# The boron–boron triple bond in $\text{NHC} \rightarrow \text{B} \equiv \text{B} \leftarrow \text{NHC}^\ddagger$

Nicole Holzmann,<sup>a</sup> Markus Hermann<sup>a</sup> and Gernot Frenking<sup>\*ab</sup>

Quantum chemical calculations of the compound  $\text{B}_2(\text{NHC}^{\text{Me}})_2$  and a thorough examination of the electronic structure with an energy decomposition analysis provide strong evidence for the appearance of boron–boron triple bond character. This holds for the model compound and for the isolated diboryne  $\text{B}_2(\text{NHC}^{\text{R}})_2$  of Braunschweig which has an even slightly shorter B–B bond. The bonding situation in the molecule is best described in terms of  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  donor–acceptor interactions and concomitant  $\pi$ -backdonation  $\text{NHC}^{\text{Me}} \leftarrow \text{B}_2 \rightarrow \text{NHC}^{\text{Me}}$  which weakens the B–B bond, but the essential features of a triple bond are preserved. An appropriate formula which depicts both interactions is the sketch  $\text{NHC}^{\text{Me}} \rightleftharpoons \text{B} \equiv \text{B} \rightleftharpoons \text{NHC}^{\text{Me}}$ . Calculations of the stretching force constants  $F_{\text{BB}}$  which take molecules that have genuine single, double and triple bonds as references suggest that the effective bond order of  $\text{B}_2(\text{NHC}^{\text{Me}})_2$  has the value of 2.34. The suggestion by Köppe and Schnöckel that the strength of the boron–boron bond in  $\text{B}_2(\text{NHC}^{\text{H}})_2$  is only between a single and a double bond is repudiated. It misleadingly takes the force constant  $F_{\text{BB}}$  of OBBO as the reference value for a B–B single bond which ignores  $\pi$  bonding contributions. The alleged similarity between the B–O bonds in OBBO and the B–C bonds in  $\text{B}_2(\text{NHC}^{\text{Me}})_2$  is a mistaken application of the principle of isolable relationship.

## Introduction

In 2012, Braunschweig and co-workers reported the synthesis of the diboryne compound  $\text{B}_2(\text{NHC}^{\text{R}})_2$  where diatomic  $\text{B}_2$  binds two N-heterocyclic carbenes (NHC) which carry bulky groups R at nitrogen.<sup>1</sup> The X-ray structure analysis revealed a linear arrangement of the  $\text{NHC}^{\text{R}}$  ligands to the central  $\text{B}_2$  moiety and a very short B–B bond of 1.45 Å which agrees with the standard value for a triple bond (1.46 Å).<sup>2</sup> An earlier theoretical study that was published in 2011 had predicted that the molecule has very strong bonds which can be interpreted in terms of donor–acceptor interactions  $\text{NHC}^{\text{R}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{R}}$  where diatomic  $\text{B}_2$  is in the highly excited  $(3) ^1\Sigma_g^+$  singlet state rather than in the  $X ^3\Sigma_g^-$  ground state (Fig. 1a and b).<sup>3</sup>

Charge donation from the ligands takes place into the empty  $1\sigma_u$  MO (out-of-phase +,– donation) and the  $2\sigma_g$  MO (in-phase +, + donation) which is schematically shown in Fig. 1c. In addition to the  $\sigma$ -donation  $\text{NHC}^{\text{R}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{R}}$ ,  $\pi$ -backdonation  $\text{NHC}^{\text{R}} \leftarrow \text{B}_2 \rightarrow \text{NHC}^{\text{R}}$  may occur from the occupied  $1\pi_u$

and  $1\pi_u'$  orbitals which would weaken the  $\text{B} \equiv \text{B}$  triple bond. An energy decomposition analysis was carried out in 2013 which suggests that 2/3 of the total orbital interactions comes from  $\text{NHC}^{\text{R}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{R}}$   $\sigma$ -donation and 1/3 comes from  $\text{NHC}^{\text{R}} \leftarrow \text{B}_2 \rightarrow \text{NHC}^{\text{R}}$   $\pi$ -backdonation.<sup>4</sup> Thus, the bond order for the B–B can be expected between 2 and 3 while the triple bond character is retained in the diboryne whose bonding situation is properly sketched with the formula  $\text{NHC}^{\text{R}} \rightleftharpoons \text{B} \equiv \text{B} \rightleftharpoons \text{NHC}^{\text{R}}$ .

