# Photocatalytic oxidation of iron(II) complexes by dioxygen using 9-mesityl-10-methylacridinium ions†

Takeshi Tsudaka,<sup>a</sup> Kei Ohkubo<sup>\*ab</sup> and Shunichi Fukuzumi<sup>\*abc</sup>

Photocatalytic oxidation of iron(II) complexes by dioxygen occurred using the organic photocatalysts, 9-mesityl-10-methylacridinium ions ( $\text{Acr}^+-\text{Mes}$ ) and 2-phenyl-4-(1-naphthyl) quinolinium ions ( $\text{QuPh}^+-\text{NA}$ ), in the presence of triflic acid in acetonitrile under visible light irradiation. The electron-transfer state of  $\text{Acr}^+-\text{Mes}$  produced upon photo-excitation oxidized the iron(II) complexes, whereas it reduced dioxygen with protons to produce iron(III) complexes and  $\text{H}_2\text{O}_2$ .

Metal complexes are usually oxidized by inorganic oxidants such as cerium ammonium nitrate and lead dioxide.<sup>1–5</sup> In such cases, stoichiometric amounts of inorganic oxidants are required to obtain oxidized metal complexes, producing inorganic wastes which cause environmental problems. The ideal oxidant, which is environmentally benign, is dioxygen ( $\text{O}_2$ ), producing only hydrogen peroxide or water as the reduced product. However, the oxidation of metal complexes by  $\text{O}_2$  is often endergonic even in the presence of an acid. Thus, an appropriate photocatalyst is required for the oxidation of metal complexes by  $\text{O}_2$  in the presence of an acid. Ruthenium(II) complexes, such as  $[\text{Ru}(\text{bpy})_3]^{2+}$  ( $\text{bpy} = 2,2'$ -bipyridine) are known to be oxidized by  $\text{O}_2$  in the presence of an acid to yield the corresponding Ru(III) complexes.<sup>6,7</sup> On the other hand, organic photocatalysts have merited increasing attention for a variety of oxidation reactions.<sup>8–14</sup> However, there has been no report on photocatalytic oxidation of metal complexes by  $\text{O}_2$  using organic photocatalysts.

We report herein the photocatalytic oxidation of iron(II) complexes by  $\text{O}_2$  using 9-mesityl-10-methylacridinium ions ( $\text{Acr}^+-\text{Mes}$ )<sup>15</sup> and 2-phenyl-4-(1-naphthyl)quinolinium ions ( $\text{QuPh}^+-\text{NA}$ )<sup>16</sup> as

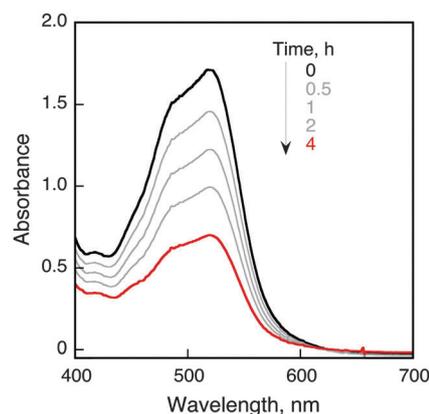

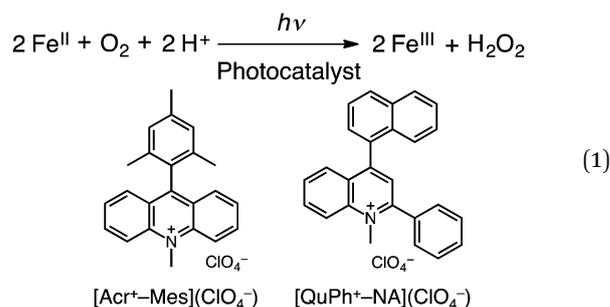

Fig. 1 Visible absorption change in photocatalytic oxidation of  $[\text{Fe}^{\text{II}}(\text{bpy})_3]^{2+}$ - $(\text{PF}_6^-)_2$  (2.0 mM) by  $\text{O}_2$  in  $\text{O}_2$ -saturated MeCN in the presence of  $[\text{Acr}^+-\text{Mes}](\text{ClO}_4^-)$  (0.20 mM) and HOTf (0.10 M) at 298 K under visible light irradiation using a xenon lamp with a cut filter ( $\lambda < 390$  nm).

