The carboboration of Me$_3$Si-substituted alkynes and allenes with boranes and borocations†

James R. Lawson, Valerio Fasano, Jessica Cid, Inigo Vitorica-Yrezabal and Michael J. Ingleson*

The 1,1-carboboration of 1-Me$_3$Si-1-alkynes is the dominant reaction observed using [PhBCl(2-DMAP)][AlCl$_4$], 1, and PhBCl$_2$ electrophiles, with highly substituted vinyl pinacol boronate esters isolated post esterification. Other aryl and heteroaryl congeners of both 1 and PhBCl$_2$ have a limited scope in the 1,1-carboboration of 1-Me$_3$Si-1-alkynes, with desilylboronation more prevalent. PhBCl$_2$ converts Me$_3$Si-substituted allenes to allylboranes via a formal 1,3-carboboration with Me$_3$Si-migration. [Cl$_2$B(2-DMAP)][AlCl$_4$] reacts with a number of 1-Me$_3$Si-1-alkynes by desilylboronation, whilst with Me$_3$Si-ethyne a 1,1-borationmination reaction proceeds, which with excess boron electrophile is followed by an intermolecular desilylboronation to form a tricationic-borate. The use of excess 1-Me$_3$Si-1-propyne relative to 1 (and a thiényl congener of 1) formed 2-boradienes in low yields from the reaction with two equivalents of alkyne. Vinyl borocations ligated by 2,6-lutidine of the general formula, [[vinyl]BCl(2,6-lutidine)][AlCl$_4$] formed 1-boradienes with 1-Me$_3$Si-1-alkynes.

Introduction

The 1,1-carboboration of alkynes has received increased interest in recent years following the discovery of the 1,1-carboboration of terminal and internal alkynes with the strong electrophile RB(C$_6$F$_5$)$_2$ (R = C$_6$F$_5$, alkyl). Addition of RB(C$_6$F$_5$)$_2$ to a terminal alkyne induces a 1,2-shift of H (or a hydrocarbyl for internal alkynes) along the alkynyl backbone with subsequent migration of the R group from boron to carbon resulting in 1,1-carboboration. This reaction has been developed into a useful route to arylboranes by benzannulation, and to highly substituted vinyl boranes that are complementary to those obtained from hydroboration. 1,1-carboboration was pioneered by Wrackmeyer albeit with weaker boron electrophiles, such as trialkylboranes, for the 1,1-carboboration of activated alkynes, e.g., alkynes substituted with heavier group 14 substituents (Scheme 1, top). Wrackmeyer and co-workers reported extensively on this topic and determined the relative reactivity of a range of substituted alkynes toward BET$_3$, to be R$_3$Pb > R$_3$Sn > R$_3$Ge > R$_3$Si (TMS), with R$_3$C-substituted alkynes not amenable. These studies predominantly used trialkylboranes; in contrast, the utilisation of vinyl and aryl boranes (excluding B(C$_6$F$_5$)$_3$) for the 1,1-vinyl-boration or 1,1-aryl-boration of alkynes is rare with only limited examples reported using BPh$_3$ or PhB(C$_6$F$_5$)$_2$. One report particularly relevant to this work showed that Ph$_2$BX (X = Cl or Br) effected the 1,1-carboboration of 1-TMS-1-hexyne (Scheme 1, top). It should be noted that with [chloro]$_n$[aryl]$_{n+1}$B compounds TMS substitution appears essential for 1,1-carboboration, with PhBCl$_2$ and terminal alkynes reacting via 1,2-halo- or 1,2-carboboration instead. To the best of our knowledge the outcome from combining TMS-alkynes and (hydrocarbyl)BCl$_2$ has not been reported to date.

We envisaged combining arene borylation, or alkynne haloboration, using BCl$_3$ derived borocations (to produce arylBCl$_2$ and [vinylBCl(amino)]$^+$, respectively) with 1,1-carboboration to generate synthetically useful highly substituted vinyl (or dienyl) boronate esters after esterification (Scheme 1, bottom). This process may proceed directly from the organo-
Results and discussion

Vinylboronate ester formation

Studies commenced with the boronium cation \([\text{Ph(Cl)}\text{B}(2\text{-DMAP})][\text{AlCl}_4]\), 1.\(^{11}\) The combination of 1 and equimolar 1-TMS-1-propyne at 20 °C resulted in a slow reaction generating a new silicon containing compound \((\delta_{\text{29Si}} = -6.05)\) with minimal desilylboration observed (only a low intensity \(\text{TMSCl}\) resonance present in the \(^1\text{H}\) NMR spectra). Heating the reaction to 60 °C in \(\text{CH}_2\text{Cl}_2\) in a sealed tube for extended periods (>1 h) led to complex mixtures, however heating for 30 minutes at 60 °C led to one major new product possessing identical resonances to that observed in the 20 °C reaction, with unreacted 1 also remaining. Esterification of the reaction mixture after 30 minutes with pinacol/\(\text{Et}_3\text{N}\) led to two major boron containing products, \(\text{PhBPin}\) (derived from unreacted 1) and a new product isolable by column chromatography. NMR and mass spectroscopy confirmed this to be the product from the 1,1-carboboration of 1-TMS-1-propyne, formed as the \(E\)-isomer exclusively, 2a (Table 1). This reactivity was extended to a number of other 1-TMS-1-alkynes to yield 2b to 2e. Using these conditions \(\text{PhBPin}\) was observed as a minor product from esterification of unreacted 1 in all cases and required separation by column chromatography. The reaction of 1 with TMS-ethyne and trimethyl[3-methylbut-1-yn-1-yl]silane under analogous conditions led to complex intractable mixtures containing significant \(\text{TMSCl}\) (by \(^1\text{H}\) NMR spectroscopy).