Very recently, Köppe and Schnöckel (KS) published in this journal a reinterpretation of the boron–boron bond in  $\text{NHC}^{\text{R}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{R}}$  where they question the assignment of a triple bond.<sup>5</sup> Using thermodynamic arguments and a correlation of force constants, KS suggest that the strength of the boron–boron bond in  $\text{NHC} \rightarrow \text{B}_2 \leftarrow \text{NHC}$  is only between a single and a double bond and that the molecule should better become described with traditional resonance structures. The conclusion of KS was made on the basis of selected experimental and calculated results. The authors write that their results ‘...generates a new interpretation which is in contrast to the triple bond donor–acceptor description visualized by arrows and which casts a critical light on the interpretation of any NHC “stabilized” molecule’. The statement was made without reference to the previous quantum chemical studies of  $\text{B}_2(\text{NHC}^{\text{R}})_2$ <sup>3,4,6</sup> nor to any other theoretical work about NHC stabilized molecules.<sup>7</sup>

We studied the paper by KS<sup>5</sup> very carefully and noticed several flaws in their arguments which cast severe doubts on their conclusions. In the following we critically discuss the approach and the conclusions of the authors. Our counter

arguments are presented in the same order as in the paper by KS.

## Thermodynamic view

KS begin their discussion with a lengthy description of the energy which is required for the formation of  $B_2$  in the excited  $(3)\ ^1\Sigma_g^+$  state (which is denoted as  $B_2^*$  in their paper) from solid boron in a gas-phase reaction which is irrelevant for the discussion of the bonding situation and for the formation and stability of the compound. The compound  $NHC^R \rightarrow B_2 \leftarrow NHC^R$  was prepared by Braunschweig by reacting  $NHC^R \rightarrow (B_2Br_4) \leftarrow NHC^R$  with sodium naphthalenide in THF solution which gives the product molecule *via* debromination reaction.<sup>1</sup> It is well known that molecules which have a large positive heat of formation can be isolated as stable compounds in straightforward reactions if the electronic structure is favourable.<sup>8</sup> KS arrive at the conclusion: “Therefore, nobody would conclude that  $B_2^*$  is stabilized in solid boron!”. But nobody ever claimed that solid boron would do that! What has been claimed is the significant stabilization of  $B_2^*$  through strong donor–acceptor interactions with NHC ligands.<sup>3,4,6</sup>

KS make the statement that the arrows in the formula  $NHC \rightarrow B_2 \leftarrow NHC$  “suggest only a weak donor (NHC)–acceptor ( $B_2^*$ ) interaction in which the bonding of the educt is still visible”.

But it was already shown in 2013<sup>3</sup> that the donor–acceptor interactions  $NHC \rightarrow B_2 \leftarrow NHC$  are very strong, which should be expected in light of the low-lying vacant orbitals of  $B_2^*$  (Fig. 1). The strong interactions do not lead to major changes in the structures of the donor and acceptor species which is easy to understand. The two vacant  $\sigma$  orbitals in  $B_2^*$  are bonding and antibonding, respectively, which roughly cancel the impact of the donor–acceptor interactions on the B–B bond length. The slightly longer B–B distance in  $NHC^R \rightarrow B_2 \leftarrow NHC^R$  (1.45 Å) than in free  $B_2^*$  (1.40 Å) is caused by  $\pi$ -backdonation from  $B_2$  to the NHC ligands. The geometry changes of the NHC ligands in  $NHC^R \rightarrow B_2 \leftarrow NHC^R$  are likewise rather small, because they involve mainly the carbene lone-pair orbital. Thus, the structure and stability of  $NHC \rightarrow B_2 \leftarrow NHC$  are in full accord with the bonding situation of a  $B \equiv B$  moiety which is stabilized by strong  $\sigma$ -donation of and  $\pi$ -backdonation to the NHC ligands.

