# Liquid crystalline dihydroazulene photoswitches†

Anne Ugleholdt Petersen,<sup>a</sup> Martyn Jevric,<sup>a</sup> Richard J. Mandle,<sup>b</sup> Edward J. Davis,<sup>b</sup> Stephen J. Cowling,<sup>b</sup> John W. Goodby<sup>b</sup> and Mogens Brøndsted Nielsen\*<sup>a</sup>

A large selection of photochromic dihydroazulene (DHA) molecules incorporating various substituents at position 2 of the DHA core was prepared and investigated for their ability to form liquid crystalline phases. Incorporation of an octyloxy-substituted biphenyl substituent resulted in nematic phase behavior and it was possible to convert one such compound partly into its vinylheptafulvene (VHF) isomer upon irradiation with light when in the liquid crystalline phase. This conversion resulted in an increase in the molecular alignment of the phase. In time, the meta-stable VHF returns to the DHA where the alignment is maintained. The systematic structural variation has revealed that a biaryl spacer between the DHA and the alkyl chain is needed for liquid crystallinity and that the one aromatic ring in the spacer cannot be substituted by a triazole. This work presents an important step towards employing the dihydroazulene-vinylheptafulvene photo/thermoswitch in photoactive liquid crystalline materials.

### Introduction

In the field of liquid crystals, it has been a goal to control the phases and order with an external stimulus. Some of the stimuli which have been applied include temperature, magnetic field, electric field and light. Light is an interesting stimulus, since this gives the possibility for remote control. Indeed, it has found use in image storing devices. Specifically, this has been shown with azobenzene polymer matrix, where an image was stored for 8 months without significant decay. Other photochromic molecules such as dithienylethenes, spiropyrans and fulgides have also shown suitable properties for this kind of application. Here we present a study on liquid crystalline systems based upon the dihydroazulene (DHA) photoswitch (Scheme 1). When irradiated with light, DHA 1 undergoes a ring-opening to the vinylheptafulvene (VHF) 2, which can then close back to the initial DHA *via* a thermal electrocyclization reaction.

The main advantage of the DHA-VHF photoswitch system is that only the DHA to VHF conversion is light-induced, which

Scheme 1 DHA 1/VHF 2 system.

means that a broad spectrum of light can be used without triggering the VHF to DHA back-reaction. The DHA ring-opening is associated with significant changes in the physical properties of the corresponding VHF. Thus, ring-opening is associated with an increase in dipole moment and a change in color from yellow (DHA) to intense red (VHF). See We became interested to elucidate if this difference in properties could give rise to reversible, photochemically induced phase transitions.

Molecules with liquid crystalline properties can have differing constructions, but for the purpose of this work, attention was given to rod-like structures. Typically, rod-like, liquid crystalline structures have two aliphatic chains extending from a rigid 'core' unit such as biphenyl or one alkyl chain with an additional terminal substituent such as a nitrile.10 It was decided to incorporate either a cyanophenyl-substituted alkyl in the one end of DHA or an octyl chain. In the literature there are many examples of the cyanobiphenyl being used as the terminal substituent,11 but as this unit has absorption properties which conflict with the wavelength needed for the ringopening event of DHA, the cyanophenyl substituent was used predominantly in this study, as in structures 3a-e and 4a-e (Fig. 1). Structures 3f-i and 4j instead have an octyl end-group. Both cyanophenyl and octyl groups have been used previously to achieve liquid crystallinity.12

## 2. Results and discussion

#### 2.1 Synthesis

The most convenient method for the construction of 2-substituted DHAs originates from derivatized acetophenones. Several strategies were undertaken in the pursuit of obtaining the starting acetophenones (Scheme 2). From the simple precursors 5a-e, 6, 7a-e, 8, acetophenones 9a-e were prepared

in two successive reactions. Thus, dibromoalkanes 5a-e of various chain lengths were treated with phenols 6 and 8. Conversely, acetophenones containing biaryl units, 9f and 9g, were obtained in good yields from a palladium-catalyzed Suzuki cross-coupling reaction from 4-iodoacetophenone 10 with boronic acids 11f and 11g, respectively, using conditions that proved fruitful in the synthesis of the benzaldehyde analogues.13 Finally, 9h could be formed in high yield by a Friedel-Crafts reaction of 12 with acetyl chloride using a literature procedure.14 Compound 9i was purchased.

