# Bimetallic rare-earth/platinum complexes ligated by phosphinoamides†

Franziska Völcker and Peter W. Roesky\*

The heterometallic early-late 5d/4f binuclear phosphinoamido Ln/Pt(0) complexes [(Ph<sub>2</sub>PNHPh) Pt{ $\mu$ -(Ph<sub>2</sub>PNPh)} $_3Ln(\mu$ -Cl)Li(THF) $_3$ ] (Ln = Y (**1a**), Lu (**1b**)) were obtained by reaction of [Li(THF) $_4$ ] [(Ph<sub>2</sub>PNPh) $_4Ln$ ] (Ln = Y, Lu) with the Pt(0) complex [Pt(tBu $_3$ P) $_2$ ] in the presence of LiCl. In the absence of LiCl the corresponding Ln/Pt(0) complexes [(Ph $_2$ PNHPh)Pt{ $\mu$ -(Ph $_2$ PNPh)} $_3Ln\{\eta^2$ -(Ph $_2$ PNPh)}][Li(THF) $_4$ ] (Ln = Y (**2a**), Lu (**2b**)) were isolated. Both kind of complexes decompose in solution. The Pt(0) complex [Pt(Ph $_2$ PNHPh) $_4$ ] (**3**) was identified as one of these decomposition products.

### Introduction

Homo- and heterobimetallic complexes have been studied for catalytic application and small molecule activation over recent years.<sup>1,2</sup> Some of these compounds show cooperative and synergistic effects that can arise from the simultaneous or consecutive action of different metal centers in different media.<sup>2</sup> Inspired by nature, the concept of cooperative bimetallic catalysis has been employed for the synthesis of numerous artificial catalysts. The emerging field of homo- and heterobimetallic and polymetallic catalyst systems has been summarized in several review articles recently.2-6 Within this area heterobimetallic early/late complexes<sup>7,8</sup> having interactions between a hard Lewis acidic early metal atom and a soft Lewis basic late metal atom are of interest because they feature significantly different reaction sites. This makes them interesting for potential applications in catalysis.9 For the synthesis of heterobimetallic early/late complexes carbonyl-, hydride-, halide-, selenide-, and thiolate ligands were used as bridging ligands.1 Recently, Thomas et al. reported heterobimetallic transition metal complexes with metal-to-metal bonds bridged by phosphinoamido ligands.9 The known combinations of metals realized by this concept are bimetallic complexes, e.g. Co/Ti, <sup>10,11</sup> Co/Zr, <sup>9,12-16</sup> Co/Hf, <sup>17</sup> Pt/Zr, <sup>18</sup> V/Fe, <sup>19</sup> Nb/Co, <sup>20</sup> Ta/Co,<sup>20</sup> and Co/U.<sup>21</sup>

In contrast to transition metal complexes, heterobimetallic early/late complexes<sup>7,8</sup> containing rare-earth metals are far less common. Thus, only few complexes of the rare-earth elements with non-supported metal-to-metal bonds to a transition metal

Institut für Anorganische Chemie, Karlsruher Institut für Technologie (KIT), Engesserstr. 15, Geb. 30.45, 76131 Karlsruhe, Germany. were reported.<sup>17</sup> Examples include complexes with Lu–Ru,<sup>22</sup> Ln–Re (Ln = La, Sm, Yb, Lu),<sup>20,23–25</sup> Nd–Fe,<sup>26</sup> and Yb–Fe bonds.<sup>27</sup>

Heterobimetallic compounds, which have a rare-earth metal atom and a rhodium, palladium, or platinum atom in close proximity (distance of less than 3.5 Å) are also not very common. Kempe *et al.* reported some Nd/Rh and Nd/Pd complexes, <sup>28,29</sup> in which the metals are brought closely together by bis(aminopyridinato) ligands. Hou *et al.* recently reported heterobimetallic rare-earth metal/platinum complexes. In these half-sandwich rare-earth metal alkyl complexes Cp ligands with a phosphine side arm were used. <sup>30</sup>