## Determination and discussion of the force constants in $NHC \rightarrow B_2 \leftarrow NHC$

The main argument in the paper by KS against a triple bond character in  $NHC^R \rightarrow B_2 \leftarrow NHC^R$  rests on the force constants of the B–B stretching mode. The authors first discuss several molecules which may be used as reference for a B–B single bond. They choose OBBO as candidate, because it would “have a BB bonding situation similar to **1** with a linear  $X-B-B-X$  moiety” where **1** stands for  $NHC^R \rightarrow B_2 \leftarrow NHC^R$ . In order to underpin the connection between OBBO and **1** the authors refer to the isolobal relationship  $O \leftarrow \overline{O} \rightarrow CH_2$ . Then they write that “the Lewis formula  $O=B-B=O$  is in accordance with the values of the BB and BC force constants”.

There are two major flaws in the above arguments. One flaw concerns the suggestion that the boron–boron bond in OBBO is a single bond.<sup>9</sup> There are two orthogonal  $\pi$  components in the BO moieties which conjugate over the BB fragment. Using OBBO as template for a B–B single bond ignores the contribution of B–B  $\pi$ -bonding. Note that the authors suggest a Lewis structure  $O=B-B=O$  for the molecule which has an electron sextet at boron. The second flaw is the suggestion that the isolobal relationship  $O \leftarrow \overline{O} \rightarrow CH_2$  may be used to indicate a similar bonding situation in OBBO and  $NHC^R \rightarrow BB \leftarrow NHC^R$ .  $CH_2$  has an electronic ( ${}^3B_1$ ) triplet ground state which is 9.0 kcal mol<sup>−1</sup> below the ( ${}^1A_1$ ) singlet state.<sup>10</sup> Methylene is isolobal with oxygen atom, because both species have a triplet state and a similar shape and energy.<sup>11</sup> In contrast, NHC has a singlet ground state which is 85 kcal mol<sup>−1</sup> below the triplet state.<sup>12</sup> It means that the electronic structure and the chemical reactivity of the carbene carbon atom of NHC are very different from  $CH_2$ , which is common knowledge in chemistry.<sup>13</sup> A pertinent example which demonstrates the large difference between the two carbenes is given by the compounds where they bind to a single carbon atom.  $C(CH_2)_2$  is the parent allene  $H_2C=C=CH_2$  which has a linear structure with  $C=C$  double bonds and perpendicular  $CH_2$  planes.  $C(NHC)_2$  is a carbene  $CL_2$  which features two donor–acceptor bonds  $L \rightarrow C \leftarrow L$  to a carbon atom which retains two electron lone pairs.<sup>14</sup> The carbodicarbene  $C(NHC^{Me})_2$  has a

bond angle  $(\text{NHC}^{\text{Me}})_2\text{C}-(\text{NHC}^{\text{Me}})_2$  of  $132^\circ$ <sup>15</sup> which is similar to the isolobal carbodiphosphorane  $\text{C}(\text{PPh}_3)_2$  which has a bond angle of  $135^\circ$ .<sup>16</sup> The first carbodicarbenes  $\text{C}(\text{NHC}^{\text{R}})_2$  were recently synthesized by Bertrand and by Fürstner.<sup>17</sup> It is obvious that the isolobal relationship  $\text{O}=\text{C}=\text{CH}_2$  does not hold for NHC.

