**A new reaction mode for bicyclo[1.1.0]tetraphosphabutanes is reported. The C=S and C=N bonds of phenyl isothiocyanate reversibly insert into a P–P bond of  $[(\text{CpNi}(\text{IMes}))_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-P}_4)]$  ( $\mathbf{1}^{\text{Mes}}$ , IMes = 1,3-bis(2,4,6-trimethylphenyl)imidazolin-2-ylidene), forming isomers **2a** and **2b**. X-ray crystallography and  $^{31}\text{P}\{^1\text{H}\}$  NMR spectroscopy revealed similar bicyclo[3.1.0]heterohexane structures for these compounds.**

Developing new, targeted and selective methods for the functionalisation of the  $\text{P}_4$  molecule remains a topical challenge despite the extensive research efforts carried out in the past.<sup>1,2</sup> Recent reports have focused on the use of nucleophilic carbanions and carbenes,<sup>3,4</sup> insertion reactions of p-block elements, *e.g.* phosphonium cations<sup>5</sup> and the use of main group element or transition metal-based radicals.<sup>6,7</sup> The latter approach often gives rise to bicyclo[1.1.0]tetraphosphabutanes **A**, which may be seen as potential intermediates on the way to a stepwise  $\text{P}_4$  degradation sequence (Scheme 1a). While various ‘ $\text{P}_4$  butterfly’ compounds of type **A** are known, it is interesting to note that their reactivity has only been explored to a small extent (Scheme 1b).<sup>1,6–9</sup> Previous studies mainly focused on iron complexes.<sup>1d,7a,c,9–11</sup> As reported by Scherer and Scheer, thermolysis or photolysis of  $[(\text{Cp}^R\text{Fe}(\text{CO}))_2(\mu\text{-}\eta^1\text{:}\eta^1\text{-P}_4)]$  ( $\text{Cp}^R = \text{C}_5\text{H}_2\text{-1,2,4-}t\text{Bu}_3$ ,  $\text{C}_5\text{H}_2\text{-1,2,4-}t\text{Bu}_3$ ,  $\text{C}_9\text{H}_5\text{-1,3-}t\text{Bu}_2$  and  $\text{C}_5\text{iPr}_5$ ) affords mixtures of polyphosphido complexes.<sup>7a,c</sup> Reactions with (phospha)alkynes evoked the  $\text{P}_3/\text{P}_1$  fragmentation of the bicyclo[1.1.0]tetraphosphabutane diyl fragment, forming phosphide, phospholide and diphosphacyclobutadiene components.<sup>9,10</sup> Further studies revealed that the ‘ $\text{P}_4$  butterfly’ may be protonated reversibly and coordinates as a chelate ligand to copper(i).<sup>11</sup> Here, we disclose a new reaction mode for metal-substituted bicyclo[1.1.0]tetraphosphabutanes. We have found

that phenyl isothiocyanate reversibly inserts into a P–P bond of the bicyclo[1.1.0]tetraphosphabutane scaffold of the dinuclear nickel complex  $[(\eta^5\text{-Cp})\text{Ni}(\text{IMes})_2(\mu\text{-}\eta^1\text{:}\eta^1\text{-P}_4)]$  ( $\mathbf{1}^{\text{Mes}}$ , Scheme 1c).<sup>7b</sup> This unprecedented reaction affords the isomers **2a** and **2b**, which display a bicyclo[3.1.0]heterohexane skeleton. We describe the single-crystal X-ray structures and  $^{31}\text{P}\{^1\text{H}\}$  NMR data of these