organic photocatalysts in the presence of triflic acid (HOTf) in acetonitrile (MeCN) under visible light irradiation [eqn (1)]. Visible light irradiation of  $\text{O}_2$ -saturated acetonitrile is shown in Fig. 1, where the absorption band at 520 nm due to  $[\text{Fe}^{\text{II}}(\text{bpy})_3]^{2+}$  decreased, accompanied by the increase in absorption at 650 nm due to  $[\text{Fe}^{\text{III}}(\text{bpy})_3]^{3+}$ .  $[\text{Fe}^{\text{II}}(\text{bpy})_3]^{2+}$  was not oxidized without  $\text{Acr}^+-\text{Mes}$  under irradiation (Fig. S1 and S2 in the ESI†). The reduced product of  $\text{O}_2$  was  $\text{H}_2\text{O}_2$ , which was detected by spectral titration with the use of the oxo[5,10,15,20-tetra(4-pyridyl)porphyrinato]titanium(IV) complex (see the Experimental section in the ESI†).<sup>17</sup>

† Electronic supplementary information (ESI) available: Experimental and kinetic details. See DOI: 10.1039/c6cc00359a

The photocatalytic oxidation of other iron(II) complexes by O<sub>2</sub> was examined in the presence of HOTf in O<sub>2</sub>-saturated MeCN (Fig. S3–S6 in the ESI†). The quantum yields of formation of iron(III) complexes were determined using a ferrioxalate actinometer (see Fig. S7–S9 and the Experimental section in the ESI†).<sup>18</sup> The quantum yields ( $\Phi$ ) of photocatalytic oxidation of iron(II) complexes by O<sub>2</sub> in the presence of HOTf in MeCN are listed in Table 1 together with the concentrations of iron(II) complexes, HOTf and O<sub>2</sub>, the one-electron oxidation potentials of iron(II) complexes ( $E_{\text{ox}}$ )<sup>19</sup> and the free energy change of the oxidation ( $\Delta G_{\text{ox}}$ ). The  $\Delta G_{\text{ox}}$  values were evaluated from the  $E_{\text{ox}}$  values and the  $E_{\text{red}}$  value of O<sub>2</sub> in the presence of an acid in MeCN (0.75 V vs. SCE) [eqn (2)].<sup>20</sup>

$$\Delta G_{\text{ox}} = -2e(E_{\text{red}} - E_{\text{ox}}) \quad (2)$$

Judging from the  $\Delta G_{\text{ox}}$  values, the photocatalytic oxidation of [Fe<sup>II</sup>(Clphen)<sub>3</sub>]<sup>2+</sup>, [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup> and [Fe<sup>II</sup>(Me<sub>2</sub>bpy)<sub>3</sub>]<sup>2+</sup> is endergonic, whereas that of Fe<sup>II</sup>(BrC<sub>5</sub>H<sub>4</sub>)<sub>2</sub> and Fe<sup>II</sup>(BrC<sub>5</sub>H<sub>4</sub>)(C<sub>5</sub>H<sub>5</sub>) is exergonic. The  $\Phi$  values increased with the decreasing the  $E_{\text{ox}}$  values of iron(II) complexes as the free energy change of the reaction in eqn (1) decreased to be thermodynamically more favourable. Dependence of  $\Phi$  on concentrations of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>(PF<sub>6</sub><sup>-</sup>)<sub>2</sub>, HOTf and O<sub>2</sub> is shown in Fig. 2 (parts a, b and c, respectively). The  $\Phi$  value became constant with the increasing concentrations of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>(PF<sub>6</sub><sup>-</sup>)<sub>2</sub>, HOTf and O<sub>2</sub>, respectively. The photocatalytic oxidation of iron(II) complexes is enhanced by using QuPh<sup>+</sup>-NA instead of Acr<sup>+</sup>-Mes as shown in Table 1. (Fig. S10–S14 in the ESI†).

Nanosecond laser flash photolysis measurements were performed in order to clarify the catalytic mechanism for photocatalytic oxidation of iron(II) complexes by O<sub>2</sub> using Acr<sup>+</sup>-Mes in the presence of HOTf in MeCN. Transient absorption spectra were taken after the nanosecond laser excitation at 355 nm of a deaerated MeCN solution of Acr<sup>+</sup>-Mes in the absence and presence of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>(PF<sub>6</sub><sup>-</sup>)<sub>2</sub> as shown in Fig. 3. The transient absorption band at 490 nm is due to the electron-transfer state of Acr<sup>+</sup>-Mes. In the presence of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup> the absorption at 490 nm decayed more rapidly and the decay rate increased with the increasing concentration of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>. The decay rate obeyed pseudo-first-order kinetics and the pseudo-first order rate constant increased linearly with the increasing concentration of [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>(PF<sub>6</sub><sup>-</sup>)<sub>2</sub>. From the slope the rate constant ( $k_{\text{ox}}$ ) of electron transfer from [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup> to the electron-transfer state of Acr<sup>+</sup>-Mes was determined to be