We searched for a molecule which possesses a genuine B–B single bond. The vast experimental information which has been accumulated about boron compounds clearly shows that boron atoms in stable molecules have at least partially filled four valence AOs which makes the search for an experimental value of species with a B–B single bond futile. We therefore looked for a model compound with a genuine B–B single bond that can be calculated with an accuracy that rivals experimental values. A suitable species is planar  $\text{H}_2\text{B}-\text{BH}_2$  where the  $p(\pi)$  orbitals of boron are vacant. The planar ( $D_{2h}$ ) structure is a transition state for the rotation about the B–B bond of  $\text{B}_2\text{H}_4$  which has a perpendicular ( $D_{2d}$ ) equilibrium structure. The B–B bond in the  $D_{2d}$  energy minimum structure has been calculated to be much shorter (1.623 Å) than in the planar form (1.752 Å) which is due to significant hyperconjugation that was estimated from the energy difference between the  $D_{2d}$  and  $D_{2h}$  structures (17.3 kcal mol<sup>−1</sup>).<sup>18</sup> The reported B–B bond length of 1.65 Å for OBBO which is much shorter than the single bond in planar  $\text{B}_2\text{H}_4$  (1.752 Å) indicates a substantial degree of B–B  $\pi$ -bonding which makes the molecule unsuitable as reference for a single bond.

We calculated the force constant for the B–B stretching mode in planar  $\text{H}_2\text{B}-\text{BH}_2$  and took the value of  $F_{\text{BB}} = 2.49$  mdyn Å<sup>−1</sup> as reference value for a B–B single bond. A related molecule with a genuine B=B double bond is HBBH in the ( $^3\Sigma_g^-$ ) triplet state which has a B–B  $\sigma$  bond and two singly occupied B–B  $\pi$  orbitals. The calculated force constant for the B–B stretching mode is  $F_{\text{BB}} = 5.38$  mdyn Å<sup>−1</sup> which is taken as reference value for a B=B double bond. The reference value for a B≡B triple bond comes from the calculated force constant for the ( $^3\Sigma_g^+$ ) state of  $\text{B}_2$  which has the value of  $F_{\text{BB}} = 7.62$  mdyn Å<sup>−1</sup>. The B–B force constants in mdyn Å<sup>−1</sup> of the hydroboranes for a single bond (2.49; planar  $\text{B}_2\text{H}_4$ ), double bond (5.38, triplet  $\text{B}_2\text{H}_2$ ) and triple bond (7.62; ( $^3\Sigma_g^+$ )  $\text{B}_2$ ) exhibit the same ratio 1 : 2 : 3 as the force constants  $F_{\text{CC}}$  for the C–C bonds in the analogous hydrocarbons which were given by KS as 4.4 ( $\text{C}_2\text{H}_6$ ), 9.1 ( $\text{C}_2\text{H}_4$ ) and 15.6 ( $\text{C}_2\text{H}_2$ ).<sup>5</sup> The regular increase of the force constant is at first sight a bit surprising, since the additional components of the multiple bonds are  $\pi$  bonds which are weaker than  $\sigma$  bonds. Along with the addition of  $\pi$  bonding, there is a concomitant change in the hybridisation of the  $\sigma$  bond which enhances the overall bonding and leads to the approximate relation 1 : 2 : 3.<sup>19</sup>

Fig. 2 shows a correlation diagram between the force constants and the bond orders of the reference compounds  $\text{H}_2\text{B}-\text{BH}_2$  (planar),  $\text{HB}=\text{BH}$  ( $^3\Sigma_g^-$ ) and  $\text{B}_2$  ( $^3\Sigma_g^+$ ) which exhibits a linear correlation coefficient of  $R^2 = 0.995$ . The calculated force constant  $F_{\text{BB}} = 3.5$  for OBBO suggests a bond order of 1.36, which indicates a significant contribution of  $\pi$  bonding. The force constant  $F_{\text{BB}} = 6.0$  which was calculated by KS for  $\text{NHC} \rightarrow \text{B}_2 \leftarrow \text{NHC}$  now indicates an effective bond order for the B–B bond of 2.34. This is in agreement with the classification as a molecule which has a B≡B triple bond that is

weakened by  $\pi$ -backdonation. The assignment of the much lower bond order of 1.5 for the complex which was suggested by KS is misleading, because it arbitrarily uses a bond order of 1.0 for OBBO, which neglects the  $\pi$  contribution to the B–B bond.

