## Water-soluble Ir(III) complexes of deprotonated N-methylbipyridinium ligands: fluorine-free blue emitters†

Benjamin J. Coe,\*<sup>a</sup> Madeleine Helliwell,<sup>a</sup> Sergio Sánchez,<sup>a</sup> Martyn K. Peers<sup>b</sup> and Nigel S. Scrutton<sup>b</sup>

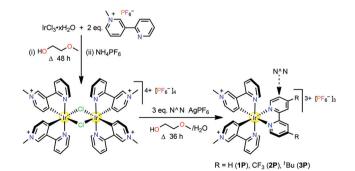

New blue or blue-green emitting iridium complexes have been synthesised with cyclometalating ligands derived from the 1-methyl-3-(2'-pyridyl)pyridinium cation. Efficient luminescence is observed in MeCN or aqueous solutions, with a large range of lifetimes in the  $\mu s$  region and relatively high quantum yields.

The creation of bright and stable blue emitting compounds is a major challenge in the development of light-emitting electrochemical cells and organic light-emitting diodes (OLEDs).<sup>1,2</sup> Iridium complexes have been investigated extensively due to their widely tunable and efficient luminescence.2-12 A common structural type is  $[Ir^{III}(C^N)_2(N^N)]^+$ , where  $C^N$  is a cyclometalating ligand like deprotonated 2-phenylpyridine, and N<sup>N</sup> is an α-diimine. A popular strategy to blue-shift the emission is to derivatise C^N with electron-withdrawing groups (often -F or -CF3) and/or place electron donors on N^N. Avoiding the use of fluorine is desirable to maximise the stability of the complexes in devices, and from an environmental perspective. Hence, we present an alternative approach, creating new fluorine-free IrIII luminophores by using 1-methyl-3-(2'-pyridyl)pyridinium to generate C^N. The quaternised nitrogen opposite the cyclometalating carbon is key to blue-shifting the emission.

Ir<sup>III</sup> complexes of C^N ligands derived from pyridinium species are extremely scarce.<sup>13</sup> Notably, these known complexes are not suitable for luminescence, but were prepared in the context of catalytic studies. Complexes with quaternary N units as part of N^N have been reported, but these groups are generally not strongly coupled electronically to the Ir<sup>III</sup> centre.<sup>14-17</sup> Remote ammonium groups have been attached to C^N<sup>18</sup> or acetylacetonate<sup>19</sup> ancillary ligands. Using Ir<sup>III</sup>

The new complexes 1–3 were synthesised by a standard approach, *i.e.* cleaving a cyclometalated chloride-bridged dimer with a N^N ligand (Scheme 1). The PF<sub>6</sub><sup>-</sup> and Cl<sup>-</sup> salts were characterised by <sup>1</sup>H NMR spectroscopy, electrospray mass spectrometry and elemental analyses (see ESI†). In addition, single-crystal X-ray structures have been solved for 1P·2MeCN and 3P·3Me<sub>2</sub>CO (Tables S1 and S3, Fig. S1 and S2, ESI†). As expected, both complexes exhibit pseudooctahedral coordination at Ir, with the pyridyl rings of the C^N ligands in a *trans* geometry (Fig. 1). Their chemical structures bear some resemblance to the widely studied complexes of N-heterocyclic carbenes derived from imidazolium species, although such complexes are typically neutral or only +1 charged.<sup>23–26</sup>

UV-vis absorption spectroscopic data are shown in Table 1. These spectra are almost unaffected by changing the counteranions and solvent. They are dominated by intense bands at  $\lambda < 320$  nm (Fig. S3 and S4, ESI†), assigned to  $\pi \to \pi^*$  and high

Scheme 1 Synthesis of the complex salts 1P–3P; their chloride counterparts 1C–3C were prepared by treating purified 1P–3P with  $[^nBu_4N]Cl$  in acetone.

complexes in bio-sensing/imaging<sup>20</sup> is often restricted by poor water solubility,<sup>21</sup> so increased positive charge is beneficial. Given this context and our general interest in photoactive complexes with quaternised pyridinium moieties,<sup>22</sup> we targeted unusual Ir<sup>III</sup> species combining attractive emission and solubility properties.

