Two series of ferrocenyl- and aryl-derived cyclopalladated organosilane thiosemicarbazone complexes were synthesised *via* C–H bond activation. Selected compounds were evaluated for *in vitro* antiplasmodial activity against the chloroquine-sensitive (NF54) and chloroquine-resistant (Dd2) strains of the human malaria parasite *Plasmodium falciparum*. Cyclopalladation of the thiosemicarbazones resulted in antiplasmodial activities in the low micromolar range.

Introduction

Malaria continues to be one of the most widespread parasitic infectious diseases in the world today. An estimated 198 million cases of malaria were reported in 2013, with a large percentage of people who die from the disease made up of children under the age of five.¹ Most of the malaria infection cases are known to occur in sub-Saharan Africa.

Chloroquine (CQ), a quinoline-based compound, was the most successful clinical drug of choice for the treatment of malaria, but the emergence of resistant strains of the causative agent *Plasmodium falciparum* has rendered CQ useless in many parts of the world. The current last line of defence against resistant parasites is the artemisinin combination therapy (ACT) regimen. Unfortunately, the recent emergence of resistance to this regimen in parts of Asia, warrants the search for novel drug regimens.^{2,3}

Thiosemicarbazones (TSCs) are thioureas known to display a large spectrum of pharmacological properties, particularly as antiparasitic agents, and are therefore exploitable in the development of new chemotherapeutics.^{4–9} The precise antiplasmodial mode of action of TSCs is currently unknown. Thiosemicarbazones are proposed to inhibit cysteine proteases, which are integral in several parasite functions.¹⁰

The use of transition metals in drug discovery has become a popular strategy, particularly where metals have been combined with compounds of known therapeutic value in an attempt to combat drug resistance. This has been exemplified by the bioorganometallic compound ferroquine, with ferrocene incorporated into the lateral side-chain of chloroquine, allowing for greater transmembrane interactions owing to its more lipophilic nature.^{11–13} The most notable pioneering work is the rhodium(i)-chloroquine derivatives synthesised by Sánchez-Delgado and co-workers.¹⁴ These derivatives showed a reduction in parasitaemia *in vivo* to a greater extent than that of chloroquine, endorsing the use of metal-based compounds in malaria chemotherapy. For further reports on metallo-antimalarials in the literature, several excellent recent reviews abound.^{12,13,15–17}

The application of platinum group metals (PGMs) as chemotherapeutic agents has therefore emerged as a viable area of research. There are not many examples of transition metal complexes of TSCs reported with antiplasmodial activity. Within our research group, we have evaluated transition metals from the platinum group series as antiplasmodials.^{4,18–21} We have explored the chemistry associated with *N,S*- and *O,N,S*-chelated TSC systems, and to a limited extent the preparation of *C,N,S*-chelated TSC cyclometallated complexes. Cyclometallated complexes can be prepared *via* the oxidative addition of aryl halides; however, within our group cyclometallated complexes prepared *via* C–H activation is of interest.^{22,23} In particular, the biological evaluation of these types of cyclopalladated complexes especially, is relatively rare.

A recent strategy that we have pursued in the search for novel antimalarial metal-based drug leads is the incorporation of organosilane moieties into our structures.^{24–26} This strategy has been used with great success to enhance biological activity

and reduce toxicity in an effort to increase the therapeutic value of drugs. Organosilane moieties also increase the lipophilicity of a drug molecule which in turn provides several physiological benefits, including improved tissue and cell penetration, which may result in an increase in permeability and ultimately bioavailability.^{27–32}

As a follow-up to our recent studies,^{24–26} we were prompted to explore the effect of introducing silicon into cyclopalladated thiosemicarbazone complexes, in an attempt to identify potential new antimalarial compounds. To the best of our knowledge, there are no reports on the use of silicon-containing thiosemicarbazone cyclopalladated complexes in the field of bioorganometallic antiplasmodial research.

Herein, we report the synthesis and characterisation of a series of new cyclopalladated silicon-containing compounds based on a thiosemicarbazone scaffold along with their *in vitro* antiplasmodial activities.