## Bonding analysis of $\text{NHC} \rightarrow \text{B}_2 \leftarrow \text{NHC}$

The above discussion provides information about the relative strength of the B–B bond in the complex  $\text{NHC}^{\text{R}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{R}}$  compared with reference compounds which were chosen by KS (OBBO) and by us (planar  $\text{H}_2\text{B}-\text{BH}_2$ , triplet HBBH and ( $^3\Sigma_g^+$ )  $\text{B}_2$ ) which, however, does not give insight into the nature of the bonding. Quantitative information is available from EDA-NOCV<sup>20</sup> (Energy Decomposition Analysis<sup>21</sup> combined with Natural Orbitals for Chemical Valence<sup>22</sup>) calculations. The advantage of the recently developed EDA-NOCV method over the EDA procedure which we used in our earlier bonding analysis<sup>4</sup> of  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  is, that the orbital interactions are broken down to a sum of pairwise contributions which provides detailed information about the strength of specific pairs of orbitals. The results give a complete picture of the bonding between the interacting fragments which can be connected with classical bonding models of chemistry. A helpful feature of the EDA-NOCV method is, that the results of the calculations can not only numerically be expressed but that the impact of the pairwise orbital interactions on the electronic structure can also graphically be visualized. Details of the calculations are given in ESI.† For further information about the EDA-NOCV method<sup>23</sup> and recent examples we refer to the literature.<sup>24</sup>

Table 1 gives the numerical data of the EDA-NOCV calculations of the complex  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  for the interactions between the acceptor ( $^3\Sigma_g^+$ )  $\text{B}_2$  (for the choice of the latter excited state of  $\text{B}_2$  see ref. 4) and the donor  $(\text{NHC}^{\text{Me}})_2$  at the geometry of the complex. The instantaneous interaction energy  $\Delta E_{\text{int}} = -307.5$  kcal mol<sup>−1</sup> is very large and overcompensates the electronic excitation energy of  $\text{B}_2$  of 106.4 kcal mol<sup>−1</sup>. The interaction energy  $\Delta E_{\text{int}}$  comprises the Pauli repulsion  $\Delta E_{\text{Pauli}}$  (259.0 kcal mol<sup>−1</sup>) and the binding interactions which comes from the Coulombic attraction  $\Delta E_{\text{elstat}}$  (−252.3 kcal mol<sup>−1</sup>) and

Fig. 2 Correlation between the force constants  $F_{\text{BB}}$  for boron–boron single, double and triple bonds (●) and the values for OBBO and  $\text{B}_2(\text{NHC}^{\text{Me}})_2$  (+).

**Table 1** Results of the EDA-NOCV calculations for  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  at BP86/TZ2P using the fragments  $\text{B}_2[(3) {}^1\Sigma_g^+]$  and  $(\text{NHC}^{\text{Me}})_2$  as interacting species. $\Delta E_{\sigma 2} \text{ L} \rightarrow (\text{B}_2) \leftarrow \text{L} (+, -)$ donation <sup>b</sup>	−86.9 (27.7%)
$\Delta E_{\pi 1} \text{ L} \leftarrow (\text{B}_2) \rightarrow \text{L} \pi$ -backdonation <sup>b</sup>	−48.0 (15.3%)
$\Delta E_{\pi 2} \text{ L} \leftarrow (\text{B}_2) \rightarrow \text{L} \pi'$ -backdonation <sup>b</sup>	−42.4 (13.5%)
$\Delta E_{\text{rest}}$	−24.2 (7.7%)
$q(\text{B}_2)$	−0.36

<sup>a</sup> The value in parenthesis gives the percentage contribution to the total attractive interactions  $\Delta E_{\text{elstat}} + \Delta E_{\text{orb}}$ . <sup>b</sup> The value in parenthesis gives the percentage contribution to the total orbital interactions  $\Delta E_{\text{orb}}$ .

the covalent (orbital) term  $\Delta E_{\text{orb}}$  (−314.2  $\text{kcal mol}^{-1}$ ). The EDA-NOCV calculations suggest that the donor-acceptor bonds  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  have a slightly more covalent (55.5%) character than electrostatic character (44.5%).