Acetophenones 9a-i could be transformed successfully into the corresponding DHAs 3a-i (Scheme 3) by firstly converting the carbonyl moiety into a crotononitrile unit in a Knoevenagel condensation furnishing intermediates 13a-i, generally in good yields. Intermediates 13a-i were then treated with tropylium tetrafluoroborate in the presence of triethylamine to affix the cycloheptatriene unit to the malonitriles which could be further converted into 3a-i by subsequent oxidation using tritylium tetrafluoroborate followed by treatment with triethylamine. Alternatively, biaryl DHAs 3f and 3g could be obtained directly from DHA 15 in a Suzuki reaction with boronic acids 11f and 11g, using the catalytic system of palladium acetate and RuPhos (Scheme 4). A separate strategy involving the introduction of the extended chains could also be effected using the coppercatalyzed azide-alkyne cycloaddition (CuAAC)15 to form triazole compounds. Triazoles have previously been incorporated successfully into liquid crystalline compounds<sup>16</sup> and, synthetically, DHA has been found to withstand the conditions.<sup>17</sup> Alkyl bromides 7a-e were converted into their corresponding azides 14a-e (Scheme 5) and when subjected to treatment with 10 mol% cuprous iodide in the presence of 16 and Hünig's base, triazoles 4a-e were achieved. DHA 4j could be made from a CuAAC of octyl azide with 16 in the same manner.

We also decided to prepare the corresponding VHFs of two of the DHAs (to study their liquid crystalline properties of relevance for the switching studies, vide infra). It has been shown that DHA can be ring-opened by treatment with AlCl<sub>3</sub> to afford the corresponding VHF18 and this method could be used to convert 3f into 17 in good yield (Scheme 6). When the method was used on 3g, not only did the DHA undergo ring-opening to

the VHF, but these reaction conditions also resulted in the cleavage of the octyl chain to form phenol 18.

#### 2.2 Photochemical properties

All DHAs made in this study show photoactive properties akin to that of unfunctionalized DHA 1. All DHAs exhibited an absorption maximum at around 360 nm and when irradiated with light of this wavelength, they undergo an electrocyclic ringopening reaction. Thereby a peak at 475 nm emerges, corresponding to the formation of the VHF (Table 1). The rate of VHF to DHA thermal ring-closure has been found to be influenced greatly by the introduction of electron-donating/accepting functional groups. 9,19 The VHFs of DHAs 3a-e all exhibit a rate constant corresponding to that of the p-methoxy substituted derivative of DHA 1. The rate of ring-closure for the VHFs of the triazole derivatives 4a-e and 4j show a small deviation from

a formerly reported triazole functionalized DHA,17 which had a rate constant for the VHF ring-closure of  $7.45 \times 10^{-5}$  s<sup>-1</sup>. The VHFs of 3h and 3i have comparable ring-closure rate constants as those of the VHFs of 3a-e and of formerly reported DHA with a p-methyl substituent. Inclusion of fluorine seems to have no effect for the VHF of 3h, or its effect is cancelled by the electrondonating octyloxy substituent. For the biphenyls 3f and 3g the rate of VHF to DHA conversion is higher and more similar to that of 4a-e. Here the effect of the fluorine is clear; the rate increases to  $7.30 \times 10^{-5} \text{ s}^{-1}$  compared to the non-fluorinated compound with a rate of  $6.78 \times 10^{-5} \text{ s}^{-1}$ .