With 1,1-carboboration observed from the combination of 1 and 1-TMS-1-alkynes the reaction of 1-TMS-1-propyne and \([\text{Cl}_2\text{B}(2\text{-DMAP})][\text{AlCl}_4]\), 3, was explored to determine if any 1,1-chloroboration occurred. Instead, this led to formation of \(\text{TMSCl}\) (by \(^1\text{H}\) and \(^{29}\text{Si}\) NMR spectroscopy) and a major new \(^{11}\text{B}\) resonance at +6.5 ppm. Esterification enabled identification of the alkynyl pinacol boronate ester confirming desilylboration (eqn (1)). Desilylboration was observed also on combination of 3 with 1-phenyl-2-TMS-acetylene and with 1-TMS-1-hexyne. Whilst in situ NMR spectra pre-esterification indicated desilylboration and alkynylboronate formation is the dominant reaction outcome, the isolated yields post pinacol esterification were consistently low due to the susceptibility of alkynyl-B species to protodeboronation.\(^{11}\)

In contrast, the combination of 3 and TMS-ethyne only formed the alkynyl-bororation as a minor species (by NMR spectroscopy). The major soluble product contained a vinylic singlet at 6.65 ppm in the \(^1\text{H}\) NMR spectrum consistent with alkynyl elemento-boration. Crystalline solid spontaneously deposited from \(\text{CH}_2\text{Cl}_2\) solutions as the reaction proceeded with a concomitant increase in the quantity of \(\text{TMSCl}\) and a decrease in the vinylic singlet (by \(^1\text{H}\) NMR spectroscopy). The amount of precipitate was increased by using an excess of 3 (5 : 4 ratio of 3 : TMS-ethyne). X-ray diffraction studies on multiple crystals consistently produced poor quality data due to low crystal quality but an unambiguous connectivity map was obtained (Fig. 1, bottom left). This revealed the compound to be the tricationic borate, 4 formed from 1,1-boroamination of TMS-ethyne and desilylboration. Due to the low data quality detailed discussion of structural metrics of 4 is not warranted.

spectroscopy is fully consistent with this formulation with NOE spectroscopy confirming the regio- and stereo-chemistry and indicating that the desilylboration of 5 to form 4 occurs with retention. The reactivity disparity between TMS-ethyne and other 1-TMS-1-alkynes studied is attributed to a less stabilised vinyl cation formed on interaction of 3 with TMS-ethyne which presumably favours rapid TMS-migration leading to 5 as the initial product and not the alkynyl-borocation from desilylboration. It is noteworthy that the reaction of [Cl₂B(2,6-lutidine)][AlCl₄], 6, a borocation where the amine does not contain a pendant nucleophile, with 1-TMS-alkynes, including TMS-ethyne, led predominantly to desilylboration in all cases.

Whilst the reactivity of 1-TMS-1-alkynes with BCl₃ proceeds by desilylboration, the analogous reactivity with PhBCl₂ has not been explored to the best of our knowledge. To determine if PhBCl₂ and 1 react comparably with 1-TMS-1-alkynes equimolar 1-TMS-1-propyne and PhBCl₂ were combined in CH₂Cl₂ at 20 °C. This resulted in a rapid reaction producing a single new product identified by multinuclear NMR spectroscopy as the product from 1,1-carboboration. Post esterification 2a was isolated in a higher yield than when using 1. A substrate scope exploration (Table 2) confirmed that the 1,1-carboboration of 1-TMS-1-alkynes with PhBCl₂ consistently proceeds in higher yield than when using 1 and does not require purification by chromatography post esterification. Furthermore, the structure of 2e was also confirmed by a single crystal X-ray diffraction study (Table 2, right). It is noteworthy that trimethyl(4-phenylbut-1-yn-1-yl)silane (entry 7) resulted in only 1,1-carboboration with no 6-endo-dig cyclisation as recently reported for related alkynes and BCl₃. The facile formation of 2a–2h by 1,1-carboboration represents an alternative to transition metal catalysed borosilylation of alkynes for accessing these versatile intermediates. Attempts to extend this reaction to 1-triisopropylsilyl-1-propyne resulted in no reaction, whilst combining PhBCl₂ and 1-(PhMe₂Si)-1-propyne resulted predominantly in desilylboration.

Table 2 1,1-Carboboration using (hetero)arylBCl₂ (right, solid state structure of 2e, hydrogens and one component of the disordered pinacol omitted for clarity)

* Isolated yield not obtained due to intractable minor contaminants of (heteroaryl)BPin.
boration products (by observation of PhMe₃SiCl by ¹H and ²⁹Si NMR spectroscopy) and multiple other currently unidentified products.

To increase the scope, variation of the aryl substituent on the borane was explored. ArylBCl₂ and heteroarylBCl₂ species are readily accessible by electrophilic arene borylation.¹⁰ Using established methodologies 2-methylthiophene, 2-methylfuran, chlorobenzene and triphenylamine were all borylated to produce the respective (hetero)arylBCl₂ compounds 7a–7d (Table 2) in good conversion as determined by multi-nuclear NMR spectroscopy.¹⁰a,b Removal of reaction solvent (CH₂Cl₂ or 1,2-Cl₂C₆H₄) and extraction of 7a–d into hexanes was sufficient to enable subsequent reaction with 1-TMS-1-propyne without any additional purification steps. This led to the formation of the desired 1,1-carboboration products which were esterified to form a single regio- and stereo-isomer of the respective vinyl pinacol boronate esters (entries 9–12). The products derived from carboboration using 7a and 7b were repeatedly contaminated with minor quantities of heteroarylBCPin (from esterification of unreacted 7a and 7b) which in our hands proved challenging to separate from 2f and 2j. The 1,1-carboboration reaction using longer times (3 h) for 7a and 1-TMS-1-propyne led to considerably more complex NMR spectra and intractable products post esterification.

