Enhanced visible and near infrared emissions via Ce$^{3+}$ to Ln$^{3+}$ energy transfer in Ln$^{3+}$-doped CeF$_3$ nanocrystals (Ln = Nd and Sm)$^\dagger$

Tuhin Samanta, Shyam Sarkar, Venkata. N. K. B. Adusumalli, Athma E. Praveen and Venkataramanan Mahalingam$^*$

We report the enhancement of both visible and near infrared (NIR) emissions from Nd$^{3+}$ ions via Ce$^{3+}$ sensitization in colloidal nanocrystals for the first time. This is achieved in citrate capped Nd$^{3+}$-doped CeF$_3$ nanocrystals under ultraviolet (UV) irradiation ($\lambda_{\text{ex}} = 282$ nm). The lasing transition ($^{4}F_{3/2} \rightarrow ^{4}I_{11/2}$) at 1064 nm from Nd$^{3+}$-doped CeF$_3$ nanocrystals has much higher emission intensity via Ce$^{3+}$ ion sensitization compared to the direct excitation of Nd$^{3+}$ ions. The nanocrystals were prepared using a simple microwave irradiation route. Moreover, the study has been extended to Sm$^{3+}$-doped CeF$_3$ nanocrystals which show strong characteristic emissions of Sm$^{3+}$ ions via energy transfer from Ce$^{3+}$ ions. The energy transfer mechanism from Ce$^{3+}$ to Nd$^{3+}$ and Sm$^{3+}$ ions is proposed.

1. Introduction

There is a surge in research interest towards developing lanthanide (Ln$^{3+}$)-doped nanomaterials as they show sharp luminescence signals with longer excited state lifetimes (in the range of $\mu$s to ms). In addition, Ln$^{3+}$ ions show luminescence peaks over a wide electromagnetic spectrum. Particularly interesting are those emitting in the near-infrared (NIR) region i.e. the spectrum with the wavelength range of 700 to 2100 nm. NIR luminescence of lanthanide ions (Ln$^{3+}$) finds applications in NIR LED technology, lasers, solar energy conversion, medical science and telecommunication.$^{1-4}$ For example, Ln$^{3+}$ ions such as Er$^{3+}$, Nd$^{3+}$, Tm$^{3+}$ and Ho$^{3+}$ have characteristic emissions in the NIR region and can be used as active materials for developing optical amplifiers.$^{5-7}$ In addition, NIR emission is quite valuable for biological applications because of lower scattering from the body than visible photons, low auto-fluorescence, deep penetration and being transparent to biological tissues.$^{8-11}$ However, Ln$^{3+}$ ions in aqueous media show very weak emission intensities owing to their low molar absorption coefficients (2–10 M$^{-1}$ cm$^{-1}$), which is attributed to both spin- and parity-forbidden 4f–4f transitions of Ln$^{3+}$ ions.$^{12-14}$ In addition, nonradiative transitions are very efficient in aqueous medium leading to further reduction of luminescence efficiency. One way to improve the luminescence efficiency is via an antenna effect, where typically an organic fluorophore possessing a high absorption coefficient is used as a sensitizer for Ln$^{3+}$ ions. The organic fluorophore transfers the absorbed energy to Ln$^{3+}$ ions leading to an enhanced luminescence quantum efficiency of Ln$^{3+}$ ions. However, most of the reports on the antenna effect are restricted to Ln$^{3+}$ complexes.$^{15,16}$ Moreover, organic molecules generally photobleach and are relatively less stable. On the other hand, Ce$^{3+}$ ions can be used as a sensitizer as they possess a high absorbance coefficient ($\sim 10^{18}$ cm$^{-1}$) due to allowed 4f–4f transitions.$^{17-20}$

The optical characteristics of Ce$^{3+}$ ions for efficient energy transfer are mainly attributed to two reasons: broad emission leading to better overlapping with absorption bands of other Ln$^{3+}$ ions and faster luminescence decay.$^{21-24}$ However, sensitization of luminescence via Ce$^{3+}$ ions is mostly restricted to visible emission of Tb$^{3+}$ ions and to some extent Dy$^{3+}$ ions.$^{25,26}$ Recently, we have used Ce$^{3+}$ ions for sensitizing Tm$^{3+}$ ions to obtain single band blue emission from NaYF$_4$ nanocrystals.$^{27}$