#### Physical properties

The synthesized molecules were examined by polarized optical microscopy (POM), but all starting materials en route to and including DHAs 3a-e from the first two approaches did not show any liquid-crystalline properties. The same could also be said for DHAs 4a-e and 4j. Instead, biaryl containing acetophenones 9f and 9g and the corresponding DHAs 3f and 3g exhibited a liquid-crystalline phase and were examined by both POM and differential scanning calorimetry (DSC). Compound 9f was found to exhibit a mesophase. Indeed, 9f (Fig. 2) has been previously reported with two different transitions, where in one, it exhibited a smectic E phase,20 and in the other, a melt was reported at 115-118 °C.21 We found that under the microscope 9f did exhibit a smectic phase (see Fig. 2), in agreement with the former report although definitive phase assignment was not possible due to the short range of supercooling. Hence, we denote it smectic X. Fig. 3 shows the DSC thermogram.

DSC showed a transition for a mesophase, where the size of the associated enthalpy to the phase transition is indicative of the formation of a smectic mesophase. The partially fluorinated analogue 9g gave a lower melt and did not exhibit a liquidcrystalline phase during the heating process. Upon cooling, a peak corresponding to a liquid-crystalline phase could only be observed in the DSC at 53.8  $^{\circ}$ C. It was only possible to observe

Fig. 2 Photomicrographs of the smectic X phase of 9f at 118 °C.

Fig. 3 (Top) DSC thermograms at a heating–cooling rate of 10  $^{\circ}$ C min<sup>-1</sup> for compound **9f**. (Bottom) DSC thermograms at a heating–cooling rate of 5  $^{\circ}$ C min<sup>-1</sup> for compound **9g**, where the dashed line is the first heating.

this phase when the sample had been heated to 100  $^{\circ}$ C prior to cooling. When compound 9g was heated to a lesser extent, such as 67 or 80  $^{\circ}$ C, the sample underwent crystallization during the cooling phase prior to the temperature where this initial phase transition was observed. When examined by POM, the crystallization occurred prior to the liquid crystal phase transition temperature. Table 2 lists transition temperatures for 9f and 9g and Table 3 the enthalpies and entropies associated with the transitions.

The two DHAs **3f** and **3g** showed liquid crystalline properties, whilst **3h** and **3i** did not exhibit any mesophases. This suggests that the additional aryl ring is important for the modified DHAs

to demonstrate liquid crystalline properties. Neither **3f** nor **3g** exhibited a mesophase in the first heating cycle, but upon cooling, a nematic phase appeared (Fig. 4). Further cooling did not result in crystallization, instead a glass transition occurred and when reheating the glass, the nematic phase reappeared and the transition from nematic to isotropic liquid could also

Fig. 4 DSC thermograms at a heating-cooling rate of 5 °C min $^{-1}$  for compound **3f** (Top) and compound **3g** (Bottom). The dashed line corresponds to the first heating.

be observed. DHA **3f** gave a melt at 90.6 °C and the nematic phase appeared upon cooling at 75.7 °C, see Fig. 4. On heating, the clearing point was found to be at 75.6 °C. The phase transitions showed small enthalpy changes, which agrees with the changes from nematic to liquid phase and *vice versa*. For the fluorinated **3g** analogue, the melt occurred at a temperature about 10 °C lower than for **3f**. The clearing point for the nematic phase of **3g** is 52.6 °C, while it is 75.7 °C for **3f**. Table 4 lists transition temperatures for **3f** and **3g** and Table 5 the enthalpies and entropies associated with the transitions.

When 3f is irradiated (at 365 nm) in the nematic phase, a color change from yellow-orange to red can be observed by the naked eye, but this did not correspond to a change in the phases. When solid VHF 17 was heated to 40 °C for 24 h, neither a change in color nor a phase change was observed, while heating the same material to 80 °C resulted in a simultaneous melt and color change to yellow ascribed to conversion to the DHA state. When 3g was irradiated with light in the nematic phase at 40 °C for 60 min, conversion to the corresponding VHF occurred in a ratio of 3:7 (VHF/DHA) as determined by NMR spectroscopy. After one hour of irradiation, using POM one could see an increase in the alignment of the nematic phase, such that the defects disappear (Fig. 5c). Irradiation for a prolonged period (16 hours) afforded no further changes in neither the POM picture nor in the isomer ratio determined by NMR spectroscopy. When left in the dark to reclose to form the DHA, the alignment is maintained. If the top glass slide is sheared horizontally to disrupt the alignment, the nematic texture appears for the DHA, (Fig. 5d). If the same disruption is done with the VHF present, the alignment reforms over several minutes. In addition to the VHF structure being planar, it also