**Scheme 1** (a) Formation of bicyclo[1.1.0]tetraphosphabutanes amenable for further transformations; (b) selected reactions of iron-substituted bicyclo[1.1.0]tetraphosphabutanes;  $\text{Cp}^R = \text{C}_5\text{H}_2\text{-1,2,4-}t\text{Bu}_3$ ,  $\text{C}_5\text{H}_2\text{-1,2,4-}t\text{Bu}_3$ ,  $\text{C}_9\text{H}_5\text{-1,3-}t\text{Bu}_2$ ,  $\text{C}_5\text{iPr}_5$ ,  $\text{R}^1 = \text{R}^2 = \text{Me, Ph}$ ;  $\text{R}^1 = \text{H}$ ,  $\text{R}^2 = \text{Ph, }t\text{Bu, SiMe}_3$ ,  $\text{CO}_2\text{Me/Et}$ ,  $\text{R}^3 = t\text{Bu, C}(\text{CH}_2)_5\text{Me}$ ; (c) synthesis of  $\mathbf{1}^{\text{Dipp}}$  and  $\mathbf{1}^{\text{Mes}}$  and reactivity toward phenyl isothiocyanate.<sup>6–10</sup>

new complexes and analyse the possible nature of additional reaction products using DFT calculations.

We recently synthesised the first nickel-substituted bicyclo[1.1.0]tetraphosphabutane,  $[(\eta^5\text{-Cp})\text{Ni}(\text{IDipp})_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-P}_4)]$  (**1<sup>Dipp</sup>**, IDipp = 1,3-bis(2,6-diisopropylphenyl)imidazolin-2-ylidene).<sup>7b</sup> This complex is formed in a quantitative reaction from two equivalents  $[(\eta^5\text{-Cp})\text{Ni}(\text{IDipp})]$  and  $\text{P}_4$  (Scheme 1c). Subsequent work showed that the slightly less encumbered mesityl-substituted complex  $[(\eta^5\text{-Cp})\text{Ni}(\text{IMes})_2(\mu\text{-}\eta^1\text{-}\eta^1\text{-P}_4)]$  (**1<sup>Mes</sup>**) is obtained in an analogous fashion. **1<sup>Mes</sup>** was isolated as dark red air-sensitive crystals in 71% yield (Scheme 1c) and shows a better solubility than **1<sup>Dipp</sup>**, dissolving well in benzene, toluene, diethyl ether and tetrahydrofuran (ESI<sup>†</sup>).

In order to probe the reactivity of **1<sup>Dipp</sup>** and **1<sup>Mes</sup>**, we investigated reactions with heteroallenes. ADMX spin systems were observed by  $^{31}\text{P}$  NMR spectroscopy with  $\text{CS}_2$  (10 equiv.), suggesting an insertion into a P-P bond, but the products could not be isolated (ESI<sup>†</sup>). Isolable products were obtained with phenyl isothiocyanate, however. Monitoring the reaction of **1<sup>Mes</sup>** and PhNCS in  $[\text{D}_8]\text{THF}$  (Fig. 1) revealed that 7 equiv. PhNCS were necessary for full conversion of **1<sup>Mes</sup>** after four hours, while a large amount of **1<sup>Mes</sup>** (55%) remained in the reaction mixture with one equiv. PhNCS after one day (Fig. S10, ESI<sup>†</sup>). Two main products **2a** and **2b** (ADMX spin systems) and one minor species **2c** were detected (approximate ratio **2a** : **2b** : **2c** 75 : 20 : 5).<sup>‡</sup> The simultaneous formation of **2a**, **2b** and **2c** commences below 0 °C according to a VT NMR study ( $[\text{D}_8]\text{THF}$ , Fig. S8, ESI<sup>†</sup>). Prolonged reaction times and heating of the solution resulted in essentially the same product ratio, although the signal to noise ratio of the spectra decreased over time. In contrast, the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum of the reaction of **1<sup>Dipp</sup>** with a large excess of PhNCS in  $[\text{D}_8]\text{THF}$  after two days at room temperature showed signals of a species similar to **2b** (15%, ADMX spin system), **1<sup>Dipp</sup>** (50%) and  $\text{P}_4$  (35%) (Fig. S9, ESI<sup>†</sup>).