The breakdown of the orbital term  $\Delta E_{\text{orb}}$  into pairwise contributions between occupied and vacant MOs of the fragments provide quantitative insight into the  $\sigma$ -donation  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$  and  $\pi$ -backdonation  $\text{NHC}^{\text{Me}} \leftarrow \text{B}_2 \rightarrow \text{NHC}^{\text{Me}}$ . The associated charge flow can be visualized through the deformation densities  $\Delta\rho_1 - \Delta\rho_4$  that are shown in Fig. 3, left column. The colour code indicates the direction of the charge flow red  $\rightarrow$  blue. The occupied and vacant orbitals which are connected to the deformation densities are displayed in the three columns at the right side of Fig. 3. There are strongly stabilizing contributions from the in-phase (+,+)  $\text{NHC}^{\text{Me}} \rightarrow \text{B}_2 \leftarrow \text{NHC}^{\text{Me}}$   $\sigma$ -donation into the LUMO + 1 of  $(3) {}^1\Sigma_g^+ \text{B}_2$  ( $\Delta E_{\sigma 1} = -112.7 \text{ kcal mol}^{-1}$ ) while the out-of-phase (+,−) donation into the energetically lower-lying LUMO is a bit smaller ( $\Delta E_{\sigma 2} = -86.9 \text{ kcal mol}^{-1}$ ) which is due to the better overlap of the former (+,+) donation. There two contributions of the  $\text{NHC}^{\text{Me}} \leftarrow \text{B}_2 \rightarrow \text{NHC}^{\text{Me}}$   $\pi$ -backdonation are clearly smaller ( $\Delta E_{\pi 1} = -48.0 \text{ kcal mol}^{-1}$  and  $\Delta E_{\pi 2} = -42.4 \text{ kcal mol}^{-1}$ ) than the  $\sigma$ -donation. Since both components,  $\sigma$ -donation and  $\pi$ -backdonation significantly contribute to the bonding, a more appropriate notation for the bonding interactions is the formula  $\text{NHC}^{\text{Me}} \rightleftharpoons \text{B} \equiv \text{B} \rightleftharpoons \text{NHC}^{\text{Me}}$ . Since the  $\pi$ -backdonation weakens the boron-boron bond, a smaller bond order below 3 but above 2 is expected, which is in agreement with the effective bond order of 2.34 that was derived from the force constants.

The numerical results of the EDA-NOCV calculations and the graphical display of the deformation densities together with the molecular orbitals provide a bridge between heuristic bonding models of chemistry and a quantum chemical analysis of the electronic structure of the investigated complex. The calculated energy values are not observable data, but they arise from an unambiguously defined partitioning scheme which is not very

**Scheme 1** Bonding situation in  $\text{B}_2(\text{NHC})_2$  which were suggested (a) by Köppe and Schnöckel and (b) by us.

sensitive to the level of theory. The value of the EDA-NOCV method lies in the fact that it establishes a quantitative classification scheme where comparisons can be made with related compounds. Explanations for experimental findings and predictions for new compounds can be made for different ligands L and atoms E in complexes  $\text{L} \rightarrow \text{E}_2 \leftarrow \text{L}$  as well as for compounds  $\text{L} \rightarrow \text{E} \leftarrow \text{L}$  by considering the electronic states of  $\text{E}_2$  or E and the donor strength of L. This has been shown for numerous complexes of atoms E of group 13,<sup>3,4,6,25</sup> group 14<sup>14,15,26</sup> and group 15.<sup>8c,27</sup> The same approach has recently been used to predict stable beryllium compounds  $\text{L} \rightarrow \text{Be}_2 \leftarrow \text{L}$ .<sup>28</sup>