	$\Delta S/R$	0.1671	10.80	0.1498

has a larger dipole moment, which could in essence lead to this larger degree of alignment of the total system relative to the corresponding neat nematic DHA. There are several examples in the literature<sup>22</sup> with photoalignment; the difference is that our experiment was performed in between untreated glass slides, which gives a texture. This texture then disappears upon irradiation. On the other hand, when heating pure VHF 17, no mesophases were observed for VHF 17, instead a rapid ring-closure to 3f occurred.

### 3. Conclusions

In order to ascertain the requirements of substitution needed to make the DHA photoswitch liquid crystalline, we have prepared a large selection of compounds with various substituents at position 2 of the DHA core. Of these compounds, two exhibited a nematic liquid crystal phase, both of which had an octyloxybiaryl attached to C2 of DHA. Irradiation of the one compound, with fluorine substitution of the biaryl, in its nematic phase partly formed the VHF. This DHA/VHF mixture exhibited a higher degree of alignment. In time, the DHA was regenerated and the order maintained. Nevertheless, full conversion to the VHF from the DHA in the nematic phase was not possible. This work presents an important step in using the DHA-VHF system in photoactive liquid crystalline materials. Future work will be aiming at exploring the influence of having two substituent groups on the DHA core.

# 4. Experimental

#### 4.1 General methods

Chemicals were used as purchased from commercial sources. Purification of products was carried out by flash chromatography on silica gel (40-63 μm, 60 Å). Thin-layer chromatography (TLC) was carried out using aluminum sheets precoated with silica gel. <sup>1</sup>H NMR (500 MHz) and <sup>13</sup>C NMR (125 MHz) spectra were recorded on an instrument with a noninverse cryoprobe using the residual solvent as the internal standard (CDCl<sub>3</sub>, <sup>1</sup>H 7.26 ppm and <sup>13</sup>C 77.16 ppm). All chemical shifts are quoted on the  $\delta$  scale (ppm), and all coupling constants (*J*) are expressed in Hz. In APT spectra, CH and CH3 correspond to negative signals and C and CH2 correspond to positive signals. High resolution mass spectra (HRMS) were acquired either using an electrospray method of ionization (ESP) or using MALDI. Melting points are uncorrected. Compounds 15 (ref. 23) and 16 (ref. 24) were made by their respective literature methods.

General procedure for 7a–e. A mixture consisting of 4-cyanophenol 6, the dibromide 5 (either a–e; 2–2.5 molar equivalents) and  $K_2CO_3$  (1.5–2 molar equivalents) in acetone (200 mL) was heated to reflux point for 16 h. The contents of the vessel were allowed to cool to rt and filtered. The solvent was removed from the filtrate and the crude residue was subjected to column chromatography (gradient elution of petroleum spirit to toluene) to afford 7 (either a–e) as a white solid.

General procedure for 13a-i. A biphasic mixture of 9 (either a-i), malononitrile (3.5-9 molar equivalents), NH<sub>4</sub>OAc (3-10 molar equivalents) in toluene (100-300 mL) and AcOH (4-23 mL) was heated using a Dean-Stark apparatus for 3-10 h. The vessel was cooled, diluted with toluene and decanted into a separatory funnel and water was added. The phases were separated and the organic phase washed with water and brine. The organic phase was dried over MgSO<sub>4</sub>, filtered and the solvent removed *in vacuo*. For subsequent purification for obtaining 13 (either a-i), see ESI.†