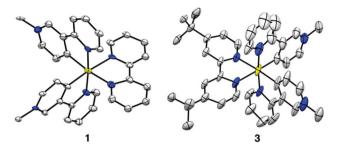

Fig. 1 Representations of the molecular structures of the complex cations in 1P-2MeCN and 3P-3Me<sub>2</sub>CO, with the PF<sub>6</sub><sup>-</sup> anions, solvent molecules and H atoms removed for clarity (50% probability ellipsoids).

energy metal-to-ligand charge-transfer (MLCT) transitions, involving both the C^N and N^N ligands. Weaker bands ( $\lambda_{max}$ ≈ 350-356 nm) are observed also. Cyclic voltammograms of 1P-3P in MeCN (Fig. S5, Table S2, ESI†) show an irreversible oxidation, formally assigned to a IrIV/III couple. The reductive region includes multiple irreversible processes, and a sharp return peak is observed for 1P and 3P, indicating adsorption onto the electrode surface.

Excitation at 315-400 nm in deoxygenated and oxygenated MeCN or aqueous solutions leads to bright blue (1 and 3) or blue-green (2) luminescence (Table 1). The spectra show significant fine structure, indicating primarily ligand-centred emission. As for the absorption spectra, changing the counteranion and solvent has only slight effects, and the excitation profiles remain constant in all cases while monitoring at all the emission maxima. The spectra are very similar for R = H or <sup>t</sup>Bu ( $\lambda_{\rm em}$  = 468–474 nm), but shifted significantly to lower energy when R = CF<sub>3</sub> ( $\lambda_{em}$  = 494). The fact that replacing H with tBu has little effect while -CF3 groups give a red-shift suggests that the character of the emitting state varies. The almost identical spectra of 1 and 3 (Fig. 2) indicate mainly <sup>3</sup>LC emission involving C^N with little 3MLCT contribution. However, the red-shift for 2 suggests that the emission is associated with N^N. The quantum yields  $\phi$  are not affected significantly by the counter-anions under deoxygenated conditions, but are substantially enhanced when R = CF<sub>3</sub> or <sup>t</sup>Bu  $(\phi \approx 42\text{-}45\%)$  as opposed to H  $(\phi \approx 24\text{-}27\%)$ . In oxygenated conditions, 2 shows the largest  $\phi$  values. All complexes have

emission lifetimes  $\tau$  in the  $\mu$ s region, covering a large range of values (ca. 1-12 μs), with monoexponential decay kinetics. 1C and 3C show relatively long  $\tau$  values in water, considerably longer than for 2C (Fig. 3).

Communication Dalton Transactions

The observed blue emissions from the fluorine-free complexes 1 and 3 are remarkable since, as mentioned above, decorating the C^N ligands with F or fluorinated groups is a common strategy to blue-shift the emission of this type of complex. The influence of the pyridinium fragment located para to the cyclometalating carbon is clearly shown by comparing the emission properties of 3P ( $\lambda_{\rm max}$  = 470 nm,  $\phi_{\rm deox}$  = 43%,  $\tau_{\rm deox}$  = 3.8 ms) with other reported complexes [Ir<sup>III</sup>(C^N)<sub>2</sub>{4,4'-(^1Bu)<sub>2</sub>bpy}]<sup>+</sup>. When using the heavily fluorinated cyclometalating ligand derived from 2-(2,4-difluorophenyl)-5-trifluoromethylpyridine, the emission in MeCN ( $\lambda_{\rm max}$  = 470 nm,  $\phi_{\rm deox}$  = 68%,  $\tau_{\rm deox}$  = 2.3 ms) is similar to that of 3P.<sup>27</sup> On the other hand, when C^N is deprotonated 2-phenylpyridine, the emission in MeCN is red-shifted strongly ( $\lambda_{\rm max}$  = 581 nm) with a lower  $\phi_{\rm deox}$  (24%) and shorter  $\tau_{\rm deox}$  (0.56 ms).<sup>28</sup>