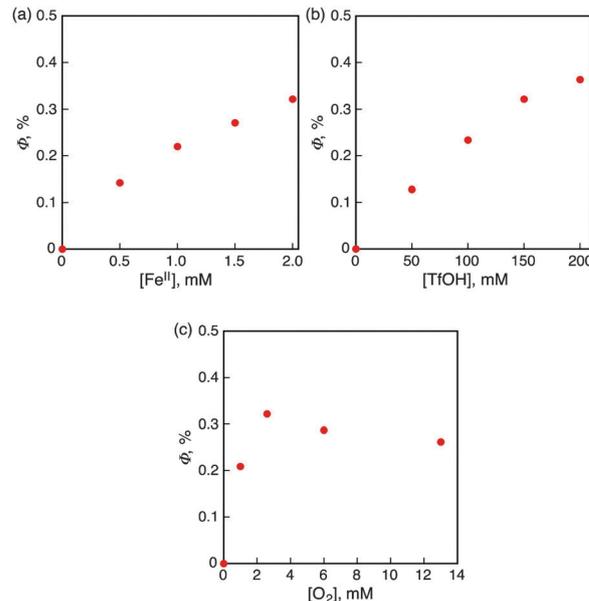

Fig. 2 Dependence of  $\Phi$  on concentrations of (a) [Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>, (b) HOTf and (c) O<sub>2</sub>. Standard conditions: [[Acr<sup>+</sup>-Mes](ClO<sub>4</sub><sup>-</sup>)] = 1.0 mM; [[Fe<sup>II</sup>(bpy)<sub>3</sub>]<sup>2+</sup>(PF<sub>6</sub><sup>-</sup>)<sub>2</sub>] = 2.0 mM; [HOTf] = 0.15 M; [O<sub>2</sub>] = 2.6 mM; dehydrated MeCN (0.40 mL); cell path length 0.1 cm; excitation wavelength: 420 nm.

$3.7 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$  as shown in the inset of Fig. 3. Similarly the  $k_{\text{ox}}$  values of other iron(II) complexes were determined (see Fig. S15–S23 in the ESI†) as listed in Table 2 together with the  $E_{\text{ox}}$  values. The  $k_{\text{ox}}$  value increases with the decreasing  $E_{\text{ox}}$  values. In the presence of O<sub>2</sub>, electron transfer from the electron-transfer state of Acr<sup>+</sup>-Mes to O<sub>2</sub> is known to occur with a rate constant of  $6.8 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ .<sup>21</sup> The rate constant of electron transfer from the electron-transfer state of QuPh<sup>+</sup>-NA to O<sub>2</sub> was determined to be  $6.3 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$  (see Fig. S24 in the ESI†). Thus, the photocatalytic oxidation of iron(II) complexes (Fe<sup>II</sup>) by O<sub>2</sub> in the presence of HOTf proceeds as shown in Scheme 1. Photoexcitation of Acr<sup>+</sup>-Mes results in the formation of the electron-transfer state of Acr<sup>+</sup>-Mes, which oxidizes iron(II) complexes to iron(III) complexes and reduces O<sub>2</sub> with protons to produce HO<sub>2</sub><sup>•</sup>, which disproportionates to yield H<sub>2</sub>O<sub>2</sub>.

In conclusion, iron(II) complexes are oxidized to iron(III) complexes by O<sub>2</sub> using Acr<sup>+</sup>-Mes as an organic photocatalyst in the presence of HOTf in MeCN under visible light irradiation *via* electron-transfer oxidation of iron(II) complexes and reduction of

Scheme 1 Photocatalytic cycle for oxidation of iron(II) complexes to iron(III) by  $\text{O}_2$  with  $\text{Acr}^+-\text{Mes}$ .

$\text{O}_2$  by the electron-transfer state of  $\text{Acr}^+-\text{Mes}$  produced upon photoexcitation of  $\text{Acr}^+-\text{Mes}$ , respectively. The present study provides an environmentally benign approach for oxidation of metal complexes by  $\text{O}_2$  to obtain the oxidised metal complexes and hydrogen peroxide ( $\text{H}_2\text{O}_2$ ). Because there are many synthetically useful oxidation reactions using  $\text{H}_2\text{O}_2$ ,<sup>22</sup> this study has paved a new

way for photocatalytic oxidation of substrates by  $\text{O}_2$  with organic photocatalysts and iron(II) complexes.