Attempts to extend 1,1-carboboration using 7a–7d to other 1-TMS-1-alkynes, specifically 1-TMS-2-phenylacetylene and trimethyl(3-methylbut-1-yn-1-yl)silane, instead led to desilylboration being the dominant reaction pathway (by ¹H, ¹¹B and ²⁹Si NMR spectroscopy). To preclude the disparity between PhBCl₂ and the four (hetero)arylBCl₂ compounds 7a–d being due to any impurities in commercially sourced PhBCl₂ or impurities in (hetero)arylBCl₂ synthesised by electrophilic borylation, benzene was borylated in 1,2-Cl₂C₆H₄ using 4-N,N,N-trimethyl-aniline, BCl₃ and two equivalents of AlCl₃ to form PhBCl₂.¹⁰c This reaction mixture was dried and PhBCl₂ extracted into hexane and found to form 2f on addition of trimethyl(3-methylbut-1-yn-1-yl)silane, a substrate that 7a–d react with predominantly by desilylboration. Therefore the greater prevalence for desilylboration using 7a–d is attributed to the modified electrophilicity of the borane and the different migratory propensities of the (hetero)aryl group (relative to phenyl), indicating that the 1,1-carboboration of 1-TMS-1-alkynes using (hetero-)arylBCl₂ compounds is somewhat limited in scope.

PhBCl₂ was effective for the carboboration of silylated allenes with 8a and 8b (Scheme 2) undergoing carboboration with TMS migration producing only a single allylBCl₂ product (by multinuclear NMR spectroscopy). With no intermediates observed we attribute the reaction outcome to a 1,1-carboboration followed by a rapid intramolecular sigmatropic 1,3-boron shift to form the more thermodynamically stable less hindered allylBCl₂ species.¹⁸ This can be subsequently pinacol protected and the resultant boronate esters 9a and 9b isolated. This enables access to complementary boronate ester isomers to that produced by the hydroboration of closely related TMS-allenes where TMS migration does not occur.¹⁹

### Boradiene formation using borocations

To explore potential scope expansion further [5-methyl-2-(BCl-(2-DMAP))-thiophene][AlCl₄], 10, was synthesised by addition of 2-DMAP and AlCl₃ to 7a. The addition of 1-TMS-1-propyne to 10 resulted in a slow reaction at 20 °C that after 18 hours produced four new TMS resonances one of which was attributable to the 1,1-carboboration product (by ¹H, ¹¹B and ²⁹Si NMR spectroscopy). One of the other new compounds derived from 10/7a could be formed as a greater component of the reaction mixture when an excess of 1-TMS-1-propyne (5 equivalents) was used with heating to 60 °C for 18 h. Post esterification, isolation by column chromatography and analysis by NMR and mass spectroscopy enabled it to be identified as the 2-boradiene 11a, from reaction of 10 with two equivalents of 1-TMS-1-propyne (Scheme 3). Under identical conditions 1 also reacted with excess 1-TMS-1-propyne to produce the 2-boradiene 11b as a minor product. In contrast, heating PhBCl₂ with excess (5 equiv.) 1-TMS-1-propyne led to no observable 2-boradiene after esterification with pinacol, instead complex mixtures were produced with significant TMSCl observed in situ indicating desilylboration. Under a range of conditions 11a and 11b were formed only as minor products from 10 and 1 (with a maximum 13 and 15% isolated yield, respectively) with the 1,1-carboboration products, 2i and 2a, being the major species isolated post esterification. 2-Boradienes related to 11x have been previously synthesised by Wrackmeyer and co-workers from the reaction of BE₃ with two equivalents of 1-R₃Sn-1-alkynes.²⁰ Precise isomer assignment for 11x was based on 1D and 2D NMR spectroscopy, most notably NOESY indicated a trans-disposition of TMS and PinB moieties in the 2-bor-
Paper

adiene. This is in contrast to that in 2x suggesting that 1,1-
carboboration is not the first step in 2-boradiene formation, a
hyothesis supported by the fact that resonances for the 1,1-
carboboration products increase in intensity as the reaction pro-
gresses, suggesting it is not an intermediate in diene formation.
Instead we propose that 1-TMS-1-propyne is activated to an
intermolecular attack by a second equivalent of alkyne by inter-
action with the borocation and this ultimately leads to the
observed 2-boradiene structures. Related borane activation of
alkynes towards external π nucleophiles have been reported pre-
viously,20,21 As repeated attempts to crystallise 11a and 11b
failed in our hands to support the proposed diene structure, particularly correlating the structure with the multiple NOE
interactions observed, the structure of 11b was optimised at the
M06-2X/6-311G(d,p)(PCM:DCM) level. This revealed that steric
bulk forces a significant dihedral angle in the diene (C=C-
C=C = 60.24°) and thus short distances (<4 Å) were observed in
the calculated structure for all the observed NOE interactions,
supporting this isomer assignment. Attempts to form other
2-boradienes using different (hetero)arylboronium cations or
different TMS-alkynes all led to complex mixtures and lower
conversions than that observed for 11a and 11b.

Subsequently, the one pot, two step reaction of 3 with termi-
nal alkynes (proceeding by 1,2-haloboration as previously
reported to form 12x, eqn (2))11 followed by addition of
1-TMS-1-propyne was explored as an alternative route to 2-bor-
diienes. The addition of 1-TMS-1-propyne to 12a or 12b gave
no reaction (by NMR spectroscopy) at room temperature after
18 hours. When the reaction mixture was heated to 60 °C for
1 h multiple new species were observed in the 1H NMR spec-
trum, including [(2-DMAP)H]+, as well as four new 29Si reso-
nances (one corresponding to TMSCl) and new 11B resonances
at +55 and +66 ppm. Esterification and attempts to purify the
resultant complex mixture failed to deliver pure products in
our hands. A more electrophilic vinyl-borocation was targeted
to enable room temperature reactivity with 1-TMS-1-alkynes
and potentially avoid the complex mixtures observed with 12x
at 60 °C. Thus the reactivity of [(vinyl)BCl(2,6-lutidine)]+ cations,
made via haloboration of alkynes with 6, with 1-TMS-1-alkynes was explored.