The singlet ground  $(S_0)$  and lowest triplet excited  $(T_1)$  states of 1-3 were optimised by using density functional theory (DFT) (Fig. S6-S9, Tables S3-S8, ESI†). The calculated ground-state structures for 1 and 3 reproduce well the X-ray crystallographic ones. The LUMO is located on the C^N (69-90%) and N^N (6-27%) ligands. The HOMO is located at the Ir atom (50-55%) and the C^N ligands (40-46%), and is essentially invariant. Such relatively high C^N contributions are consistent with the irreversible oxidations observed by cyclic voltammetry (see above). The spectra simulated by time-dependent DFT agree relatively well with those measured. The weak low energy bands are due to a single transition for 1 and 3, a mixture of HOMO → LUMO and HOMO → LUMO+1 (347 nm, 1) or HOMO  $\rightarrow$  LUMO (348 nm, 3). For 2, transitions occur at 342 nm (HOMO  $\rightarrow$  LUMO+1) and 336 nm (HOMO-2  $\rightarrow$ LUMO), with the latter being ca. 5-fold more intense. These results indicate <sup>1</sup>MLCT character with <sup>1</sup>ML'CT and also <sup>1</sup>LL'CT for 1 and 2 ( $L = C^N$ ;  $L' = N^N$ ).

The  $T_1$  geometries resemble the  $S_0$  ones, except that 1 and 3 now have unequal Ir–C and (chemically equivalent) Ir–N distances, while in 2, these pairs of distances are equal. The calculated emission energies (Table 2) follow the experimental trend (1  $\approx$  3 > 2). The spin densities for the  $T_1$  state (Fig. 4) show mainly  $^3$ LC involving one C^N ligand with some  $^3$ MLCT contribution for 1 and 3. In contrast, for 2, the spin density is located on N^N largely, indicating that the emission has  $^3$ L'C character with some  $^3$ ML'CT. Therefore, on excitation from the C^N/Ir-centred HOMO–2 to the C^N-centred LUMO (336 nm transition) in 2, there is efficient inter-ligand energy transfer to

the emitting  $^3$ L'C excited state of N^N. Such energy transfer is expected if the  $^3$ L'C state lies below the  $^3$ MLCT. $^{29}$  In 2, the presence of the electron-withdrawing  $^-$ CF $_3$  groups stabilises the  $\pi^*$  orbitals of the N^N ligand, lowering the energy of the  $^3$ L'C state.

To conclude, using 1-methyl-3-(2'-pyridyl)pyridinium to generate C^N affords new water-soluble Ir<sup>III</sup> complexes. Their excited-state and emissive behaviour can be switched between two types by modifying N^N. The bright blue emission in MeCN and water of the fluorine-free complexes 1 and 3 suggests potential uses in highly efficient OLEDs or bioimaging. The tunability of the emission properties is shown, not only by the emission maxima, but also in the range of quantum yields (ca. 5–45%) and lifetimes, from quite short (ca. 1  $\mu$ s) to relatively long (ca. 12  $\mu$ s). Much further scope exists for modifying properties, for example by using groups other than methyl on the quaternised N atom.

We thank the EPSRC for support (grant EP/J018635/1), and the BBSRC for a PhD studentship (M.K.P.). N.S.S. is supported by an EPSRC Established Career Fellowship (grant EP/J020192/1) and was funded by a Royal Society Wolfson Merit Award. We thank Dr Louise S. Natrajan and Michael B. Andrews for assistance with the luminescence measurements.
