mathrm{Na}_{2} \mathrm{Cu}_{4}$ wheel. The construction of polymetallic cages from ligand moieties normally associated with producing monometallic $\mathrm{Cu}(\mathrm{II})$ compounds is clear evidence that combining complimentary ligand types into one organic framework is a sensible methodology for building polymetallic cluster compounds. In each case the interaction between neighbouring metal ions was shown to be strongly antiferromagnetic. DFT calculations suggest the origin to be a complementarity effect due to the presence of the oxime bridge, in which smaller $\mathrm{Cu}-$ $\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ dihedral angles yield larger exchange constants, which are inherently linked to the planarity of the wheel. A magnetostructural correlation developed even suggests that such Cu (II) wheels can be made to display intramolecular ferromagnetic exchange if the $\mathrm{Cu}-\mathrm{N}-\mathrm{O}-\mathrm{Cu}$ torsion angles can be of the order of $60^{\circ}$ or larger. Current efforts are aimed at synthetic strategies to achieve just that.
