We report a traceless photocleavable linker for the automated glycan assembly of carbohydrates with free reducing ends. The reductive-labile functionality in the linker tolerates all commonly used reagents and protocols for automated glycan assembly, as demonstrated with the successful preparation of nine plant cell wall-related oligosaccharides, and is cleaved by hydrogenolysis.

Carbohydrates play a central role in materials science, biology and medicine.¹ In order to study the structure–activity relationship of glycans, homogeneous and pure samples which are obtained through chemical synthesis are indispensable. Automated glycan assembly has evolved as a platform to rapidly access these complex glycans.² The automated process assembles a diverse set of mono-saccharide building blocks into oligosaccharide products without the need for manual intervention. Starting from a resin-bound linker, iterative glycosylation and deprotection steps systematically elongate the glycan chain. Photolabile linker **1** (cf. Fig. 1) is often employed to link the growing glycan to the solid support.³ This linker is cleaved in a continuous flow photoreactor followed by global deprotection to release glycans containing an aminoalkyl-linker at the reducing end. The amino group of the alkyl linker is utilized to attach glycans to microarray surfaces⁴ and carrier proteins required in the study and development of conjugate vaccine candidates.⁵

Naturally occurring free reducing glycans are also highly desirable, since synthetic samples are frequently needed as standards for LC/MS measurements⁶ or biological assays that do not tolerate the presence of unnatural modifications. To access glycans with free reducing ends by solid-phase chemistry, base-labile linker systems have been used that incorporate a

benzyl group to release the anomeric hydroxyl after a final hydrogenation step.⁷ Based on this precedence, we envisioned that the introduction of a benzyl moiety into photocleavable linker **1** would allow for rapid access to free reducing glycans after photo-induced cleavage of the glycans from the solid support followed by hydrogenolysis. Here, we report the synthesis and use of traceless linker **2**, whose applicability was demonstrated in the automated assembly of various complex glycans with free reducing ends (Fig. 1).

Following the established route towards photo-cleavable linker **1**, the preparation of **2** required only the substitution of the 5-aminopentanol portion for benzylic aminoalcohol **5**, which is commercially available but very expensive. We designed a short and scalable route towards aminoalcohol **5** that provides an attractive alternative to the available literature procedures.⁸ Readily available terephthalaldehyde (**3**) was selectively reduced once with NaBH₄ and condensed with nitromethane in an Henry reaction to form nitroalkene **4**.^{9,10} Subsequent conjugate reduction of the nitroalkene with NaBH₄ in DMSO gave the corresponding nitroalkane (not shown) which was further reduced to the primary amine by hydrogenation and then isolated as its

Scheme 1 Gram-scale preparation of the resin-bound linker **2**.

hydrochloride salt **5**. With sufficient quantities of the aminoalcohol in hand, photocleavable linker **7** was obtained by reductive amination of **5** with aryl aldehyde **6** followed by protection of the resulting secondary amine with CbzCl.³ This short route was readily scaled up for the preparation of a seven gram batch of the product. Subsequent functionalization of Merrifield resin by alkylation with four equivalents of linker **7** finally provided resin-bound linker **2** with a loading determined to be approximately 0.26 mmol g^{-1} (Scheme 1).^{3,11} Excess linker **7** was efficiently recovered after functionalization.

The automated assembly of fully-protected cellulose tetrasaccharide **9** was selected as a proof-of-principle study for the utility of the new linker (Scheme 2). The synthesis of **9** included four iterative cycles of glycosylation and Fmoc-deprotection steps employing monosaccharide building block **8**, followed

Scheme 2 Head-to-head comparison of the traceless linker **2** and the aminoalkyl linker **1**. Glycosylation step (a): 3.7 equiv. of **8**, TMSOTf, CH_2Cl_2 , $-35^\circ\text{C} \rightarrow -15^\circ\text{C}$; deprotection step (b): 20% NEt_3 in DMF, 25°C . Yields are based on resin loading.