We would like to make a comment on the use of the different notations which were used by KS and by us for describing the bonding situation in  $\text{B}_2(\text{NHC}^{\text{R}})_2$  (see Scheme 1). The two formulas are not just different writing styles but they refer to different bonding situations between  $\text{B}_2$  and the  $\text{NHC}^{\text{R}}$  moieties. The notation with arrows  $\text{NHC}^{\text{Me}} \rightleftharpoons \text{B} \equiv \text{B} \rightleftharpoons \text{NHC}^{\text{Me}}$  indicates *heterolytic* cleavage of dative bonds while the notation with dashed lines as suggested by KS suggests conjugation over electron-sharing bonds which cleave *homolytically*. The latter description is appropriate for molecules such as 1,2-butadiene where rupture of the C–C bonds yields radicals. Cleavage of the B– $\text{NHC}^{\text{R}}$  bonds gives closed-shell fragments. Recognizing the difference between the two types of bonding has led to the discovery of carbones  $\text{CL}_2$  as a peculiar class of organic compounds and related systems which exhibit unusual geometries and reactivities and to the prediction of novel compounds.<sup>29</sup>

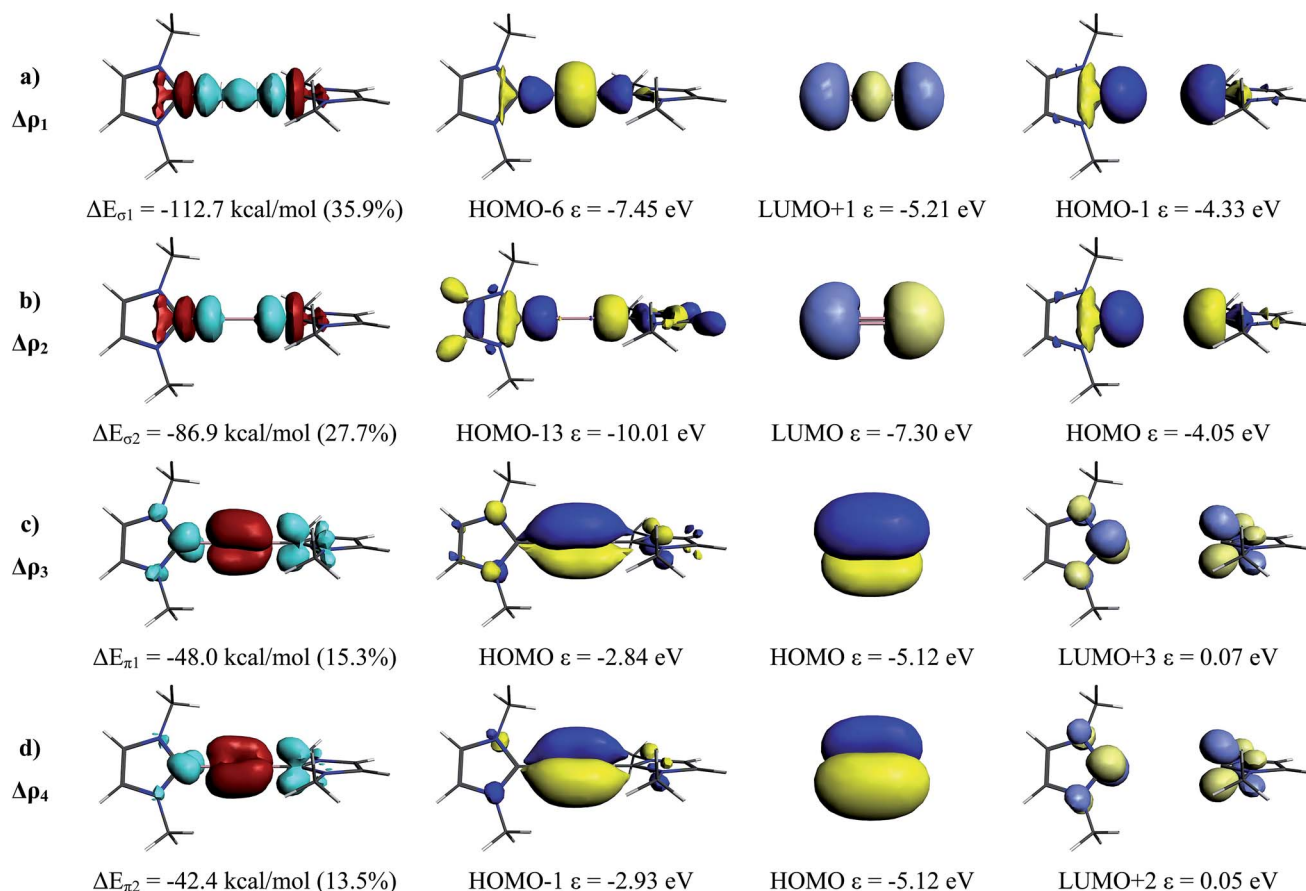

Fig. 3 Plot of the interacting donor and acceptor orbitals and calculated eigenvalues  $\epsilon$  of  $(NHC^{Me})_2$  and  $(\Sigma_g^+)_2$   $B_2$  (right two columns) and matching MOs of the complex  $NHC^{Me} \rightarrow B \equiv B \leftarrow NHC^{Me}$  (second column from the left). Plot of the deformation densities  $\Delta\rho$  with connected stabilization energies  $\Delta E$  of the four most important orbital interactions in  $B_2(NHC^{Me})_2$  which indicate the associated charge flow red  $\rightarrow$  blue.

Finally, we want to point out that two recent papers by Braunschweig just appeared where the strength of the B–B triple bond in the original diboryne  $B_2(NHC^R)_2$  and in the slightly changed species  $B_2(NHC^R)_2$  with slightly less bulky substituents  $R'$  than  $R$  has experimentally been assessed.<sup>30</sup> One paper shows that the observed B–B stretching modes of the Raman spectra nicely fit into the established trend of the  $C \equiv C$  and  $N \equiv N$  stretching frequencies of alkynes and dinitrogen.