The reaction was quenched by addition of aqueous 1 M HCl (100 mL) and the vessel allowed to reach ambient temperature. The phases were separated and the organic phase dried over MgSO<sub>4</sub>, filtered and the solvent removed under reduced pressure. The residue was dissolved in CH2ClCH2Cl (50 mL) and to the vessel [Ph<sub>3</sub>C]BF<sub>4</sub> (851 mg, 2.58 mmol) was added whereafter the mixture was heated to reflux point for 2 h. The cooled vessel was placed in an ice bath and NEt<sub>3</sub> (0.70 mL, 5.0 mmol) was added slowly to the flask. Toluene (50 mL) was added to the flask and the contents allowed to sit overnight at rt, after which time the solvent was removed in vacuo and the crude residue purified by flash column chromatography (2% EtOAc/toluene) to give 3e (552 mg, 41%), as an orange solid.  $R_{\rm f} = 0.38$  (2% EtOAc/toluene). Mp = 102.2-121.8 °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta = 7.67$  (d, J = 8.9 Hz, 2H), 7.57 (d, J = 8.9 Hz, 2H), 6.97(d, J = 8.9 Hz, 2H), 6.93 (d, J = 8.9 Hz, 2H), 6.75 (s, 1H), 6.55 (dd, J)

2-(4'-(Octyloxy)-[1,1'-biphenyl]-4-yl)azulene-1,1(8aH)-dicarbonitrile (3f). Method 1: to a solution/suspension of the crude mixture from 13f (3.54 g, 9.50 mmol) and [C<sub>7</sub>H<sub>7</sub>]BF<sub>4</sub> (1.71 g, 9.61 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (250 mL), at -78 °C under an argon atmosphere, was added NEt<sub>3</sub> (1.0 g, 1.4 mL, 10 mmol) over a 30 min period and the reaction mixture stirred at -78 °C for 2 h. Additional NEt<sub>3</sub> was added (0.5 mL, 3.58 mmol) and the reaction mixture was left to stir for 1 h and allowed to reach rt and subjected to ultrasonication. HCl (150 mL, 2 M) was added to the vessel and the phases separated. The aqueous phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> (100 mL) and the combined organic phases dried over MgSO<sub>4</sub>, filtered, and the solvent was removed in vacuo. The residue was taken up in CH2ClCH2Cl (125 mL) and treated with [Ph<sub>3</sub>C]BF<sub>4</sub> (3.85 g, 11.6 mmol) and subjected to reflux for 2 h under inert atmosphere. The reaction mixture was diluted with toluene (125 mL) and cooled to 0 °C and NEt<sub>3</sub> (1.2 g, 1.7 mL, 12 mmol) was added, where the mixture was stirred overnight and allowed to reach room temperature. The solvent was removed in vacuum, and the residue was subjected to flash chromatography (40-50% CH2Cl2/heptane) and crystallized from CH<sub>2</sub>Cl<sub>2</sub>/ethanol to furnish 3f (502 mg, 11%) as a yellow solid. Method 2: To a degassed solution of 15 (1.54 g, 4.03 mmol) in toluene (60 mL) and water (15 mL) was added Pd(OAc)<sub>2</sub> (55 mg, 0.245 mmol), RuPhos (187 mg, 0.400 mmol), K<sub>3</sub>PO<sub>4</sub> (1.31 g, 6.17 mmol) and 11f (1.56 g, 6.24 mmol), and the biphasic mixture stirred for 18 h at 80 °C. TLC indicated an incomplete reaction and more Pd(OAc)<sub>2</sub> (60 mg, 0.267 mmol), RuPhos (195 mg, 0.419 mmol) and K<sub>3</sub>PO<sub>4</sub> (2.32 g, 10.9 mmol) and 11f (1.21 g, mmol) were added and the mixture heated to 80 °C for another 18 h. The contents of the vessel were diluted with water (100 mL) and the phases were separated. The aqueous phase was extracted with CH2Cl2 (100 mL) and the combined organic extracts were dried over MgSO4, filtered and the solvent removed in vacuo. The crude residue was subjected to flash column chromatography (gradient elution of 55-70% toluene/ heptane) and subsequently recrystallized from CH2Cl2/ heptane to give pure 3f (562 mg, 30%).  $R_f = 0.42$  (50% CH<sub>2</sub>Cl<sub>2</sub>/ heptane). 6.90, N 6.12. 2-(2',3'-Difluoro-4'-(octyloxy)-[1,1'-biphenyl]-4-yl)azulene-1,1(8aH)dicarbonitrile (3g). Method 1: to a mixture of 13g (3.35 g, 8.21 mmol) and  $[C_7H_7]BF_4$  (1.53 g, 8.60 mmol) in  $CH_2Cl_2$  (250 mL) at -78 °C under argon atmosphere was added NEt<sub>3</sub> (1.2 mL, 8.6 mmol) portion-wise over 30 min and the reaction mixture stirred at -78 °C for 2 h. Since there were still starting material and tropylium left unreacted, more NEt<sub>3</sub> was added (0.5 mL, 3.58 mmol) and the reaction mixture was left to stir for 1 h more and allowed to reach rt while being sonicated. Then it was quenched with HCl (100 mL, 2 M) and diluted with water (50 mL). Subsequently, the phases were separated and the water phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> (100 mL) and the combined organic phase was dried over MgSO4 and the solvent was removed by rotary evaporation. The residue was treated with [Ph<sub>3</sub>C]BF<sub>4</sub> (3.27 g, 9.89 mmol) in DCE (125 mL) under reflux for 2 h under an argon atmosphere, after which time the reaction mixture was cooled to 0 °C and diluted with toluene (125 mL). When the reaction mixture reached 0 °C, NEt<sub>3</sub> (1.5 mL, 10 mmol) was added, and the mixture was stirred overnight, while allowing to reach rt, and left to stir for 15 h. The solvent was removed in vacuo and the residue was subjected to flash column chromatography (40-50% CH<sub>2</sub>Cl<sub>2</sub>/heptane) and crystallized from CH<sub>2</sub>Cl<sub>2</sub> and ethanol to give 3g (1.104 g, 25%) as a yellow solid. Method 2: To a degassed solution of 15 (2.05 g, 5.36 mmol) in toluene (60 mL) and water (15 mL) were added Pd(OAc)<sub>2</sub> (76 mg, 0.339 mmol), RuPhos (262 mg, 0.561 mmol) and K<sub>3</sub>PO<sub>4</sub> (2.51 g, 11.8 mmol) and 11g (1.56 g, mmol). Degassed water (15 mL) was added and the biphasic mixture stirred for 18 h at 90 °C. Additional Pd(OAc)<sub>2</sub> (62 mg, 0.276 mmol), RuPhos (206 mg, 0.441 mmol) and  $K_3PO_4$  (1.80 g, 8.48 mmol) and 11g (1.04 g, mmol) were added and the mixture heated to 80  $^{\circ}\text{C}$  for a further 18 h. The contents of the vessel were diluted with water (100 mL) and the phases were separated. The aqueous phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> (100 mL) and the combined organic components were dried over MgSO<sub>4</sub>, filtered and the solvent removed in vacuo. The crude residue was subjected to flash column chromatography (20% EtOAc/heptane) and a second flash column (gradient eluent 40-60% CH<sub>2</sub>Cl<sub>2</sub>/heptane) and then recrystallized from CH<sub>2</sub>Cl<sub>2</sub>/ heptane to give 3g (522 mg, 20%).  $R_f = 0.44$  (50%  $CH_2Cl_2/heptane$ ). General procedure for 14a–e. To a solution of 7 (either a–e) in DMSO (20 mL), under an argon atmosphere, was added NaN<sub>3</sub> (1.5–2 molar equivalents) and the contents of the reaction vessel were heated to 50 °C for 2 h. The cooled reaction mixture was poured into ice-water (ca.50 g) and extracted with Et<sub>2</sub>O (3 × 75 mL). The combined organics were washed with water (100 mL), dried over MgSO<sub>4</sub>, filtered and the volatiles removed *in vacuo*. Purification by flash column chromatography (1% EtOAc/toluene) gave 14 (either a–e) as a white solid.