As seen by these few examples one of the big challenges that still remain is the synthesis of heterobimetallic early/late complexes containing rare-earth metals. Lately, we reported the synthesis of the heterometallic early-late 4d/4f bi- and trinuclear phosphinoamido Ln/Pd(0) complexes  $[(Ph_2PNHPh)]Pd\{\mu-(Ph_2PNPh)\}_3Ln(\mu-Cl)Li(THF)_3]$  (Ln = Y (Ia), Lu (Ib)) and  $[Li(THF)_4][\{(Ph_2PNHPh)Pd\}_2\{\mu-(Ph_2PNPh)\}_4Ln]$  (Ln = Y (IIa), Lu (IIb)) (Scheme 1).  $^{31,32}$  The latter compounds are the first early/late trimetallic phosphinoamido complexes. Compounds Ia,b and IIa,b were obtained by reaction of  $[Li(THF)_4]$ 

Ln = Y (la), Lu (lb)

Scheme 1 Bi- and trinuclear phosphinoamido Ln/Pd(0) complexes.31

Paper Dalton Transactions

[(Ph<sub>2</sub>PNPh)<sub>4</sub>Ln] (Ln = Y, Lu)<sup>33–36</sup> with the palladium allyl complex [Pd<sub>2</sub>(C<sub>3</sub>H<sub>5</sub>)<sub>2</sub>Cl<sub>2</sub>]. A reduction of the palladium atoms was observed upon the formation of the bi- and trimetallic compounds **Ia,b** and **IIa,b**. Although the metal atoms are forced into close proximity by the phosphinoamido ligands, quantum chemical calculations of [(Ph<sub>2</sub>PNHPh)Pd{ $\mu$ -(Ph<sub>2</sub>-PNPh)}<sub>3</sub>Lu( $\mu$ -Cl)Li(THF)<sub>3</sub>] showed only weak metal-to-metal interactions. <sup>31,32</sup>

Motivated by these initial results, we were interested in extending our studies on heterobimetallic early/late complexes containing rare-earth metals. Herein, we now report heterobimetallic rare-earth metal/platinum complexes bridged by phosphinoamido ligands.

### Results and discussion

The palladium complexes Ia,b were obtained most efficiently by the addition of LiCl to the reaction mixture giving the desired complexes. In a similar protocol, the reaction of  $[Li(THF)_4][(Ph_2PNPh)_4Ln]$  (Ln = Y, Lu) with the Pt(0) precursor  $[Pt(P(tBu)_3)_2]$  in the presence of LiCl resulted after crystallizain the Ln/Pt(0)complexes [(Ph2PNHPh)Pt{µ- $(Ph_2PNPh)_3Ln(\mu-Cl)Li(THF)_3$  (Ln = Y (1a), Lu (1b)) in moderate yields (Scheme 2). Formally, the Pt atom inserts into the weak Ln-P bonds forming the desired heterobimetallic complexes. We presume that some decomposition occurs and Ph<sub>2</sub>PN(H)Ph, which is coordinated to the Pt atom, is formed as a side-product. In contrast to the formation of the Pd(0) complexes Ia,b, which were obtained only in a reductive approach from a Pd(II) source, compounds 1a,b are directly accessible from a Pt(0) precursor. By using Pt(II) salts as starting material no traceable products were obtained.

Although the reactions leading to **1a** and **1b** seem, at first glance, quiet similar, their accessibility is significantly different. Whereas **1a** was obtained straight forward in a reproducible way, the preparation of **1b** is more difficult.

Single crystals of 1a,b suitable for X-ray diffraction were obtained by crystallization from THF/toluene/pentane (Fig. 1 and S1†). Compounds 1a,b crystallize in the triclinic space group  $P\bar{1}$  with one molecule of the complexes in the asymmetric unit. Furthermore, one molecule of THF and toluene were localized each in the asymmetric unit. The toluene molecule in 1a showed a strong disorder and was thus suppressed by using Olex solvent mask. The both compounds, the Ln and the Pt atoms are forced in close proximity by three bridging  $\mu$ -(Ph<sub>2</sub>PNPh) ligands. As expected the soft P atom binds to the Pt atom, whereas the hard nitrogen atoms coordinate to the rare-earth metal atom. In both compounds, the Li atom is