Results and discussion

Synthesis and characterisation

The ferrocenyl- and aryl-derived TSCs (**1**–**3**) containing either a methylene (**1a**–**3a**) or propyl (**1b**–**3b**) spacer were prepared by refluxing the corresponding Schiff-base dithiocarbamate and the appropriate amine (Scheme 1). This occurred *via* a nucleophilic substitution of the methanethiol group of the dithiocarbamates with the amine. The dithiocarbamates and the TSCs (**1a**–**3a**) are known compounds which were prepared following published methods.^{26,33,34} The dithiocarbamates were prepared *via* the Schiff-base condensation of methyl hydrazine-carbodithioate³⁵ with either acetylferrocene or 3,4-dichloroacetophenone.^{33,34} The cyclopalladated complexes (**4**–**6**) were prepared *via* C–H activation of the cyclopentadienyl or aryl rings of the ferrocenyl- and aryl-derived TSCs, respectively, when reacted with the palladium precursor *cis*-[PdCl₂(PTA)₂] in the presence of triethylamine as the base (Scheme 1). These palladacycles are formed through an electrophilic substitution reaction. The palladium(II) metal centre inserts into the C–H bond to form a Pd–C bond with the *ortho* carbon atom of the ferrocenyl or aryl ring. The triethylamine facilitates the deprotonation of the ring. The incorporation of 1,3,5-triaza-7-phosphaadamantane (PTA) into complexes of biological interest has increased due to the improved solubility of PTA-containing complexes. Within the context of malaria, PTA-containing complexes have exhibited promising *in vitro* activities against *P. falciparum*.^{4,20,36–38}

Synthesis of the ferrocenyl- and aryl-derived TSCs was confirmed by the absence of the methanethiol (SCH₃) protons and the appearance of signals for the newly incorporated amine in the ¹H NMR spectra. The absence of a signal for a proton of the substituted cyclopentadienyl ring (**4**) or the C-6 position on the aryl ring (**5**; **6**) confirmed the synthesis of the cyclopalladated complexes. Formation of the palladacycle was further confirmed by the absence of the hydrazinic proton, which suggests that the TSC chelates in the thiolate form. Further-

Scheme 1 Reagents and conditions: (i) EtOH, reflux [7 h (**1b**); 24 h (**2b**, **3b**)]; (ii) *cis*-[PdCl₂(PTA)₂], Et₃N, EtOH, reflux, 24 h.

more, in the case of the ferrocenyl-derived cyclopalladated complexes (**4a**–**b**), the 1,2-disubstitution of the cyclopentadienyl ring results in the formation of planar chiral complexes. An AB spin system splitting pattern is observed for the PTA ligand.^{39–41} The NCH₂N protons resonate as two doublets corresponding to the different environments experienced by the axial and equatorial protons, while the PCH₂N protons resonate as a singlet (*ca.* 4.26 ppm), as expected for these types of cyclopalladated complexes.

Formation of the complexes is further confirmed by the ¹³C{¹H} NMR spectra. The imine carbon atom, which resonates at *ca.* 147 ppm for the free TSCs, shifts significantly downfield (*ca.* 162 ppm) for the complex. Furthermore, the imine carbon atom resonates as a doublet (*J* = 7.4 Hz), which is ascribed to coupling with the PTA phosphorus. A similar trend is observed for the carbon atom to which the palladium atom is bonded. The carbon atom resonates as a doublet (7.4–8.8 Hz) at 99.5 and *ca.* 136 ppm for the ferrocenyl- and aryl-derivatives, respectively. This further confirms C–H activation, and thus formation of the palladacycle.

³¹P{¹H} NMR spectroscopic analysis reveals one singlet for the phosphorus nuclei, resonating upfield at approximately –41.6 ppm for the ferrocenyl complexes (**4**) and approximately –49.7 ppm for complexes **5** and **6**. This confirms the presence of one phosphorus species. This is consistent with the

Fig. 1 ^1H NMR stability study of complex **5a** in $\text{DMSO-}d_6:\text{D}_2\text{O}$ (9:1, v/v) at 37 °C over 72 h.

literature values for analogous cyclopalladated compounds containing a PTA ligand.^{20,21} Infrared spectral analysis of the of the palladium-free compounds revealed an absorption band at *ca.* 1610 cm^{-1} which corresponds to the imine ($\text{C}=\text{N}$) stretching frequency.

Upon formation of the cyclopalladated complex, two absorption bands at around 1578 and 1553 cm^{-1} are observed which correspond to two $\text{C}=\text{N}$ stretching frequencies. The absorption band observed at the lower wavenumber is assigned to the palladium-coordinated imine, while the absorption band at the higher wavenumber corresponds to the newly formed $\text{C}=\text{N}$ bond in the cyclopalladated complexes. The formation of these complexes is further confirmed by mass spectrometry. The mass spectra for complexes **4–6** displayed peaks corresponding to either the molecular ion $[\text{M}]^+$ or the protonated form $[\text{M} + \text{H}]^+$.