In a one pot two step reaction 6 was used to separately halo-
borate 1Bu-acetylene and phenylacetylene followed by addition
of one equivalent 1-TMS-1-propyne, which did not lead to any
significant TMSCl formation at short reactions times (<1 h by
NMR spectroscopy) in each case. The initial haloboration step is
rapid (complete in <5 minutes with both terminal alkynes
whilst the subsequent reaction with 1-TMS-1-propyne is slower
it did proceed to form carboboration products (Scheme 4).
Running the reaction for longer times at 20 °C (≥2 h) resulted

in significant TMSCl formation, whilst attempts to use greater
equivalents of 1-TMS-1-propyne also led to more TMSCl for-
mation; thus optimized conditions of 1.2 equivalents of
1-TMS-1-propyne and a 1 h reaction duration were found to
minimise the amount of unreacted haloboration compounds
(12a–b) remaining and TMSCl formation. Post esterification
the boradiene products 13a–b could be separated from the
vinyl-pinacol boronate esters (formed from esterification of
unreacted 12a–b) with NMR spectroscopy consistent with a
1-boradiene formation from a 1,2-carboboration
reaction (Scheme 4). Notably a JHH coupling of 1 Hz is
observed between the methyl and the vinyl-H in both 13a and
13b confirming the connectivity as this coupling would not be
observed in the 1,1-carboboration products. Whilst 1,2-carbo-
boration is less documented that 1,1-carboboration several
recent examples have been reported,22 including using boro-
cations,13,23 The diene structure (Scheme 4) expected from 1,2-
carboboration was confirmed by NOESY and in the absence of
crystalline material (which was unobtainable in our hands)
supported by optimising the structure of 13b at the M06-2X/
6-311G(d,p)(PCM:DCM) level. This indicated that 13b is a non-
planar diene (C=C-C=C = 39.93°) and that all observed NOE
interactions correspond to calculated H–H distances of <4 Å.
We attribute the reactivity disparity between 2-DMAP (2-bora-
diienes) and 2,6-lutidine (1-boradienes) borocations to the
greater steric demand of 2,6-lutidine which disfavours for-
mation of a more sterically hindered 2-boradiene. This is con-
sistent with calculations on a model complex (at the M06-2X/
6-311G(d,p)(PCM:DCM) level) which show that the 2-boradiene
B is 5 kcal mol−1 higher in energy than the 1-boradiene isomer
A (Scheme 4). Furthermore, in contrast to 1,1-carboboration
reactions with BET3,24 the 1,2-vinylboronation to form A is unlikely
to be reversible at 20 °C. This is indicated by the conversion of
the model compound 12Me (where R = Me) to A being

Scheme 4 1-Boradiene formation by haloboration and 1,2-carbobora-
tion. Electronic energies (Gibbs free energies at 293 K) shown in kcalmol−1 for the model system where R = Me (all energies relative to
12Me and 1-TMS-1-propyne at infinite distance).
found to be exergonic by 7.7 kcal mol\(^{-1}\), thus the barrier to the reverse process (retro-vinylboration) will be significantly higher than that for the forward reaction (which requires at least 1 h for significant conversion).

As bora-dienes are useful species for a range of subsequent synthetic transformations,\(^2\) the broader applicability of this reaction was explored initially looking at other terminal alkynes. 12c–12e were all readily produced by haloboration with 6 and underwent 1,2-carboboration to form 13c–13e, however the isolated yields of 13e were poor to moderate (23–59%), whilst 13d and 13e could not be separated from reaction by-products. The propensity of other 1-TMS-1-alkynes to undergo 1,2-carboboration, specifically 1-TMS-2-phenylacetylene and 1-TMS-1-hexyne, were investigated using 12a, however the reaction was slower (by \textit{in situ} NMR spectroscopy and resulted in lower conversions to the desired boradiene and more unidentified by-products. Finally, the use of an internal alkyn, 3-hexyne, was investigated, which as previously reported underwent facile haloboration with 6,\(^11\) but subsequent reaction with 1-TMS-1-propyne resulted in a low conversion to the 1-boradiene product which was isolated as the pinacol boronate ester, 13f in only 10% yield. The low conversions with more substituted systems is presumably due to the increased steric crowding resulting in the slower formation of the 1,2-carboboration products and thus increased formation of by-products derived from desilylboration.

**Conclusions**

The carboboration of 1-TMS-1-alkynes with aryl dichloroboran and aryl-substituted and vinyl-substituted borocations has been demonstrated to yield highly substituted vinyl and dienyl boronate esters post esterification. However, due to carboboration occurring in competition with desilylboration and diene formation, coupled with further reactions proceeding subsequent to the initial carboboration (e.g., desilylboration), complex mixtures are often produced that limit the overall utility of this reaction. Variation in borane and borocation structure is therefore essential to preclude desilylboration to generate more general and higher yielding 1-TMS-1-alkyne carboboration protocols.

**Experimental**

**General considerations**

All manipulations of air and moisture sensitive species were performed under an atmosphere of argon or nitrogen using standard Schlenk and glovebox techniques. Glassware was dried in a hot oven overnight and heated under vacuum before use. Hexane, \textit{ortho}-dichlorobenzene, d\textsubscript{1}-chloroform, d\textsubscript{2}-dichloromethane, 2,6-lutidine, Et\textsubscript{3}N and were dried over calcium hydride and distilled under vacuum. Pentane and dichloromethane were dried by passing through an alumina drying column incorporated into an MBraun SPS800 solvent purification system. All solvents were degassed and stored over molecular sieves (3 Å) under an inert atmosphere. Compounds 1 and 3 were synthesised according to the published procedures.\(^1\) All other materials were purchased from commercial vendors and used as received. NMR spectra were recorded with a Bruker AV-400 spectrometer (400 MHz \(\text{H}\); 100 MHz \(\text{C}\); 128 MHz \(\text{B}\); 376.50 MHz \(\text{F}\); 104.3 MHz \(\text{Al}\); 79.5 MHz \(\text{Si}\)). 1H NMR chemical shifts are reported in ppm relative to protio impurities in the deuterated solvents and 13C NMR using the solvent resonances unless otherwise stated. 13B NMR spectra were referenced to external BF\textsubscript{3} : Et\textsubscript{2}O, 19F to Cl\textsubscript{2}CF\textsubscript{2}, 27Al to Al(NO\textsubscript{3})\textsubscript{3} in D\textsubscript{2}O (Al(D\textsubscript{2}O)\textsubscript{3}\textsuperscript{3+}), \textsuperscript{29}Si to Si(\text{CH})\textsubscript{3}. Resonances for the carbon directly bonded to boron are not observed in the \(1^{13}\)C(\text{H}) NMR spectra due to quadrupolar effects. GC-MS analysis was performed on an Agilent Technologies 7890A GC system equipped with an Agilent Technologies 5975C inert XL EI/CI MSD with triple axis detector. The column employed was an Agilent J&W HP-5 ms ((5%-phenyl)-methylpolysiloxane) of dimensions: length, 30 m; internal diameter, 0.250 mm; film, 0.25 \textmu m. Mass spectra were recorded on a Waters QTOF mass spectrometer. X-ray data for compounds 2e and 4 was collected at a temperature of 150 K using Mo-K\textsubscript{α} radiation on an Agilent Supernova, equipped with an Oxford Cryosystems Cobra nitrogen flow gas system. Elemental analysis of air sensitive compounds was performed by London Metropolitan University service. Repeated attempts to obtain satisfactory elemental analyses for a range of the pinacol boronate esters repeatedly gave results with low carbon content, even when using V\textsubscript{2}O\textsubscript{5} as an additional oxidant.