Our objective is to sensitize NIR emissions using Ce$^{3+}$ ions. Among NIR emitting Ln$^{3+}$ ions, Nd$^{3+}$ and Sm$^{3+}$ are interesting for the following reasons. For example, Nd$^{3+}$ ions show an important laser transition at 1064 nm (e.g. Nd$^{3+}$-doped Y$_2$Al$_2$O$_12$)$^{28-30}$ In fact the 1064 nm is used for achieving 532 nm via second harmonic generation. Furthermore, this emission due to the transition from $^{4}F_{3/2} \rightarrow ^{4}I_{11/2}$ energy levels falls well in the second “human optical window” (1000–1350 nm).$^{31-34}$ Similarly, Sm$^{3+}$ ions show two emissions in this optical window (near 1020 and 1150 nm) in addition to a strong emission at 940 nm. Moreover, the emission of Nd$^{3+}$ shows remarkable thermal sensitivity leading to their use as...
sub-tissue thermal sensors. However, both Nd3+ ions and Sm3+ ions show sharp f-f absorption which are difficult to pump. Although there are quite a few reports on Ce3+ to Nd3+ energy transfer, they are mostly restricted to a glass matrix. In fact, to our knowledge there are no reports on Ce3+ sensitized NIR emissions from Nd3+ or Sm3+ ions in colloidal nanocrystals, particularly in aqueous milieu. This is important as there is increasing demand for NIR emitting materials for biological imaging applications. Furthermore, colloidal nanocrystals can easily be coated or incorporated in sol–gel systems which is helpful for thin film device fabrication.

In this article, we report enhanced visible and NIR luminescence from Nd3+-doped CeF3 nanocrystals via Ce3+ sensitization. The lasing transition ($^4I_{11/2} \rightarrow ^4I_{15/2}$) at 1064 nm from Nd3+-doped CeF3 nanocrystals has shown emission strength about 3 times higher compared to that of the direct excitation of Nd3+ ions. Similarly, strong emissions in the NIR region are observed for Sm3+-doped CeF3 nanocrystals. We emphasize that all these are achieved from water and DMSO dispersible colloidal nanocrystals which can be useful for bioimaging applications.

2. Experimental section

2.1. Materials

Cerium nitrate [Ce(NO3)3, 99.98%], neodymium oxide [Nd2O3, 99.99%], samarium nitrate [Sm(NO3)3, 99.99%], trisodium citrate (>98%), sodium tetrafluoroborate (98%) and absolute ethanol were purchased from Sigma Aldrich. All chemicals were of analytical grade and used without further purification. Double distilled water was used throughout the synthesis and characterization.

2.2. Synthesis

Citrate functionalized Ln3+-doped CeF3 nanocrystals were prepared by a simple microwave assisted method. Briefly, 0.95 mmol of Ce(NO3)3 and 0.05 mmol of Nd(NO3)3 were taken in a 100 ml round bottom flask and completely dissolved in 15 ml of double distilled water. To this clear aqueous solution 1.5 mmol NaBF4 and 4 mmol trisodium citrate (TSC) were added and stirred until complete dissolution. The mixture was magnetically stirred for 15 minutes at room temperature. Finally the mixture was transferred to a 30 ml vial, used for microwave synthesis. The synthesis was carried out using the Anton Parr 300 microwave reactor. The vial was tightly sealed with a Teflon cap and the reaction was carried out at 180 °C for 10 minutes and then cooled to room temperature. The product was collected by centrifugation and washed thrice with absolute ethanol. It should be noted that the microwave experiments were carried out in temperature control mode. Simultaneous gas jet cooling (3–5 bar) during microwave irradiation was performed by using compressed air (6 bar). All microwave experiments were carried out using magnetic stirring at a rate of 600 rpm. The same protocol was used for the synthesis of citrate capped Sm3+-doped CeF3 nanocrystals. [0.97 mmol of Ce(NO3)3 and 0.03 mmol of Sm(NO3)3 in 15 mL double distilled water.]