Complex **2a** can be isolated as an analytically pure, dark brown solid in 31% yield by crystallising the crude product twice from toluene/n-hexane (ESI<sup>†</sup>). Crystallisation of the crude product from diethyl ether and recrystallization from toluene/n-hexane affords pure, crystalline **2b** in 16% isolated yield. Single-crystal XRD for **2a** (Fig. 2, top) revealed an unusual nickel-substituted bicyclo[3.1.0]-2-thia-1,4,5,6-tetraphosphahexane

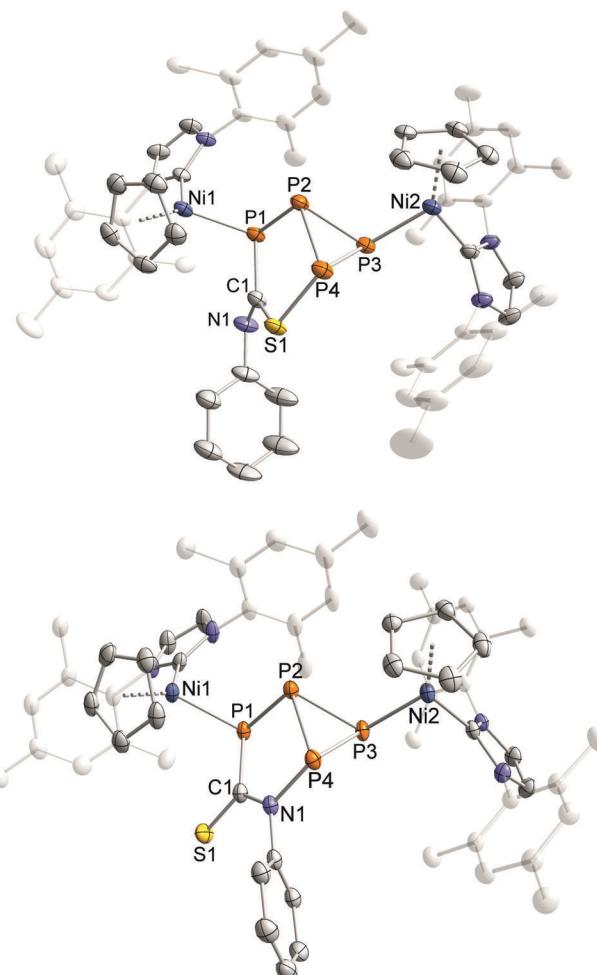

Fig. 2 Solid-state molecular structures of **2a** (top) and **2b** (bottom). The hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn at 40% level. Selected bond lengths (Å) and angles (°) for **2a**: P1–C1 1.860(4), P4–S1 2.1257(13), P1–P2 2.1818(14), P2–P3 2.2182(15), P2–P4 2.2222(14), P3–P4 2.1935(15), C1–S1 1.794(4), C1–N1 1.278(6), Ni1–P1 2.2036(13), Ni2–P3 2.1906(11), P1–P2–P4 102.89(5), P2–P4–S1 102.86(6), P4–S1–C1 104.82(14), S1–C1–P1 122.3(2), C1–P1–P2 102.88(14), P3–P2–P4 59.20(5), P1–C1–N1 116.4(3), S1–C1–N1 121.3(2); for **2b**: P1–C1 1.828(3), P4–N1 1.785(3), P1–P2 2.2157(11), P2–P4 2.1969(10), P2–P3 2.2233(10), P3–P4 2.206(1), C1–N1 1.359(4), C1–S1 1.678(3), Ni1–P1 2.2188(9), Ni2–P3 2.2192(9), P1–P2–P4 95.28(4), P2–P4–N1 99.75(9), P4–N1–C1 124.9(2), N1–C1–P1 118.6(2), C1–P1–P2 100.48(3), P3–P2–P4 59.88(3), P1–C1–S1 117.68(18), N1–C1–S1 123.6(2).

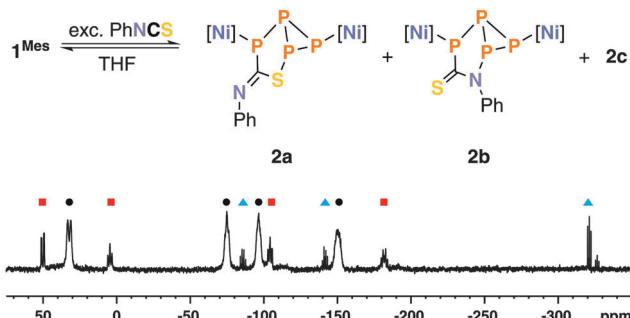

Fig. 1 Synthesis of **2a** and **2b** (top), and  $^{31}\text{P}\{^1\text{H}\}$  NMR spectrum ( $[\text{D}_8]\text{THF}$ ) of the reaction of PhNCS and **1<sup>Mes</sup>** (7 : 1) at room temperature after four hours; ● = **2a**, ■ = **2b**, ▲ = **2c** (bottom).