Scheme 2 Synthesis of 1a,b.

coordinated to the Ln atom via a μ-Cl bridge. The rare-earth atoms are thus five-fold coordinated by three Ph2PNPh ligands, one molecule of THF and the chlorine atom. A distorted trigonal bipyramidal coordination polyhedron with the THF oxygen atom and N3 in the axis is formed. The Ln-N bond distances (1a: 2.291(3) Å-2.347(3); 1b: 2.242(6)-2.297(6) Å) are in the range of **Ia,b** (av. 2.317 Å (**Ia**), 2.262 Å (**Ib**)). <sup>31</sup> The Ln-Cl bond lengths are 2.6525(14) Å (1a), 2.601(2) Å (1b)). The Pt atom is four-fold coordinated by the phosphorous atoms of three µ-(Ph2PNPh) ligands and one Ph2PNHPh ligand. A distorted tetrahedral coordination polyhedron is formed by the four P atoms around the Pt atom. The Pt-P bond distances are av. 2.3354 Å (1a), 2.328 Å (1b). Although the Pt atom has a slightly larger van-der-Waals radius in comparison to Pd, the Ln-Pt distances in **1a,b** (3.0063(8) Å (**1a**), 2.9523(9) Å (**1b**)) are in the range of those in the Ln-Pd complexes Ia,b (2.9898(6) Å (Ia), 2.9031(11) Å (Ib)). This is clearly showing that the three μ-(Ph<sub>2</sub>PNPh) ligands are forcing the metal atoms into close

Since traces of LiCl within the starting material [Li(THF)<sub>4</sub>] [(Ph<sub>2</sub>PNPh)<sub>4</sub>Y] (Ln = Y, Lu) resulted in the reaction with [Pt( $P(tBu)_3$ )<sub>2</sub>] in **1a**, we improved our synthesis of [Li(THF)<sub>4</sub>]

Scheme 3 Synthesis of 2a,b.

[(Ph<sub>2</sub>PNPh)<sub>4</sub>Ln]. [Li(THF)<sub>4</sub>]](Ph<sub>2</sub>PNPh)<sub>4</sub>Ln]<sup>33-36</sup> is obtained by the reaction of LnCl<sub>3</sub> with LiPPh<sub>2</sub>NPh in a 1:4 molar ratio. Usually, the product can be directly obtained by crystallization from THF/n-pentane. But obviously the bulk material is sometimes contaminated with traces of LiCl. By extraction of the crude product with toluene before crystallization, the contamination of the product with LiCl is avoided. The desired product is thus obtained in higher purity.

Reaction of very pure  $[Li(THF)_4][(Ph_2PNPh)_4Ln](Ln = Y, Lu)$ with  $[Pt(P(tBu)_3)_2]$  gave the bimetallic compounds  $[(Ph_2PNHPh)]$  $Pt{\mu-(Ph_2PNPh)}_3Ln{\eta^2-(Ph_2PNPh)}][Li(THF)_4] (Ln = Y (2a), Lu$ (2b)) as yellow crystals (Scheme 3). The formation of 2a,b is similar to 1a,b. Again, the Pt(0) atom formally inserts into three of the Ln-P bonds. The fourth PPh2NPh ligand remains in a  $\eta^2$ -coordination mode on the Ln atom. The Pt atom forms a similar coordination polyhedron as observed in 1a,b.

As seen for the formation of compounds 1a,b, there is a difference in reactivity. Upon workup, 2a was obtained as pure material in single crystalline form and complete characterization was possible. In contrast, the reaction leading to 2b is not quantitative. Even after prolonged reaction times the workup of 2b resulted in a mixture of the desired product and [Li(THF)<sub>4</sub>][(Ph<sub>2</sub>PNPh)<sub>4</sub>Lu]. The solid-state structures of both 2a and 2b were established by single crystal X-ray diffraction but for 2b no further analytical data could be collected.