2.3. Characterization

Powder X-ray diffraction (PXRD) measurements were performed on a Rigaku-smartlab diffractometer with Cu Kα operating at 70 kV and 35 mA at a scanning rate of 1° min−1 in the 2θ range from 20° to 80°. The samples were completely powdered and spread evenly on a quartz slide. TEM measurement was carried out using a high resolution FEG transmission electron microscope (JEOL, JEM 2100F) with a 200 keV electron source. Briefly, a drop of the CeF3 nanocrystals in water was taken on a strong carbon coated 300 mesh Cu grid and dried in air. The FT-IR spectra were obtained with a Perkin Elmer Spectrum RX1 spectrophotometer with the KBr disk technique in the range of 400–4000 cm−1. Thermogravimetric analysis was performed using the Mettler Toledo TGA 851 instrument under a N2 atmosphere at a heating rate of 10° min−1. The photoluminescence measurements were performed with the Horiba Jobin Yvon Fluorolog. All the emission spectra were recorded using the steady state 450 W Xe lamp as the excitation source. The luminescence lifetime measurements were performed using the Horiba Jobin Yvon Fluorolog machine with a pulsed Xe source of 150 W.

3. Results and discussion

3.1. Phase and structure

The phase analysis of the Ln3+-doped CeF3 (Ln = Nd and Sm) nanocrystals was performed using powder X-ray diffraction (XRD) measurements. Fig. 1 shows the XRD pattern of the Nd3+-doped CeF3 nanocrystals along with that of a standard reference. The peaks are matched well with that of the standard CeF3 (ICSD PDF Card no. 00-038-0452) suggesting the formation of a pure hexagonal phase. The

![Fig. 1. Powder XRD patterns of (a) Nd3+-doped CeF3 nanocrystals and (b) standard hexagonal CeF3 crystals (ICSD PDF Card No-00-038-0452).](image-url)
miller indices for each peak are shown above the corresponding peaks.

The average crystallite size is found to be 8.5 nm as calculated using the Debye–Scherrer equation, 

\[ t = \frac{(0.9 \lambda)}{\beta \cos \theta} \]

where \( t \) stands for average crystallite size, \( \lambda \) denotes the wavelength (\( \lambda = 1.5418 \text{ Å} \)) of incident X-ray, \( \beta \) denotes the corrected full width at half maximum (FWHM) and \( \theta \) denotes the diffraction angle. Lattice parameters of Nd\(^{3+}\)-doped CeF\(_3\) nanocrystals from XRD are found to be \( a = b = 7.1024, c = 7.2612 \) and \( \alpha = \beta = 90^\circ, \gamma = 120^\circ \). The hexagonal phase CeF\(_3\) nanocrystals adopt the same structure as LaF\(_3\), and the space group of these two crystals is \( P\overline{3}c1 \). The highest point group of this structure is \( D_{3d} \). In this structure, the anion ligand number is 12, i.e. each cation is surrounded by 12 anions. The cation sits at the center of an icosahedron. Twelve fluorides are close: four at the bottom corners of the icosahedron, four in the faces of the icosahedron, and four at the top corners of the icosahedron. The cation can be considered as 12 coordinate. The schematic of the unit cell crystal structure of hexagonal CeF\(_3\) obtained using the visualization for electronic and structural analysis (VESTA) program is shown in Fig. 2. The atomic coordinates \((x, y, z)\) used for the calculations are used from the reported literature\(^49\) and shown in Table S1 (see the ESI†).

3.2. Morphology analysis

The morphology of the citrate-functionalized Nd\(^{3+}\)-doped CeF\(_3\) nanocrystals is obtained by transmission electron microscopy (TEM) as shown in Fig. 3. From the TEM image the formation of oval shaped nanocrystals is clear. The average aspect ratio of the Nd\(^{3+}\)-doped CeF\(_3\) nanocrystals is found to be approximately 0.8 (length = 20 nm and breadth = 16 nm). For the semi-quantitative analysis of the elements present in the Nd\(^{3+}\)-doped CeF\(_3\) nanocrystals energy-dispersive X-ray (EDX) analysis was performed. The EDX analysis spectrum of Nd\(^{3+}\)-doped CeF\(_3\) nanocrystals are shown in Fig. S1 (see the ESI†). It confirms the presence of Ce, F, and Nd in the sample.