moiety (P1–C1 1.860(4) Å, P4–S1 2.1257(13) Å) with an exocyclic imino function. The C1–N1 (1.278(6) Å) and S1–C1 (1.794(4) Å) bonds of **2a** are elongated compared to free aryl isothiocyanates.<sup>12</sup> The P–P distances (2.1818(14)–2.2222(14) Å) are in the range of single bonds.<sup>7</sup> The five-membered  $\text{CP}_3\text{S}$  heterocycle (P1–P2–P4–S1–C1) is almost flat ( $\sum_{\text{angles}} = 535.8^\circ$ ) and orthogonal ( $89.60(7)^\circ$ ) to the plane formed by P2, P3 and P4. The scaffold of **2a** is analogous to that of 2,3,4,6-tetra-*tert*-butylbicyclo[3.1.0]hexaphosphane synthesised by Baudler *et al.*<sup>13</sup>

The molecular structure of the regio isomer **2b** (Fig. 2, bottom) features a flat  $\text{CNP}_3$  heterocycle ( $\sum_{\text{angles}} = 539.0^\circ$ ) with a thioketone function (C1–S1 1.678(3) Å) and single bonds

between P1–C1 (1.828(3) Å) and P4–N1 (1.785(3) Å). The P–P distances in **2b** (2.1969(10)–2.2233(10) Å) are similar to those of **2a**. The CNP<sub>3</sub> ring forms an acute dihedral angle of 79.58(5)° with the P2–P3–P4 plane.

The <sup>31</sup>P{<sup>1</sup>H} NMR spectrum of **2a** ([D<sub>8</sub>]THF, room temperature) features four broad multiplets at –150.1, –96.4, –75.0 and 32.1 ppm consistent with four chemically different P atoms. The signals are broad at room temperature (average half-width  $\tau_{\text{FWHM}} = 565$  Hz); they become sharper when the temperature is decreased to –80 °C (av.  $\tau_{\text{FWHM}} = 35$  Hz). Experimental and fitted <sup>31</sup>P{<sup>1</sup>H} NMR spectra in [D<sub>8</sub>]THF at –80 °C along with the assignment of the chemical shifts and coupling constants are shown in Fig. 3. The resonance at –151.8 ppm is assigned to P<sub>A</sub> connected to three P atoms based on the observation of three large <sup>1</sup>J(P,P)-coupling constants for this multiplet (<sup>1</sup>J(P<sub>APD</sub>) = –178 Hz, <sup>1</sup>J(P<sub>APM</sub>) = –185 Hz and <sup>1</sup>J(P<sub>APX</sub>) = –374 Hz). The P atoms coordinated to nickel ( $\delta(P_D) = –105.5$  ppm;  $\delta(P_X) = 27.8$  ppm) show a common large <sup>2</sup>J(P,P) coupling (<sup>2</sup>J(P<sub>D</sub>,P<sub>X</sub>) = 82 Hz), which may arise from an interaction of the lone pairs due to the conformational constraints of the bicyclo[3.1.0]heterohexane skeleton.<sup>13</sup>

Complex **2b** gives rise to four slightly broad <sup>31</sup>P{<sup>1</sup>H} NMR resonances at –182.1, –104.5, 4.5 and 50.1 ppm in [D<sub>8</sub>]THF at

