Diastereodivergent organocatalysis for the asymmetric synthesis of chiral annulated furans†

Charlie Verrierb and Paolo Melchiorre*ab

Disclosed herein is a stereoselective method for the synthesis of 2,3-furan fused carbocycles bearing adjacent quaternary and tertiary carbon stereocenters. The chemistry is based on an asymmetric addition of \( \beta \)-ketoesters to 2-(1-alkynyl)-2-alkene-1-ones catalysed by natural cinchona alkaloids followed by a silver-catalysed intramolecular cycloisomerisation. By exploiting the distinct catalysis modes of quinine, which can act either as a general base or, upon opportune modifications, as a phase transfer catalyst, a complete switch of the enforced sense of diastereinduction is achieved. The stereodivergent systems enable access to the full matrix of all possible stereoisomeric products.

Introduction

This research project was motivated by our interest in devising a direct and versatile strategy for stereoselectively assembling chiral annulated furans. As shown in Fig. 1, many biologically active compounds and natural products possess a furan system fused to rings of various sizes and adorned with multiple stereocenters. Despite significant advances in preparing racemic 2,3-furan-fused carbocycles, there are only a few catalytic strategies for their direct stereoselective synthesis.

Herein, we describe a straightforward synthetic strategy for accessing six- and seven-membered-ring furan derivatives bearing adjacent quaternary and tertiary carbon stereocentres in very high yields and stereoselectivities. The chemistry, which uses readily available substrates and catalysts, is based on a two-step sequential process whereby an organocatalytic asymmetric addition of \( \beta \)-ketoesters 2 to cyclic 2-(1-alkynyl)-2-alkene-1-ones 1 (ref. 5 and 6) is followed by a silver-catalysed intramolecular cycloisomerisation of the transient allenyl ketone* intermediate 3 (Scheme 1). Significantly, we have identified two distinct catalytic systems which infer complementary diastereoselectivities, thereby enabling access to the full complement of stereoisomers of the annulated products 4 and 5 at will.*

Results and discussion

Our initial explorations focused on the reaction between 2-phenylethynyl-2-cyclohexen-1-one 1a (ref. 9) and the cyclic

![Fig. 1](https://example.com/fig1.png) Naturally occurring chiral annulated furans.

ketoster 2a in DCM and in the presence of 5 mol% of a chiral tertiary amine, which could act as a general base catalyst (deprotonative activation of 2a). The process was conducted in two sequential steps, with the initial organocatalytic path exclusively providing the corresponding allenyl ketone of type 3 (ref. 10) (Scheme 1) by means of a selective 4,5'-addition. Upon filtering out the chiral amine through SiO2 and evaporation of the solvent, the cycloisomerisation of crude 3a was achieved by applying a slightly modified Marshall procedure21 (using 10 mol% AgNO3 and AcOEt at 40 ºC) to afford the diastereomeric adducts 4 and 5.

We focused on identifying chiral organocatalysts that could infer high stereocontrol in the initial 4,5'-addition reaction. Representative results of our extensive studies are listed in Table 1, with more details reported in the ESI.† Intriguingly, natural cinchona alkaloid derivatives,12 acting as general base catalysts,13 afforded impressive levels of stereoselectivity (4a formed with a dr of up to 19 : 1, and an ee of up to 99%, entries 1–4), largely outperforming any other synthetic catalyst tested (see ESI†).

Importantly, the use of the “pseudoeantiomeric” catalysts quinine (QN) and quindine (QD) secured access to both enantiomers of the adduct 4 with excellent selectivity (entries 5 & 3, respectively). Protection of the quinine hydroxyl moiety resulted in a greatly reduced reactivity along with a complete loss of stereocontrol (entry 6). Mechanistically, this suggests that the cinchona catalysts might operate through a bifunctional activation mode, simultaneously binding and activating the two reacting partners.13e,14 Interestingly, the cupreidene derivative QN-OH, a catalyst with a proven ability to promote the highly stereoselective addition of β-ketosteres to cyclic enones, remained completely inactive in our system (entry 7).15

We then modified the cinchona alkaloid scaffold by alkylating the basic bridgehead nitrogen of the quinuclidine core, the classical approach for achieving catalysts suitable for use as phase transfer catalysts (PTCs).16 Among the many PTCs tested in the model reaction (see ESI† for details), the cinchona-derived trimeric species PTC-QN and PTC-QD,17 easily obtained by the poly-alkylation of quinine and quindine with 1,3,5-tris(bromomethyl)benzene, provided the most interesting results. When performing the reaction in DCM and in the presence of 33% K2CO3 aq., a complete switch of the enforced diastereoinduction was achieved, so that the adduct 5 was almost exclusively formed in high optical purity (entries 8 & 9).

These findings allowed us to fully control the stereochemical outcome of the process, enabling the generation of any stereoisomer of the annulated furans 4 and 5 at will. This is considered a challenging goal because when asymmetric catalysis is applied to processes that generate two stereogenic centres in one product, there is generally no obvious means of modifying a catalyst to modulate the relative sense of those two centres.8 In this case, the two diastereodivergent systems are based on different organocatalysts, but are derived from the common chiral core of natural cinchona alkaloids. The divergent stereocontrol arises from the ability of the cinchona catalysts to execute distinct modes of catalysis for activating the reagents (base catalysis vs. phase transfer catalysis, Scheme 2).

Having identified two distinct catalytic systems that can selectively channel the reaction manifold toward complementarily diastereochemical outcomes, we examined the scope of the two-step process using QN (5 mol%) as a general base catalyst. As revealed in Table 2, the method shows a wide substrate generality and an excellent level of stereoselectivity, providing access to a variety of complex annulated furans 4 adorned with two vicinal quaternary and tertiary stereocentres. We first tested the possibility of modifying the cyclic scaffold of the 2-(1-alkynyl)-2-alken-1-one component 1. The cycloheptenone derivative reacted smoothly to provide the seven-membered-ring furan 4b in high optical purity (entry 2). In contrast, the cyclooctenenone derivative was not a suitable substrate, since a complete lack of reactivity in the silver-catalysed intramolecular cycloisomerisation step was observed. Different substitution patterns on the aromatic moiety of 1 were well-tolerated, regardless of their electronic properties (entries

3–5). In addition, an alkyne bearing a vinyl substituent (entry 6) provided the corresponding furan 4f with high stereoselectivity, albeit with a moderate chemical yield. A limitation of the system is that we have thus far failed to react alkynes bearing alkyl or TMS groups, and linear substrates.

As for the nucleophilic partners 2, electronic variations in the indanone ring were possible, as both electron donating and withdrawing substituents gave the desired products in high yields and excellent diastereoselection (entries 7–11). Efforts to react six-membered cyclic and linear β-ketoesters need further optimization, since only traces of the corresponding products could be obtained.

We then evaluated the synthetic potential of the PTC-mediated system. As depicted in Table 3, the reactions catalysed by 5 mol% of PTC-QD showed a comparable versatility to the system under general base catalysis, but secured a complementary diastereoselectivity, since the opposite diastereoisomers 5 of

Conclusions

In conclusion, we have developed an operationally simple, two-step process to access a variety of stereochemically dense 2,3-furan fused carbocycles bearing adjacent quaternary19 and tertiary stereocentres. The salient feature of our study is that complementary organocatalytic systems, both using natural cinchona-derived catalysts, have been identified, which ensure highly selective access to the full matrix of all possible stereoisomic products at will.