Compound 2a crystallizes in the monoclinic space group Cc with one molecule of the complexes in the asymmetric unit. Although the X-ray data collected from 2b was very poor, its composition was deduced from the difference Fourier map (Fig. S2†). Bond angles and distances of 2b thus are not discussed. Compounds 2a,b consist of a [(Ph<sub>2</sub>PNHPh)Pt{μ- $(Ph_2PNPh)\}_3Ln\{\eta^2\text{-}(Ph_2PNPh)\}]^- \ anion \ and \ a \ \lceil Li(THF)_4\rceil^+ \ cation$ (Fig. 2). As seen in 1a,b the Pt atom in 2a,b is four foldcoordinated by three µ-(Ph2PNPh) and one Ph2PNHPh ligand resulting in a distorted tetrahedral coordination polyhedron, which is formed by the four P atoms around the Pt atom. Since the central part of the [(Ph<sub>2</sub>PNHPh)Pt{μ-(Ph<sub>2</sub>PNPh)}<sub>3</sub>- $Ln\{\eta^2-(Ph_2PNPh)\}$  anion is similar to **1a,b** the Y-Pt distance in 2a (3.032(2) Å) is as expected. The main difference between 2a,b and 1a,b is the coordination sphere of the Ln atom. Instead of a molecule of THF and a chlorine atom, which are bound to the Ln atom in 1a,b, a η<sup>2</sup>-coordinated PPh<sub>2</sub>NPh ligand is bound to the lanthanide atom in 2a,b. Additionally, the N atoms of three bridging μ-(Ph<sub>2</sub>PNPh) ligands coordinate to the Ln atom resulting in a five-fold coordinated metal atom. The Ln-N bonds in **2a** range from 2.285(12) Å to 2.301(2) Å.

As observed for Ia,b, also the Pt complexes 1a,b and 2a,b decompose in solution. This is one explanation for the low yields and the formation of the protonated ligand PPh<sub>2</sub>NHPh.

Fig. 2 Solid-state structure of the anion of 2a. Carbon bound hydrogen atoms are omitted for clarity. Compound 2b is similar. Selected bond lengths [A], angles [°]: 2a: Pt-Y 3.032(2), Pt-P1 2.367(4), Pt-P2 2.301(4), Pt-P3 2.330(4), Pt-P5 2.371(4), Y-P4 2.931(4), Y-N1 2.285(12), Y-N2 2.309(13), Y-N3 2.300(15), Y-N4 2.315(15), P1-N1 1.659(13), P2-N2 1.649(13), P3-N3 1.663(14), P4-N4 1.643(12); P1-Pt-P5 114.73(2), P2-Pt-P1 107.47(14), P2-Pt-P3 111.18(15), P2-Pt-P5 105.54(15), P3-Pt-P1 109.77(14), P3-Pt-P5 108.12(15), N4-Y-P4 34.0(3), N1-Y-N2 114.9(5), N1-Y-N3 103.0(5), N1-Y-N4 126.2(4), N3-Y-N2 120.0(5), N3-Y-N4 99.1(5).

The <sup>31</sup>P{<sup>1</sup>H} NMR spectra show fast decomposition of all compounds in various solvents. In  $d_8$ -THF a large number of signals were observed. In C<sub>6</sub>D<sub>6</sub> major signals with the corresponding <sup>195</sup>Pt satellites were observed in the <sup>31</sup>P{<sup>1</sup>H} NMR spectra of 1a,b and 2a (Fig. S3-S5†). However, the ratio varies from sample to sample and further decomposition signals were sometimes also observed as well. As a result of the fast decomposition, there remain significant uncertainties of the correct assignment of the signals. A 1H, 195Pt HMBC NMR spectrum was also not conclusive.