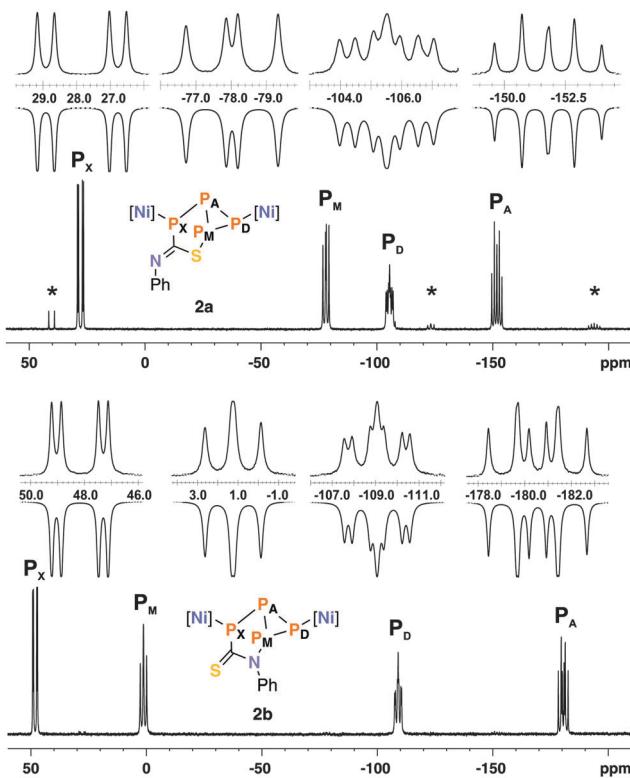

Fig. 3 <sup>31</sup>P{<sup>1</sup>H} NMR spectra of **2a** (top) and **2b** (bottom, 161.98 MHz, [D<sub>8</sub>]THF, 193 K); **2a** (ADMX spin system):  $\delta_A = –151.8$  ppm,  $\delta_D = –105.5$  ppm,  $\delta_M = –78.0$  ppm,  $\delta_X = 27.8$  ppm, <sup>1</sup>J(P<sub>APD</sub>) = –178 Hz, <sup>1</sup>J(P<sub>APM</sub>) = –185 Hz, <sup>1</sup>J(P<sub>APX</sub>) = –374 Hz, <sup>1</sup>J(P<sub>D</sub>P<sub>M</sub>) = –238 Hz, <sup>2</sup>J(P<sub>D</sub>P<sub>X</sub>) = 82 Hz, <sup>2</sup>J(P<sub>M</sub>P<sub>X</sub>) = 9 Hz; **2b** (ADMX spin system):  $\delta_A = –180.5$  ppm,  $\delta_D = –109.1$  ppm,  $\delta_M = 12$  ppm,  $\delta_X = 48.2$  ppm, <sup>1</sup>J(P<sub>APD</sub>) = –193 Hz, <sup>1</sup>J(P<sub>APM</sub>) = –209 Hz, <sup>1</sup>J(P<sub>APX</sub>) = –282 Hz, <sup>1</sup>J(P<sub>D</sub>P<sub>M</sub>) = –237 Hz, <sup>2</sup>J(P<sub>D</sub>P<sub>X</sub>) = 57 Hz, <sup>2</sup>J(P<sub>M</sub>P<sub>X</sub>) = 10 Hz; expansions (inset) show the experimental (up) and fitted spectra (down). The signals assigned to **2b** are labeled with an asterisk.

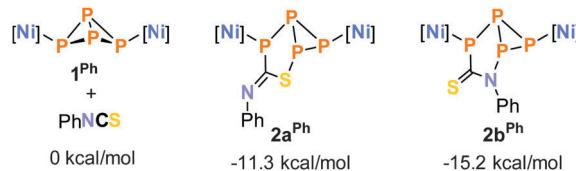

Fig. 4 Calculated, relative Gibbs free energies (kcal mol<sup>–1</sup>) of **1<sup>Ph</sup>**, **2a<sup>Ph</sup>** and **2b<sup>Ph</sup>**. The relative Gibbs free energies refer to **1<sup>Ph</sup>** + PhNCS (kcal mol<sup>–1</sup>).

room temperature. The line width decreased from an average of  $\tau_{\text{FWHM}} = 33$  Hz at room temperature to  $\tau_{\text{FWHM}} = 23$  Hz upon cooling to –80 °C. The chemical shifts and coupling constants of **2b** lie in a similar range as observed for **2a** (Fig. 3, bottom) in agreement with the similar structure motif.