**General procedures for 1,1-carboboration reactions**

With [PhBCl(2-DMAP)][AlCl\textsubscript{4}] (Route 1). To a suspension of [PhBCl(2-DMAP)][AlCl\textsubscript{4}] (50 mg, 0.12 mmol, 1 eq.) in DCM (0.5 ml) in a J. Youngs NMR tube was added 1-TMS-1-alkyne (0.12 mmol, 1 eq.). This was sealed and the mixture heated for 30 minutes after which time an excess of triethylamine (0.1 ml) and pinacol (30 mg, 0.24 mmol, 2 eq.) were added and the solvent was removed under reduced pressure to leave an oil. Pentane was used to extract the product, which was passed through a 1 inch plug of silica to remove pinacol impurities. Column chromatography (DCM : hexane, 1 : 1) was used to separate the desired product from the by-products.

With PhBCl\textsubscript{2} (Route 2). To a solution of PhBCl\textsubscript{2} (200 \mu l, 1.5 mmol, 1 eq.) in DCM (5 ml) in a Schlenk was added 1-TMS-1-alkyne (1.5 mmol, 1 eq.). After \(x\) hours an excess of triethylamine (0.5 ml) and pinacol (350 mg, 3.0 mmol, 2 eq.) were added, and the solvent was removed under reduced pressure to leave an oil. Filtration through a 1 inch plug of silica afforded the product in good purity without column chromatography.

(\textit{E})-1-Phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)prop-1-en-2-yl trimethylsilane (2a). The product was isolated as a yellow oil (Route 1: 24 mg, 63%). (Route 2: 424 mg, 88%).

\(^1\)H NMR (400 MHz, CDCl\textsubscript{3}) \(\delta\) 7.30 \(t\), 2H, \(J(H,H) = 7.2\) Hz), 7.18 \(t\), 1H, \(J(H,H) = 7.2\) Hz), 7.06 \(d\), 2H, \(J(H,H) = 7.2\) Hz),
1.68 (s, 3H), 1.23 (s, 12H), 0.23 (s, 9H); 13C{1H} NMR (100.06 MHz, CDCl₃) δ 150.92, 143.54, 128.42, 127.86, 125.55, 83.50, 25.05, 20.58, 0.00; 11B NMR (128.4 MHz, CDCl₃); δ 30.2; 29Si NMR (79.5 MHz, CDCl₃); δ −4.22 ppm. MS: (GC, M + Na⁺/m/z) 367.4.

(E)-(1,4-Diphenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-but-1-en-2-yl)trimethylsilane (2g). Trimethyl(4-phenylbut-1-yl)silane (45 µL, 0.20 mmol, 1.0 eq.) was dissolved in DCM (0.6 ml) in a J. Youngs tube, PhBCl₂ (29 µL, 0.22 mmol, 1.1 eq.) was then added and the reaction sealed and rotated. After 1 h, a cooled solution of pinacol (26 mg, 0.22 mmol, 1.1 eq.) and excess of triethylamine were added to the reaction mixture. The reaction mixture was then concentrated under reduced pressure, the resultant crude was dissolved in pentane, filtered and concentrated. The residue was then purified by flash chromatography (petroleum ether: DCM 70:30), affording 2g (30 mg, 37%, as a white solid.

1H NMR (400 MHz, CDCl₃); δ 7.31 (t, 7.6 Hz, 2H), 7.22 (d, J = 7.34 Hz, 1H), 7.13–7.18 (m, 2H), 7.07–7.12 (m, 3H), 6.85 (d, J = 7.0 Hz, 2H), 2.40–2.47 (m, 2H), 2.28–2.36 (m, 2H), 1.22 (s, 12H), 0.31 (s, 9H); 13C{1H} NMR (100.06 MHz, CDCl₃); 154.4, 143.2, 142.4, 128.1, 128.0, 127.9, 127.8, 125.6, 125.5, 83.5, 36.6, 36.2, 24.9, 0.7; 11B NMR (128 MHz, CDCl₃); δ 30.9 (s) ppm; 29Si NMR (79.5 MHz, CDCl₃); δ −4.4 (s) ppm; MS (GC, [M − CH₃]⁺, m/z) 319.3; accurate mass: ([M + H⁺] 407.2583).

(2)-Trimethyl-2-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)vinylsilane (2h). Trimethylsilylacetylene (48 µL, 0.33 mmol, 1.0 eq.) was dissolved in DCM in a J. Youngs tube, PhBCl₂ (49 µL, 0.37 mmol, 1.1 eq.) was then added and the tube sealed. After 1 h at 60 °C a cooled solution of pinacol (44 mg, 0.37 mmol, 1.1 eq.) and excess of triethylamine were added to the reaction mixture. The reaction mixture was then concentrated under reduced pressure and the crude was dissolved in pentane, filtered and concentrated. The residue was then purified by flash chromatography (petroleum ether: DCM 70:30), affording 2h (30 mg, 30%) as a colourless oil.