Metal-based compounds which are stable in solution are important when ensuring that the tested compound is the

compound responsible for the observed biological activity. Therefore, as a model system, the stability of complex **5a** was investigated and monitored by ^1H NMR spectroscopy over a 72 h period at 37 °C. The ^1H NMR spectra (Fig. 1) of complex **5a** was recorded in $\text{DMSO-}d_6:\text{D}_2\text{O}$ (9:1, v/v). The spectra remain unchanged over the time period for the assay, suggesting that compound **5a** may be the compound responsible for any observed activity.

In vitro antiparasmodial and cytotoxicity evaluation

The dithiocarbamates, thiosemicarbazones (**1–3**) and the cyclopalladated complexes (**4–6**) were evaluated for their *in vitro* antiparasmodial activity against the CQ-sensitive (NF54) and CQ-resistant (Dd2) strains of *Plasmodium falciparum*. The cytotoxicity of selected compounds was evaluated against the Chinese Hamster Ovarian (CHO) cell-line. Chloroquine (CQDP) and artesunate were used as the control drugs for the parasite strains and emetine for the CHO cell-line. The IC_{50} values are listed in Table 1.

In general, introduction of the cyclopalladated entity resulted in an overall enhancement of activity (IC_{50} values below 2 μM) against the NF54 strain of *P. falciparum*, for the complexes (**4–6**) in comparison with the dithiocarbamates and TSCs. Comparing the three pairs of complexes (**4–6**), reveals that the Si-containing 3,4-dichloroacetophenoneTSC palladium complexes (**5**) were the most potent.

An IC_{50} value of below 5 μM was selected as the cut-off value for identifying potential lead compounds for further testing. Therefore, only those compounds displaying activity below 5 μM against the NF54 strain were further tested for their activity against the Dd2 strain. A decrease in activity was observed for the dithiocarbamates against the resistant strain, whereas the palladium-free TSCs were generally equipotent against the NF54 and Dd2 strains. However, incorporation of

^a $\text{RI} = \text{IC}_{50}(\text{Dd2})/\text{IC}_{50}(\text{NF54})$. ^b $\text{SI}_1 = \text{IC}_{50}(\text{CHO})/\text{IC}_{50}(\text{NF54})$. ^c $\text{SI}_2 = \text{IC}_{50}(\text{CHO})/\text{IC}_{50}(\text{Dd2})$; ND = not determined.

the palladium-PTA fragment, generally results in a slight increase in potency against the resistant Dd2 strain. These cyclopalladated complexes were not as active as ferroquine (Table 1).

The resistance indices [RI = IC₅₀ (Dd2)/IC₅₀ (NF54)] were calculated for compounds displaying activity against the Dd2 strain. A value below or close to 1 suggests that the compounds are more likely to be active against resistant strains. The RI values for the cyclopalladated complexes were generally below 1, indicating that incorporation of the palladium-PTA fragment, delivers complexes likely to be active against resistant strains relative to chloroquine (19.59) and artesunate (4.81). Overall, the thiosemicarbazone compounds displayed lower RI values than the controls.

The compounds containing a methylene spacer (**1a–6a**) were generally more potent, and thus only those compounds were further tested for their cytotoxicity against the CHO cell-line. Selectivity indices [SI = IC₅₀ (CHO)/IC₅₀ (NF54 or Dd2)] calculated for the dithiocarbamates revealed low SI values (<1) suggesting a lack of selectivity. As seen in Table 1, the thiosemicarbazone compounds (**2a**, **4a**, **5a**, **6a**) are more effective at killing parasitic cells as opposed to the mammalian CHO cells, with SI values higher than that observed for the dithiocarbamates. In terms of the cyclopalladated complexes, the Si-containing 3,4-dichloroacetophenoneTSC palladium complex (**5a**) displayed the best selectivity.

Conclusions

Two series of ferrocenyl- and aryl-derived organosilane TSCs were prepared, as well as their cyclopalladated complexes *via* C–H activation of the ring. The TSCs and cyclopalladated complexes were fully characterised using various spectroscopic and analytical techniques. Evaluation of the compounds against two strains of the malaria parasite *Plasmodium falciparum* revealed an enhancement of activity upon formation of the cyclopalladated complexes. The TSC compounds also displayed selective antiparasitic activity. A preliminary β -haematin (synthetic haemozoin) inhibition study of the cyclopalladated complex **5b** revealed that the formation of β -haematin, which is a target of antimalarial drugs, was not inhibited. Therefore, investigating other processes such as cysteine protease binding, or conducting ROS studies, could give insight into potential mechanistic routes by which these cyclopalladated complexes inhibit the parasite.