<sup>30a</sup> The second paper reports  $^{11}B$ – $^{11}B$  spin–spin ( $J$ ) coupling constants which indicate that the bonding description in terms of a triple bond is justified.<sup>30b</sup> Thus, theory and experiment agree that  $B_2(NHC^R)_2$  contains has significant boron–boron triple bond character.

## Summary and conclusion

The results of this work can be summarized as follows. The calculated data and the thorough bonding analysis of the compound  $B_2(NHC^{Me})_2$  provide convincing evidence for the appearance of significant boron–boron triple bond character in the model compound and in the isolated diboryne  $B_2(NHC^R)_2$  of Braunschweig which has an even slightly shorter B–B bond. The bonding situation is best described in terms of  $NHC^{Me} \rightarrow B_2 \leftarrow$

$NHC^{Me}$  donor–acceptor interactions and concomitant  $\pi$ -back-donation  $NHC^{Me} \leftarrow B_2 \rightarrow NHC^{Me}$  which weakens the B–B bond, but the essential features of a triple bond are preserved. An appropriate formula which depicts both interactions is the sketch  $NHC^{Me} \rightleftharpoons B \equiv B \rightleftharpoons NHC^{Me}$ .

Calculations of the stretching force  $F_{BB}$  constants which take molecules that have genuine single, double and triple bonds suggest that the effective bond order of  $B_2(NHC^{Me})_2$  has the value of 2.34. The suggestion by Köppe and Schnöckel that the strength of the boron–boron bond in  $B_2(NHC^H)_2$  is only between a single and a double bond which should be described with a Lewis structure that has a  $\sigma$  bond and a delocalized  $\pi$  bond is repudiated. It misleadingly takes the force constant  $F_{BB}$  of OBBO as reference value for a B–B single bond which ignores  $\pi$  bonding contributions. The alleged similarity between the B–O bonds in OBBO and the B–C bonds in  $B_2(NHC^{Me})_2$  is a mistaken application of the principle of isolable relationship.

## Acknowledgements

We appreciate critical and constructive comments of the referees which were very helpful to improve the paper. This work was supported by the Deutsche Forschungsgemeinschaft.