1H NMR (400 MHz, CDCl₃); δ 7.41 (d, J = 8.1 Hz, 2H), 7.30 (t, J = 7.8 Hz, 2H), 7.21–7.26 (m, 1H), 6.74 (s, 1H), 1.34 (s, 12H), 0.23 (s, 9H); 13C{1H} NMR (100 MHz, CDCl₃); 150.6, 145.5, 128.0, 126.9, 126.7, 83.8, 25.1, 0.3; 11B NMR (128 MHz, CDCl₃); δ 30.2 (s) ppm; 29Si NMR (79 MHz, CDCl₃); δ −9.2 (s) ppm; MS (GC, [M − CH₃]⁺, m/z) 287.1; accurate mass: ([M − CH₃]⁺ 287.1635).

(E)-(1-(5-Methylthiophen-2-yl)-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)prop-1-en-2-yl)trimethylsilane (2i). [BCl₂(2-DMAP)]-[AlCl₄] (100 mg, 2.7 mmol, 1 eq.) was combined with 2-methylthiophene (26 µL, 2.7 mmol, 1 eq.) in DCM (0.5 ml) in a J. Youngs NMR tube which was then sealed and heated at 60 °C for 1 hour. NMR spectroscopy confirmed formation of 2-methylthiophene·BCl₂ which was extracted into hexane (10 ml). To this, 1TMS-1-propyne (80 µL, 5.4 mmol, 2 eq.) was added with the reaction mixture turning deep orange. The reaction mixture was esterified after 1 hour by addition of excess Et₃N (0.1 ml) and pinacol (96 µL, 3 eq.). The crude product was extracted into pentane (20 ml) and filtered through a 1 inch plug of silica affording the desired product contaminated with 2-methyl-5-BPin-thiophene. The data below are for 2i with resonances for the minor product omitted.
1H NMR (400 MHz, CDCl3) δ 6.63 (m, 1H), 6.57 (d, 1H, J(H,H) = 7.1 Hz), 2.46 (s, 3H), 1.93 (s, 3H), 1.29 (s, 12H), 0.22 (s, 9H); 13C{1H} NMR (100.06 MHz, CDCl3) δ 148.27, 139.11, 135.82, 126.00, 122.91, 83.22, 25.01, 20.37, 15.86, 0.02 ppm; 11B NMR (128.4 MHz, CDCl3): δ 30.0; 29Si NMR (79.5 MHz, CDCl3) δ −3.92 ppm. MS (GC, M−, m/z): 336.4.

(E)-(1-(5-Methylfuran-2-yl)-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)prop-1-en-2-yl)trimethylsilane (2j). [BCl2(2-DMAP)][AlCl4] (100 mg, 2.7 mmol, 1 eq.) was combined with 2-methylfur-2-en-2-yl)trimethylsilane (25 µl, 2.7 mmol, 1 eq.) and filtered through a 1 inch plug of silica a (78 mg, 3 eq.). The crude product was extracted into pentane and filtered through a 1 inch plug of silica affording the product. (85 mg, 61%).

1H NMR (400 MHz, CDCl3) δ 7.03 (d, 2H, J(H,H) = 8.2 Hz), 6.75 (d, 2H, J(H,H) = 8.2 Hz), 1.44 (s, 3H), 1.00 (s, 12H), 0.00 (s, 9H); 13C{1H} NMR (100.06 MHz, CDCl3) δ 152.57, 136.11, 131.30, 129.82, 128.03, 83.59, 24.99, 20.77, 0.00; 11B NMR (128.4 MHz, CDCl3): δ 30.0; 29Si NMR (79.5 MHz, CDCl3) δ −4.04 ppm. MS: (GC, M−, m/z): 350.1.

Compound 4. A 5:4 ratio of [BCl2(2-DMAP)][AlCl4] (100 mg, 0.27 mmol, 1 eq.) in triethylsilacycletene (31 µl, 0.22 mmol, 4 eq.) was dissolved in CH2Cl2 in a J. Young’s NMR tube. On standing a crystalline solid precipitated out of solution. Removal of the solvent and washing with pentane allowed isolation of the crystals 21 mg, 27% (based on boron content).

1H NMR (400 MHz, CD2CN, −40 °C): δ 8.91 (d, 1H), 8.71 (t, 1H), 8.28 (d, 1H), 8.16 (t, 1H), 7.89 (s, 1H), 3.78 (s, 3H), 3.45 (s, 3H); 13C{1H} NMR (128.4 MHz, CD2CN): δ 3.90, −15.44; 11B NMR (100.6 MHz, CD2CN): δ 154.09, 150.15, 143.80, 130.47, 119.85 ppm. Expected (%) for C8H16Al2B2N2Cl2O = C = 30.18 H = 3.10 N = 7.82. Found (% C = 29.94, H = 2.97, N = 7.65).

Compound 5. To a 1:1 suspension of [BCl2(2-DMAP)][AlCl4] (100 mg, 0.27 mmol, 1 eq.) in CH2Cl2 in a J. Young’s NMR tube was added trimethylsilacycletene (38 µl, 0.27 mmol, 1 eq.) and was sealed and rotated at room temperature for 18 hours. The solvent was removed under reduced pressure, and the product redisolved in DCM.

1H NMR (400 MHz, CD2Cl2) δ 8.99 (d, 1H), 8.88 (t, 1H), 8.56 (d, 1H), 8.25 (t, 1H), 6.65 (s, 1H), 3.80 (s, 3H), 3.08 (s, 9H); 11B NMR (128.4 MHz, CD2Cl2): δ 2.5 (s); 29Si NMR (79.5 MHz, CD2Cl2) δ −3.6 ppm. Due to difficulties in purifying this compound, the 13C NMR spectra were complicated by numerous minor species. Accurate elemental analysis could not be obtained due to the impure nature of the material from each attempt to isolate this product.