Materials and methods

Chemicals

All reagents and solvents were obtained from commercial sources (Sigma-Aldrich, Merck, Kimix, UkrOrgSyntez and FCH group) and, unless otherwise stated, were used as received. The Schiff-base dithiocarbamates,^{33,42} TSCs (**1a**, **2a**, **3a**)²⁶ and PdCl₂(PTA)₂⁴³ were prepared following literature methods.

Nuclear magnetic resonance (NMR) spectra were recorded using a Varian Mercury 300 spectrometer (¹H at 300.08 MHz), a Bruker 400 Biospin GmbH spectrometer (¹H at 400.200 MHz, ¹³C{¹H} at 100.600 MHz, ³¹P{¹H} at 161.80 MHz) or a Bruker 600 FT spectrometer (¹H at 600.100 MHz, ¹³C{¹H} at 150.60 MHz) at 30.0 °C. Coupling constants are reported in Hertz. Infrared (IR) spectra were determined using a Perkin Elmer Spectrum 100 FT-IR spectrometer and was carried out using an Attenuated Total Reflectance (ATR) unit. High resolution (HR) ESI-mass spectrometry was carried out using a Waters API Quattro instrument in the positive mode. EI-mass spectrometry was carried out in the positive mode using a JEOL GCmateII apparatus. Elemental analyses (C, H and N) were recorded on a Thermo Flash 1112 Series CHNS-O Analyser. Melting points were recorded using a Buchi B-540 melting point apparatus and are uncorrected.

Synthesis of thiosemicarbazones

Thiosemicarbazone 1b. Anhydrous ethanol (10.0 mL) was added to 3-aminopropyl-(trimethyl)silane (0.560 mL, 3.34 mmol) under N₂. The addition of ferrocenyl dithiocarbamate (0.457 g, 1.37 mmol) resulted in a red solution which was refluxed in the dark for 7 h. The solvent was removed *in vacuo* to yield a brown oil which was extracted using DCM (10.0 mL) and washed with water (3 × 20.0 mL). The crude product was further purified by column chromatography on deactivated alumina with hexane–ethyl acetate (30 : 70, v/v) as eluent. Compound **1b** was isolated as an oily-brown solid (0.352 g, 62%). Anal. Calcd (%) for C₁₉H₂₉FeN₃SiS₂O: C 54.34; H 7.08; N 10.01; Found C 54.66; H 7.27; N 9.90. IR (ATR) ν_{max} /cm⁻¹: 1599w (C=N). ¹H NMR (400.22 MHz, DMSO-*d*₆): δ (ppm) = 9.84 (1H, s, NNH); 8.22 (1H, t, ³J_{HH} = 6.0 Hz, NH); 4.79 (2H, t, ³J_{HH} = 3.6 Hz, C₅H₄); 4.37 (2H, t, ³J_{HH} = 3.6 Hz, C₅H₄); 4.18 (5H, s, C₅H₅); 3.52 (2H, m, CH₂); 2.19 (3H, s, CH₃); 1.58 (2H, m, CH₂); 0.48 (2H, m, CH₂); 0.01 (9H, s, Si(CH₃)₃). ¹³C{¹H} NMR (150.60 MHz, DMSO-*d*₆): δ (ppm) = 177.6 (C=S); 150.7 (C=N); 83.7, 70.2, 69.5, 67.7 (Fc); 47.0, 23.9, 15.5 (CH₂); 13.7 (CH₃); -1.09 (Si(CH₃)₃). EI⁺-MS (*m/z*) 415.03 ([M]⁺, 100%).

General method for the synthesis of **2b** and **3b**

Anhydrous ethanol (10.0 mL) was added to the amine under N₂, followed by the addition of 3,4-dichloroacetophenone dithiocarbamate. The solution was refluxed for 24 h. The addition of water (10.0 mL) resulted in the precipitation of a white solid which was collected by suction filtration.