3.3. Surface functionalization

The high dispersibility of the citrate functionalized CeF\(_3\) nanocrystals in water suggests the binding of citrate ions to the surface of the nanocrystals which is supported by the FTIR analysis. The FTIR spectra of citrate capped CeF\(_3\) nanocrystals along with pure trisodium citrate molecules are shown in Fig. 4. For the free TSC, major peaks are observed near 3453, 2985, 1600 and 1399 cm\(^{-1}\). The strong and broad stretching vibration band centered at 3448 cm\(^{-1}\) is assigned to O–H in TSC and the peak at 2952 cm\(^{-1}\) is attributed to the methylene (CH\(_2\)) stretching vibrations of the alkyl chains of TSC. The band at 1600 cm\(^{-1}\) is assigned to the C=O asymmetric stretching vibrations of the alkyl chains of TSC. In the case of citrate capped Nd\(^{3+}\) doped CeF\(_3\) the band at 1399 cm\(^{-1}\) is due to symmetric stretching vibrations of C–O in the –COO\(^-\) group of the TSC.\(^50\)
CeF$_3$ nanocrystals, all the characteristic peaks for TSC molecules are observed, however the C=O stretching frequency is shifted towards a lower wavenumber (at 1590 cm$^{-1}$) which clearly indicates the binding of the TSC ligand onto the surface of the Nd$^{3+}$ doped CeF$_3$ nanocrystals.

To further confirm the citrate functionalization onto the surface of CeF$_3$ nanocrystals, TGA analysis was conducted. The TGA curves for both citrate capped CeF$_3$ nanocrystals and pure TSC are shown in Fig. S2, (see the ESI†). For the free TSC the major weight loss is noted from 250 °C due to the decomposition of TSC molecules. For the citrate functionalized CeF$_3$ nanocrystal, the onset of decomposition is shifted to the higher temperature (∼275 °C) which further confirms that the citrate molecules are strongly attached to the surface of the CeF$_3$ nanocrystals. The wt% of citrate molecules attached to the CeF$_3$ is close to 3.12% as calculated from the weight loss from the TGA analysis. Further confirmation for the attachment of the citrate ligands to the nanocrystals comes from the high stability of the nanocrystals in water. The dispersion of the nanocrystals was relatively stable in water for more than 10 hours. The photoluminescence study suggests that the luminescence intensity of Nd$^{3+}$ ions reduced by only ∼30% after 10 hours. The digital images of the colloidal dispersion along with the corresponding emission spectra are shown in Fig. S3.†

### 3.4. Optical properties

Photoluminescence (PL) studies have been carried out for the colloidal 0.1 wt(%) Nd$^{3+}$-doped CeF$_3$ nanocrystals in water. Upon excitation at 282 nm, the nanocrystal dispersion shows visible and NIR emissions as shown in Fig. 5. The prominent band in the visible region is at 693 nm, which is assigned to the $^3$I$_{15/2} \rightarrow ^4F_{7/2}$ transition. In addition, the nanocrystal dispersion shows characteristic NIR bands of Nd$^{3+}$ ions at 1062 and 1339 nm in water, which are assigned to the $^4F_{3/2} \rightarrow ^4I_{11/2}$ and $^4F_{3/2} \rightarrow ^4I_{13/2}$ transitions, respectively. The most intense band at 1062 nm is potentially suitable for application in laser emission and telecommunication. The inset of Fig. 5 displays the excitation spectrum which shows an intense broad peak at 282 nm by monitoring the emission at 1062 nm. This peak is due to the $4f5d \rightarrow 5f$ electronic transition of Ce$^{3+}$ ions. This confirms the energy transfer from Ce$^{3+}$ to Nd$^{3+}$ ions. To further verify the occurrence of energy transfer, we prepared Nd$^{3+}$-doped (5 mol%) LaF$_3$ nanocrystals using the same synthesis protocol. Upon excitation at 280 nm, no characteristic emission from Nd$^{3+}$ ions is observed confirming the energy transfer from Ce$^{3+}$ to Nd$^{3+}$ in Nd$^{3+}$-doped CeF$_3$ nanocrystals (see Fig. S4†). To understand the energy transfer efficiency, PL spectra of Nd$^{3+}$-doped CeF$_3$ nanocrystals were collected at direct excitation (514 nm) and 282 nm excitation. From Fig. 6, it is clear that upon 282 nm excitation the visible emission and NIR emission intensity increases by two and three times, respectively, compared to that of direct excitation. These results strongly suggest that efficient energy transfer occurs from Ce$^{3+}$ to Nd$^{3+}$ ions.