(E)-(3-phenyl-(1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)but-2-en-2-yl)trimethylsilane (9a). 3-(Trimethylsilyl)-1,2-butadiene (25 µL, 0.15 mmol, 1.0 eq.) was dissolved in DCM in a J. Young’s tube and PhBCl2 (22 µL, 0.16 mmol, 1.1 eq.) was added. After 1 h a cooled solution of pinacol (19 mg, 0.16 mmol, 1.1 eq.) and excess triethylamine were added to the reaction mixture. The reaction mixture was then dried under reduced pressure and the crude was dissolved in pentane, filtered and concentrated. The residue was purified by flash chromatography (petroleum ether: DCM 60:40), affording 9a (21 mg, 43%) as a white solid.

1H NMR (400 MHz, CD2Cl2) δ 7.29 (t, J = 7.2 Hz, 2H), 7.19 (t, J = 7.4 Hz, 1H), 7.14 (d, J = 7.0 Hz, 2H), 2.10 (s, 3H), 1.57 (s, 2H), 1.23 (s, 12H), 0.23 (s, 9H); 13C{1H} NMR (100 MHz, CD2Cl2): δ 146.0, 145.1, 131.3, 128.0, 127.6, 125.9, 82.9, 25.3, 24.8, 0.4; 11B NMR (128.4 MHz, CD2Cl2): δ 33.7 (s) ppm; 29Si NMR (79.5 MHz, CD2Cl2): δ −5.8 (s) ppm. MS: (GC, M−, m/z): 330.2, accurate mass: [M]+ 330.2181.

(E)-(2-Phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)pent-2-en-3-yl)trimethylsilane (9b). 2-(Trimethylsilyl)-2,3-pentadiene (25 µL, 0.13 mmol, 1.0 eq.) was dissolved in DCM in a
J. Youngs tube and PhBCl$_2$ (20 μL, 0.14 mmol, 1.1 eq.) was added. The reaction mixture was heated at 60 °C and after 24 h a cooled solution of pinacol (17 mg, 0.14 mmol, 1.1 eq.) and excess triethylamine were added to the reaction mixture. The reaction mixture was then dried under reduced pressure and the crude was dissolved in pentane, filtered and concentrated. The residue was purified by flash chromatography (petroleum ether: DCM 60 : 40), affording 9b (10 mg, 22%) as a colourless oil.

$^1$H NMR (400 MHz, CDCl$_3$) 6 7.29 (t, $\delta=7.2$ Hz, 2H), 7.20 (t, $\delta=7.3$ Hz, 1H), 7.14 (d, $\delta=6.9$ Hz, 2H), 2.08 (s, 3H), 2.04 (q, $\delta=7.5$ Hz, 1H), 1.22 (s, 12H), 0.92 (d, $\delta=7.5$ Hz, 3H), 0.26 (s, 9H); $^{13}$C{1H} NMR (100 MHz, CDCl$_3$): δ 146.4, 145.8, 138.4, 128.0, 127.8, 125.8, 82.9, 25.8, 25.3, 24.7, 16.3, 1.6; $^{11}$B NMR (128 MHz, CDCl$_3$): δ 34.5 (s) ppm; $^{29}$Si NMR (79 MHz, CDCl$_3$): δ −6.6 (s) ppm. MS: [M]+ 344.2337.

**General procedure for vinylboronation with 6**

LutBCl$_2$ (50 mg, 0.22 mmol) was suspended in anhydrous CH$_2$Cl$_2$ (5 ml) in a J. Young’s NMR tube and AlCl$_3$ (30 mg, 0.22 mmol) added causing dissolution to form a yellow solution. To this the appropriate alkyne (0.22 mmol) was added and the tube resealed and rotated for a further 45 minutes. Then the solution was esterified with excess triethylamine (0.5 ml) and pinacol (2 eq.). The solvent was removed under reduced pressure, leaving a yellow oil. Hexane (30 ml) was used to extract the product, which was filtered. This left a mixture of the desired diene and the haloboration derived vinyl by-product used to determine NMR conversion before purification by column chromatography.

$$((2Z,4Z)-3-(5-Methylthiophen-2-yl)-4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexa-2,4-diene-2,5-diyli)bis(trimethylsilane)$$

(11a). To a suspension of [Cl$_2$B(2-DMAP)][AlCl$_4$] (50 mg, 0.14 mmol, 1 eq.) in DCM (0.5 ml) in a J. Youngs NMR tube was added 1-TMS-1-propyne (90 μL, 0.14 mmol, 1 eq.) in DCM (0.5 ml) in a J. Youngs NMR tube was added 1-TMS-1-propyne (90 μL, 0.14 mmol, 1 eq.) and the tube was sealed and heated to 60 °C. After 18 h an excess of triethylamine (0.1 ml) and pinacol (30 mg, 0.24 mmol, 2 eq.) were added and the solvent was removed under reduced pressure. Pentane (20 ml) was used to extract the product which was then passed through a 1 inch plug of silica. Column chromatography (DCM: hexane, 1:1) was used to separate the desired diene from the 1,1-carboboration product. The product was isolated as a yellow oil (8 mg, 22%).