<sup>31</sup>P{<sup>1</sup>H} NMR studies indicate that the formation of **2a**, **2b** and **2c** is reversible; *i.e.* the products slowly equilibrate with the starting material **1<sup>Mes</sup>** in solution (ESI†). A mixture of **2a** (89%), **1<sup>Mes</sup>** (7%), **2c** (4%) and **2b** (traces) was detected upon storing a [D<sub>8</sub>]THF solution of pure **2a** in an NMR tube at room temperature for two days, while a 65:10:5:20 mixture (**2a**:**2b**:**2c**:**1<sup>Mes</sup>**) was present after one week.§ Additional multiplets of unidentified minor species can be observed upon prolonged storage (Fig. S11, ESI†). **2b** behaves similarly (Fig. S12, ESI†). IR monitoring of the decomposition of **2a** ([D<sub>8</sub>]THF, 60 °C, 13.5 hours) shows the formation of free PhNCS (Fig. S13, ESI†).

DFT calculations (ωB97X-D/6-311G(d,p) level)<sup>14</sup> were performed to gain additional insight into the thermodynamics of the reaction. The optimized structures of the truncated model complexes **1<sup>Ph</sup>**, **2a<sup>Ph</sup>** and **2b<sup>Ph</sup>**, where the Mes substituents were replaced by phenyl groups for computational efficiency, are in good agreement with the experimental structures (Fig. 4). The formation of **2a<sup>Ph</sup>** and **2b<sup>Ph</sup>** is exergonic, and the thermodynamic product of the reaction appears to be **2b<sup>Ph</sup>** (–15.2 kcal mol<sup>–1</sup> with respect to the starting materials), while **2a<sup>Ph</sup>** (–11.3 kcal mol<sup>–1</sup>) is a kinetic product.¶

In conclusion, the reaction of **1<sup>Mes</sup>** with PhNCS affords the novel complexes **2a** and **2b** with an unusual bicyclo[3.1.0]heterohexane skeleton. To our knowledge, this represents the first example of an insertion of a heteroallene into a P–P bond of a cyclopolypyrophane. In future work, it will be of interest to investigate whether similar reactions with polar multiple bonds offer a general route toward “functionalized” polyphosphanes.<sup>15</sup> Efficient preparative methods exist for a range of bicyclo[1.1.0]tetraphosphabutanes,<sup>1,6–9</sup> therefore, such transformations may provide a fruitful avenue to the stepwise and selective degradation of the P<sub>4</sub> molecule.

We thank B. Sc. Thomas Maier for experimental assistance. Funding by the Deutsche Forschungsgemeinschaft is gratefully acknowledged.

## Notes and references

‡ <sup>31</sup>P{<sup>1</sup>H} NMR data of **2c** ([D<sub>8</sub>]THF, A<sub>2</sub>MX spin system):  $\delta = –321.2$  (dd, 2P, P<sub>A</sub>, <sup>1</sup>J(P<sub>APM</sub>) = –178 Hz, <sup>1</sup>J(P<sub>APX</sub>) = –188 Hz, –141.5 (dt, 1P, P<sub>M</sub>, <sup>2</sup>J(P<sub>M</sub>P<sub>X</sub>) = 208 Hz), –85.8 (dt, 1P, P<sub>X</sub>) ppm.

§ The <sup>1</sup>H NMR spectrum of a freshly prepared [D<sub>8</sub>]THF solution of pure crystals of **2a** stored for one week at room temperature in an Ar-filled glove box also showed a mixture containing **2a**, **2b** and **1<sup>Mes</sup>** in a 94.5:0.5:5 ratio.

The structure and the mechanism of formation of the minor product **2c** ( $A_2MX$  spin system, *vide supra*) presently remains unclear. Five potential candidates were identified by our computations (Fig. S14, ESI†). These calculated isomers are adducts of the starting material with PhNCS ( $2c^{Add1}$  and  $2c^{Add2}$ ) or result from the insertion of the C=S or C≡N double bonds into the Ni–P bond ((E)- $2c^{Ins1}$ , (Z)- $2c^{Ins1}$  and  $2c^{Ins2}$ ).<sup>16</sup> Each of them has an energy significantly higher than that of **2a<sup>Ph</sup>** and **2b<sup>Ph</sup>**.