Mp = 126.1-130.6 °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta = 7.94$  (d, J = 8.4 Hz, 2H), 7.81 (s, 1H), 7.79 (d, J = 8.4 Hz, 2H), 6.93 (s, 1H), 6.57 (dd, J = 11.2, 6.3 Hz, 1H),6.48 (dd, J = 11.2, 6.1 Hz, 1H), 6.35 (d, J = 6.3 Hz, 1H), 6.34-6.28(m, 1H), 5.83 (dd, J = 10.2, 3.6 Hz, 1H), 4.41 (t, J = 7.2 Hz, 2H), $3.80 \, (ddd, J = 3.7, 1.9, 1.9 \, Hz, 1H), 1.99-1.91 \, (m, 2H), 1.97-1.95$ (m, 2H), 1.42–1.18 (m, 8H), 0.87 (t, J = 6.8 Hz, 3H) ppm. <sup>13</sup>C NMR (125 MHz, CDCl<sub>3</sub>):  $\delta = 146.6$ , 139.7, 138.7, 132.3, 130.9, 130.9, 129.9, 127.7, 126.7, 126.3, 121.1, 120.0, 119.5, 115.2, 112.7, 51.1, 50.6, 45.1, 31.7, 30.4, 29.1, 29.0, 26.5, 22.6, 14.1 ppm, 1C masked. HRMS (MALDI +ve) calcd for C<sub>28</sub>H<sub>30</sub>N<sub>5</sub> ([M + H]<sup>+</sup>): m/z = 436.2496; exp 436.2495. Analysis calcd (%) for C<sub>28</sub>H<sub>29</sub>N<sub>5</sub> (435.58): C 77.21, H 6.71, N 16.08; found: C 77.15, H 6.80, N 15.94.

2-(2-(Cyclohepta-2,4,6-trien-1-ylidene)-1-(4'-(octyloxy)-[1,1'biphenyl]-4-yl)ethylidene)malononitrile (17). To a stirred solution of 3f (418 mg, 0.908 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (50 mL) at rt under an argon atmosphere, was added AlCl<sub>3</sub> (341 mg, 2.56 mmol). After continued stirring for approximately 20 min, TLC analysis indicated the presence of unreacted 3f and more AlCl<sub>3</sub> (183 mg, 1.37 mmol) was added to the vessel and the reaction allowed to stir a further 20 min. The mixture was cooled on an ice bath and quenched by addition of ice-water (100 mL) and the phases separated. The aqueous phase was extracted with  $CH_2Cl_2$  (2 × 50 mL) and the combined organic phases dried over MgSO4 and filtered. The solution was diluted with heptane (100 mL) and the CH2Cl2 was removed by rotary evaporation while being kept at 0 °C. The solution was placed in a freezer resulting in the crystallization of 17, which was isolated as a dark red solid (368 mg, 88%). This material was stored in the freezer to prevent ring-closure back to 3f. Mp = 105-109 °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta = 7.35 \, (d, J = 8.2 \, Hz, 2H), 7.35 \, (d, J = 8.7 \, Hz, 2H), 7.10 \, (d, J)$ = 8.2 Hz, 2H, 6.91 (d, J = 8.7 Hz, 2H), 6.12 (s, 1H), 5.80 (dd, J)= 11.4, 1.5, 1H, 5.65 (dd, J = 12.2, 2.1 Hz, 1H), 5.59–5.49 (m, 2H), 5.46-5.42 (m, 1H), 5.10 (dd, J = 12.2, 7.8 Hz, 1H), 3.69 (t, J = 6.5 Hz, 2H, 1.68-1.63 (m, 2H), 1.39-1.34 (m, 2H), 1.33-1.18 (m, 8H), 0.92 (t, J = 7.0 Hz, 3H) ppm. <sup>13</sup>C NMR (125 MHz,  $CDCl_3$ ):  $\delta = 167.8, 160.1, 152.9, 143.7, 142.2, 135.2, 134.7,$ 