$^1$H NMR (400 MHz, CDCl$_3$) δ 6.59 (d, 1H, $\delta= 3.5$ Hz), 6.51 (m, 1H), 2.42 (s, 3H), 1.96 (s, 3H), 1.81 (s, 3H), 1.20 (s, 6H), 1.17 (s, 6H), 0.08 (s, 9H), −0.03 (s, 9H); $^{13}$C{1H} NMR (100.06 MHz, CDCl$_3$) δ 147.42, 146.02, 144.67, 139.85, 135.77, 126.83, 125.69, 83.06, 24.65, 24.59, 22.23, 20.49, 15.44, −0.13, −0.54; $^{11}$B NMR (128 MHz, CDCl$_3$): δ 30.0; $^{29}$Si NMR (79.5 MHz, CDCl$_3$) δ −5.98 ppm. MS: [GC, M+]+ 362.7. 

$$((2Z,4Z)-3-(5-Methylthiophen-2-yl)-4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexa-2,4-diene-2,5-diyli)bis(trimethylsilane)$$

(11b). To a suspension of [PhBCl(2-DMAP)][AlCl$_4$] (50 mg, 0.12 mmol, 1 eq.) in DCM (0.5 ml) in a J. Youngs NMR tube and PhBCl$_2$ (20 μL, 0.12 mmol, 1 eq.) was added and the tube was sealed and then heated at 60 °C. After 18 h an excess of triethylamine (0.1 ml) and pinacol (30 mg, 0.24 mmol, 2 eq.) were added and the solvent was removed under reduced pressure. Pentane (20 ml) was used to extract the product which was then passed through a 1 inch plug of silica. Column chromatography (DCM: hexane, 1:1) was used to separate the desired diene from the 1,1-carboboration product. This left a mixture of the desired diene and the haloboration derived vinyl by-product used to determine NMR conversion before purification by column chromatography.

$$((2E,4E)-4-Chloro-2,5,5-trimethyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)hexa-1,3-dien-1-yl)trimethylsilane$$

(13a). This crude product (65% yield by NMR spectroscopy) was purified with column chromatography using 2:1 hexane: DCM eluent and isolated as a yellow oil (18 mg, 23%).

$^1$H NMR (400 MHz, CDCl$_3$) δ 6.24 (q, 1H, $\delta= 1$ Hz), 1.78 (d, 3H, $\delta= 1$ Hz), 1.29 (s, 12H), 1.22 (s, 9H), 0.19 (s, 9H); $^{13}$C{1H} NMR (100.06 MHz, CDCl$_3$) δ 154.05, 144.78, 123.72, 83.26, 38.72, 28.94, 25.36, 20.73, 0.28; $^{11}$B NMR (128.4 MHz, CDCl$_3$): δ 29.41; $^{29}$Si NMR (79.5 MHz, CDCl$_3$) δ −46.44 ppm. MS: [GC, M+]+ 356.3 g mol$^{-1}$.

$$((2E,4E)-4-Chloro-2-methyl-4-phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)buta-1,3-dien-1-yl)trimethylsilane$$

(13b). This crude product (71% conversion by NMR spectroscopy) was purified with column chromatography using 2:1 hexane: DCM eluent and isolated as a yellow oil (49 mg, 59%).

$^1$H NMR (400 MHz, CDCl$_3$) δ 7.69 (m, 2H), 7.38–7.30 (m, 3H), 6.94 (q, 1H, $\delta= 1$ Hz), 1.91 (d, 3H, $\delta= 1$ Hz), 1.33 (s, 12H), 0.25 (s, 9H); $^{13}$C{1H} NMR (100.06 MHz, CDCl$_3$) δ 155.01, 147.37, 136.44, 129.00, 128.31, 127.32, 120.10, 100.04, 74.25, 22.87, 0.41; $^{11}$B NMR (128.4 MHz, CDCl$_3$): δ 29.16; $^{29}$Si NMR (79.5 MHz, CDCl$_3$) δ −4.18 ppm. MS: [GC, M+]+ 376.2.

$$((2E,4E)-4-Chloro-2-methyl-5-phenyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)penta-1,3-dien-1-yl)trimethylsilane$$

(13c). This crude product (70% conversion by NMR spectroscopy) was purified with column chromatography using 2:1 hexane: DCM eluent and isolated as a yellow oil (27 mg, 31%).

$^1$H NMR (400 MHz, CDCl$_3$) δ 7.63–7.23 (m, 5H), 6.37 (q, 1H, $\delta= 1$ Hz), 3.74 (s, 2H), 1.84 (d, 3H, $\delta= 1$ Hz), 1.30 (s, 12H), 0.20 (s, 9H); $^{13}$C{1H} NMR (100.06 MHz, CDCl$_3$) δ 156.72, 138.00, 132.80, 129.37, 128.28, 128.28, 128.56, 83.41, 45.64, 25.32, 21.43, 0.36; $^{11}$B NMR (128.4 MHz, CDCl$_3$):
Dalton Transactions

δ 29.5 ppm; \textsuperscript{29}Si NMR (79.5 MHz, CDCl\textsubscript{3}) δ −4.40 ppm. MS: (GC, M\textsuperscript{+}, m/z) 390.2.

(1E,3E)-4-Chloro-2-methyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)-4-(p-tolyl)buta-1,3-dien-1-yl)trimethylsilane (13d). Attempts at purifying the crude product (70% conversion by NMR spectroscopy) by column chromatography failed. NMR data are given with the vinylboronate ester resonances omitted.

\textsuperscript{2}H NMR (400 MHz, CDCl\textsubscript{3}) δ 7.42–7.38 (m, 2H), 7.01–6.99 (m, 2H), 6.72 (m, 1H), 1.72 (m, 3H), 1.21 (s, 3H), 1.15 (s, 12H), 0.07 (s, 9H); \textsuperscript{11}B NMR (128.4 MHz, CDCl\textsubscript{3}) δ 29.5; \textsuperscript{29}Si NMR (79.5 MHz, CDCl\textsubscript{3}) δ −4.24 ppm.

(1E,3E)-4-Chloro-4-(methoxyphenyl)-2-methyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)buta-1,3-dien-1-yl)trimethylsilane (13e). Attempts at purifying the crude product (67% conversion by NMR spectroscopy) by column chromatography failed. NMR data are given with the vinylboronate ester resonances omitted.

\textsuperscript{2}H NMR (400 MHz, CDCl\textsubscript{3}) δ 7.61–7.59 (m, 2H), 6.89–6.87 (m, 2H), 6.81 (m, 1H), 3.83 (s, 3H), 1.88 (m, 3H), 1.32 (s, 12H), 0.23 (s, 9H); \textsuperscript{11}B NMR (128.4 MHz, CDCl\textsubscript{3}) δ 30.0; \textsuperscript{29}Si NMR (79.5 MHz, CDCl\textsubscript{3}) δ −4.28 ppm.