by photolytic cleavage of the linker from the solid-support prior to final HPLC purification. Target molecule **9** was isolated in 67% yield and thus virtually with the same efficiency as aminopentyl-substituted cellulose derivative **10** that was obtained using linker **1**. Notably, the presence of an additional benzene moiety in the linker did not affect the efficiency of the glycosylation and deprotection steps in the automated assembly as well as the subsequent photolytic cleavage. Next, cellulose tetrasaccharide **9** was sequentially deprotected by methanolysis of the benzoate esters (with NaOMe) followed by hydrogenolysis of the benzyl ethers and the linker (H_2 , Pd/C), affording cellulose tetrasaccharide **11** as a mixture of α/β -anomers. During concentration of the crude product, the open chain form of **11** reacted partially with the primary amine **12** to form a hemiaminal ether.¹² Acidic hydrolysis converts this mixture to the final product **11** before it was subjected to final HPLC purification. As verified by analytical HPLC, MS and 2D NMR spectroscopy, the tetrasaccharide product was obtained in high purity, albeit in a rather low yield (20%) over the two deprotection steps. The moderate yield may be attributed to the low solubility of the partially protected intermediate (not shown), impeding purification by reversed phase-HPLC. The deprotection sequence is currently optimized to increase the overall efficiency of the process (Scheme 3).

The utility of linker **2** was further illustrated by preparing a diverse set of plant cell wall-related oligosaccharides (Scheme 4). Seven orthogonally protected monosaccharide building blocks (BB) **8** and **13–18** were used for the automated glycan assembly of cellulose-, arabinoxylan-, and arabinogalactan-type oligosaccharides.¹³ Following iterative glycosylation and chemoselective deprotection steps, various linear and branched oligosaccharides up to hexasaccharides were obtained after photolytic cleavage from the solid support. These protected products were then subjected to methanolysis and hydrogenation to afford pure glycans **19–26** in 3–18% overall yield. For the automated assembly of the xylan oligosaccharides **20–23**, the use of only 2.8 equiv. of building block per glycosylation step was sufficient, whereas for the construction of the notoriously difficult to synthesize Gal- β -1,3-Gal-linkage (**24–26**) eight equiv. of building block were necessary.^{13b} Linker **2** proved to be compatible with all common protocols for automated glycan assembly, including glycosylations with glycosyl phosphates and thioglycosides, the removal of protecting groups such as Fmoc,

Synthesizer modules (a): one or two cycles of 1.4–4.0 equiv. of **BB**, TMSOTf, CH_2Cl_2 , $-35^\circ C$ or $-30^\circ C$ (5 min) \rightarrow $-15^\circ C$ or $-20^\circ C$ (30 min); (b): two cycles of 1.4–4.0 equiv. of **BB**, NIS/TfOH, CH_2Cl_2 /dioxane (2 : 1), $-40^\circ C$ (5 min) \rightarrow $-20^\circ C$ (40 min); (c): 3 cycles of 20% Et_3N in DMF, $25^\circ C$ (5 min); (d): 3 cycles of $N_2H_4 \cdot HOAc$ (0.15 M) in pyridine/AcOH/ H_2O (4 : 1 : 0.25), $25^\circ C$ (30 min); (e): six cycles of DDQ (0.10 M) in DCE/MeOH/ H_2O (64 : 16 : 1), $40^\circ C$ (20 min); (f): three cycles of Bz_2O (0.50 M in DCE) and DMAP (0.25 M in DCE), pyridine, $40^\circ C$ (30 min). Photolytical cleavage (g): $h\nu$ (305 nm), DCM, rt. Global deprotection (h): NaOMe, MeOH, rt (16 h); (i): H_2 , 10% Pd/C, EtOAc/MeOH/ H_2O /AcOH, rt (16 h). Yields are based on resin loading. The letter codes below the structures represent the synthesizer modules and deprotection steps applied in the respective syntheses.

Lev and Nap, as well as the capping of free hydroxyl groups as benzoyl esters.

In conclusion, we have synthesized nine plant cell wall-related glycans using a novel traceless photocleavable linker that enables the automated glycan assembly of carbohydrates with free reducing ends. The linker complements the photocleavable linker for the synthesis of aminoalkyl-functionalized glycans and provides the oligosaccharides in comparable yields. The opportunity to produce large sets of related glycans with free reducing ends holds great potential for the preparation of standards for LC/MS- and ion mobility mass spectrometry experiments.^{6,14}