134.2, 133.3, 133.2, 132.7, 132.1, 129.3, 128.6, 128.4, 127.6, 119.8, 115.3, 78.4, 68.1, 32.2, 29.8, 29.7, 29.7, 26.4, 23.1, 14.4 ppm, 1C masked. HRMS (MALDI +ve) calcd for  $C_{32}H_{32}N_2ONa$  [(M + Na)<sup>+</sup>]: m/z = 483.2407, found m/z = 483.2412. Analysis calcd (%) for  $C_{32}H_{32}N_2O$  (496.62): C 83.49, H 7.00, N 6.08; found: C 83.38, H 7.11, N 6.14.

2-(2-(Cyclohepta-2,4,6-trien-1-ylidene)-1-(2',3'-difluoro-4'-hydroxy-[1,1'-biphenyl]-4-yl)ethylidene)malononitrile (18). To a stirred solution of 3g (210 mg, 0.423 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (50 mL) at rt, under an argon atmosphere, was added AlCl<sub>3</sub> (1.010 g, 7.58 mmol) and the mixture was stirred for 20 min. TLC analysis indicated the presence of unreacted 3g and more AlCl<sub>3</sub> (540 mg, 4.05 mmol) was added, whereby the reaction was allowed to stir a further 20 min. The mixture was cooled on an ice bath and quenched by addition of ice-water (100 mL) after which the phases were separated. The aqueous phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 50 mL) and the combined organic phases was dried with MgSO<sub>4</sub> and filtered. Heptane was added (100 mL), and the solution concentrated under reduced pressure at 0  $^{\circ}$ C, whereby the solution was placed at -18°C for 16 h, resulting in the crystallization of 18 (85 mg, 52%) as a dark red solid. This material was stored in the freezer to prevent ring-closure back to 3g. Mp = 129.7–131.0 (color change to yellow), 168 (decomposes) °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta = 7.61$  (d, J =7.9 Hz, 2H), 7.47 (d, J = 7.9 Hz, 2H), 7.13 (td, J = 8.3, 2.2 Hz, 1H), 6.90-6.84 (m, 1H), 6.75-6.69 (m, 1H), 6.45-6.37 (m, 2H), 6.35 (s, 1H), 6.33-6.27 (m, 1H), 5.94 (d, I = 4.6 Hz, 1H), 5.60 (br s, 1H, exchanges  $D_2O$ ) ppm. <sup>13</sup>C NMR (125 MHz, CDCl<sub>3</sub>):  $\delta = ppm$  <sup>13</sup>C NMR (125 MHz, CDCl<sub>3</sub>):  $\delta = 168.4$ , 154.1, 148.4 (dd, J = 250.4, 11.4 Hz), 145.0 (dd, J = 11.3, 2.0 Hz), 142.3, 137.7 (dd, J = 2.5, 1.6 Hz), 135.6, 135.3, 135.2, 134.5, 134.1, 133.7, 129.9 (d, J = 3.3 Hz), 128.6, 124.3 (dd, J = 3.8, 3.8 Hz), 121.4 (d, J = 9.8 Hz), 118.9, 115.1, 114.6,112.6 (dd, J = 3.6, 1.0 Hz) ppm, 2Cs masked. HRMS (MALDI +ve) calcd for  $C_{32}H_{31}F_2N_2O[(M + H)^+]$ : m/z = 358.1147, found m/z =385.1142.

# Acknowledgements

The Danish Council for Independent Research | Technology and Production Sciences (#12-126668) and University of Copenhagen are acknowledged for financial support. Dr Theis Brock-Nannestad, University of Copenhagen, is thanked for helpful discussions.