We have extended our study to check whether energy transfer from Ce$^{3+}$ ions to Sm$^{3+}$ ions is possible. The 3 mol(%) Sm$^{3+}$-doped CeF$_3$ nanocrystals were prepared using identical reaction conditions and characterized by XRD analysis. The XRD pattern suggests the formation of pure hexagonal phase CeF$_3$ nanocrystals as shown in Fig. S5.† The PL and excitation spectra of Sm$^{3+}$ (3%)-doped CeF$_3$ nanocrystals are shown in Fig. 7. Upon 280 nm excitation the dispersion of Sm$^{3+}$-doped CeF$_3$ nanocrystals in DMSO shows intense peaks at 559, 593, 639 and 702 nm which are assigned to $^4G_{5/2} \rightarrow ^6H_{5/2}$, $^4G_{5/2} \rightarrow ^6H_{7/2}$, $^4G_{5/2} \rightarrow ^6H_{9/2}$ and $^4G_{5/2} \rightarrow ^6H_{11/2}$ transitions, respectively. The $^4G_{5/2} \rightarrow ^6H_{9/2}$ transition at 560 nm has a magnetic dipole character. The intensity ratio of $\frac{I(^4G_{5/2} \rightarrow ^6H_{9/2})}{I(^4G_{5/2} \rightarrow ^6H_{5/2})}$ is 1.05 which indicates lower polarizability of the chemi-
3.5. Energy transfer mechanism

The proposed energy transfer mechanism between Ce$^{3+}$ to Nd$^{3+}$ ions and Sm$^{3+}$ ions is schematically shown in Fig. 8. Upon 282 nm excitation, Ce$^{3+}$ ions get excited from 4f$^1$ to 4f$^5$d$^1$ levels. A radiative energy transfer occurs from the relaxed lowest 4f$^5$d level of Ce$^{3+}$ ions to the $^4I_{15/2}$ energy level of Nd$^{3+}$ ions followed by radiative transfer to the low lying $^4F_{7/2}$ level of Nd$^{3+}$ ions. Subsequently, energy transfer from $^4F_{7/2}$ to $^4F_{3/2}$ occurs nonradiatively. Radiative relaxation from $^4F_{3/2}$ levels to the $^4I_{11/2}$ and $^4I_{13/2}$ energy levels of Nd$^{3+}$ ions, lead to the 1064 nm and 1339 nm NIR emissions, respectively. Similarly, for Sm$^{3+}$-doped CeF$_3$ nanocrystals, upon 280 nm excitation, Ce$^{3+}$ ions are excited from the 4f$^1$ level. A radiative energy transfer occurs from the lowest 4f$^5$d level of Ce$^{3+}$ ions to the $^4D_{3/2}$ energy level of Sm$^{3+}$ ions followed by nonradiative transfer to the low lying $^4G_{5/2}$ level of Sm$^{3+}$ ions. Subsequent decays from $^4G_{5/2}$ levels and $^6F_{5/2}$, $^6F_{7/2}$ and $^6F_{9/2}$ levels result in emissions in the visible and NIR regions.

![Energy transfer mechanism diagram](image-url)
4. Conclusions

In conclusion, we have successfully synthesized hexagonal phase Ln$^{3+}$ doped CeF$_3$ nanocrystals via a microwave assisted method. The morphology of the nanocrystals was oval shaped with an average aspect ratio of ~0.8. The nanocrystals are functionalized with citrate molecules which render them highly water dispersible. In Nd$^{3+}$ and Sm$^{3+}$-doped CeF$_3$ nanocrystals, enhanced visible and near infrared (NIR) emissions were observed via Ce$^{3+}$ ion sensitization upon ultraviolet (UV) irradiation ($\lambda_{\text{exi}} = 280$ nm). The energy transfer mechanism from Ce$^{3+}$ to Nd$^{3+}$ and Sm$^{3+}$ ions is proposed. The strong NIR emissions from water dispersible nanocrystals are advantageous for bioimaging applications. In addition, they can easily be incorporated into polymers and other sol-gel matrices for the fabrication of devices for telecommunications.