Thiosemicarbazone 2b. 3-Aminopropyl(trimethyl)silane (0.320 mL, 1.91 mmol); 3,4-dichloroacetophenone dithiocarbamate (0.500 g, 1.71 mmol). Compound **2b** was isolated as a white solid (0.594 g, 92%). M.p.: 110.7–111.3 °C. Anal. calcd (%) for C₁₅H₂₃Cl₂N₃SiS: C 47.99; H 6.18; N 11.20; Found C 47.65; H 6.38; N 11.06. Synthesis of cyclopalladated complexes

General method. Excess triethylamine (0.200 mL) was added to a solution of the thiosemicarbazone dissolved in anhydrous ethanol, allowed to stir for 10 min, followed by the addition of one equivalent of the palladium precursor $\text{cis}[\text{PdCl}_2(\text{PTA})_2]$. The reaction mixture was refluxed for 24 h, and the resulting solid was collected by suction filtration. Compound **4b** was synthesised in the dark under N_2 . The solid was purified by washing with a minimum volume of hot methanol to remove phosphorus impurity.

Cyclopalladated complex 4a. Compound **1a** (0.0738 g, 0.106 mmol); $\text{cis}[\text{PdCl}_2(\text{PTA})_2]$ (0.0525 g, 0.107 mmol). Compound **4a** was isolated as a red powder (0.0434 g, 63%). M.p.: 266.8 °C (decomposition w/o melting). Anal. Calcd (%) for $\text{C}_{23}\text{H}_{35}\text{FeN}_6\text{PdPSiS}$: C 42.57, H 5.44, N 12.95; Found C 42.13, H 5.53, N 13.03. DMSO : D₂O stability study

Cyclopalladated complexes **5a** was dissolved in $\text{DMSO}-d_6$: D_2O (9 : 1, v/v) and the ^1H NMR spectrum recorded at 0 h. The solution was warmed at 37 °C, and the stability monitored by ^1H NMR spectroscopy at 24, 48 and 72 h time intervals to confirm stability of compound during the *in vitro* assay time period.

Plasmodium falciparum assay. Continuous *in vitro* cultures of asexual erythrocyte stages of *P. falciparum* were maintained using a modified method of Trager and Jensen.⁴⁴ Quantitative assessment of antiparasmodial activity *in vitro* was determined via the parasite lactate dehydrogenase assay using a modified method described by Makler.⁴⁵ Antiparasmodial assay was conducted according to previously published methods.⁴⁵ A full dose-response was performed for all compounds to determine the concentration inhibiting 50% of parasite growth (IC_{50} value). Test samples were tested at a starting concentration of $100 \mu\text{g ml}^{-1}$, which was then serially diluted 2-fold in complete medium to give 10 concentrations; with the lowest concentration being $0.2 \mu\text{g ml}^{-1}$. Reference drugs were tested at a starting concentration of 1000 ng ml^{-1} . Active compounds were retested at starting concentrations of $10 \mu\text{g ml}^{-1}$ or 1000 ng ml^{-1} . The highest concentration of solvent to which the parasites were exposed had no measurable effect on the parasite viability (data not shown). The IC_{50} values were obtained using a non-linear dose-response curve fitting analysis via Graph Pad Prism v.4.0 software.

Cytotoxicity assay

The MTT-assay is used as a colorimetric assay for cellular growth and survival, and compares well with other available assays.^{46,47} The test samples were tested in triplicate on one occasion. The same stock solutions prepared for the antiparasmodial activity testing were used for the cytotoxicity tests.

Dilutions were prepared on the day of the experiment in complete medium. Emetine was used as the reference drug. The initial concentration of emetine was $100 \mu\text{g ml}^{-1}$, which was serially diluted in complete medium with 10-fold dilutions to give 6 concentrations, the lowest being $0.001 \mu\text{g ml}^{-1}$. The same dilution technique was applied to the all test samples. The highest concentration of solvent to which the cells were exposed to had no measurable effect on the cell viability (data not shown). The IC_{50} values were obtained from full dose response curves, using a non-linear dose-response curve fitting analysis via GraphPad Prism v.4 software.

Conflict of interest

The authors declare no competing financial interest.

Acknowledgements

Financial support from the University of Cape Town, the National Research Foundation (NRF) of South Africa and the Medical Research Council (MRC) of South Africa is gratefully acknowledged. Even though the work is supported by the MRC, the views and opinions expressed are not those of the MRC but of the authors of the material produced or published. The South African Research Chairs initiative of the Department of Science and Technology administered through the South African National Research Foundation is gratefully acknowledged for support (KC).