One of the decomposition products could be identified. From a saturated solution of 1a in  $d_8$ -THF the Pt(0) complex [Pt(PPh<sub>2</sub>NHPh)<sub>4</sub>] (3) crystallized once in a NMR tube. Although 3 was not fully characterized and the X-ray data collected was poor, its composition was deduced from the difference Fourier map (Fig. 3) giving thus some insight into the decomposition pathway. Moreover, 3 was also identified by ESI-MS

Fig. 3 Solid-state structure of the anion of 3. Carbon bound hydrogen atoms are omitted for clarity.

spectroscopy of a solution of **1a**. In **3**, the Pt(0) atom is four-fold coordinated by the phosphorous atoms of four PPh<sub>2</sub>NHPh ligands in a tetrahedral fashion. The only slightly related phosphinoamido structure of platinum reported in the literature is found in the Pt(1) species [Pt(NPhPPh<sub>2</sub>)(HNPhPPh<sub>2</sub>)]<sub>2</sub>, having a Pt-Pt bond.<sup>38</sup>

### Experimental<sup>32</sup>

**Paper** 

All manipulations of air-sensitive materials were performed with the rigorous exclusion of oxygen and moisture in Schlenk-type glassware either on a dual manifold Schlenk line, interfaced to a high vacuum (10<sup>-3</sup> torr) line, or in an argonfilled MBraun glove box. Elemental analyses were carried out with an Elementar vario Micro Cube. Hydrocarbon solvents were predried using an MBraun solvent purification system (SPS-800) and then they were degassed, dried and stored in vacuo over LiAlH<sub>4</sub>. Tetrahydrofuran was distilled under nitrogen from potassium before storage over LiAlH<sub>4</sub>. Deuterated solvents were obtained from Euro-Isotop (99.5 atom% D) and were degassed, dried and stored in vacuo over Na/K alloy in resealable flasks. <sup>1</sup>H and <sup>31</sup>P{<sup>1</sup>H} NMR spectra were recorded on a Bruker Avance II 300 MHz or Avance 400 MHz. <sup>1</sup>H chemical shifts were referenced to the residual deuterated solvents and are reported relative to tetramethylsilane, <sup>31</sup>P{<sup>1</sup>H} was referenced to external 85% phosphoric acid. IR spectra were obtained on a Bruker Tensor 37 FTIR spectrometer equipped with a room temperature DLaTGS detector and a diamond ATR (attenuated total reflection) unit. Raman spectra were recorded on a Bruker MultiRAM spectrometer.

<sup>195</sup>Pt-NMR spectra were recorded at 300 K on a Bruker Avance II 600 spectrometer using a double-resonance <sup>1</sup>H-BBI probe head. Platinum frequencies were determined by an ultrabroadband version of a gradient selected <sup>1</sup>H,<sup>195</sup>Pt-HMBC.<sup>39</sup> Due to the very large chemical shift range of platinum complexes (15 000 ppm, 1.94 MHz @ 14.1 T), it is not possible to cover this range in one conventional experiment. Conventional experiments are acquired with hard pulses that can excite bandwidth of about 50 kHz. Broadband spectra are achieved *via* application of broadband saturation pulses on platinum, which have been designed by optimal control derived optimizations.<sup>40–45</sup>

[Pt( $P(tBu)_3$ )<sub>2</sub>] (ABCR) was used as purchased from commercial sources without further purification. [Li(THF)<sub>4</sub>] [(Ph<sub>2</sub>PNPh)<sub>4</sub>Ln] (Ln = Y, Lu), <sup>31,34</sup> LnCl<sub>3</sub> (Ln = Y, Lu), <sup>46</sup> and LiPh<sub>2</sub>PNPh <sup>38,47</sup> were prepared according to literature procedure.

### $[(Ph_2PNHPh)Pt{\mu-(Ph_2PNPh)}_3Y(\mu-Cl)Li(thf)_3](1a)$

15 ml THF was condensed at -78 °C onto a mixture of 186 mg (0.125 mmol) [Li(THF)<sub>4</sub>][(Ph<sub>2</sub>PNPh)<sub>4</sub>Y], 75 mg (0.125 mmol) bis(tri-tert-butylphosphine)platinum(0) and 5.3 mg (0.125 mmol) anhydrous lithium chloride. The orange solution was stirred for 3 h at ambient temperature. After the reaction period the solution was concentrated and 10 ml toluene was

condensed onto the mixture. After filtration, the THF/toluene mixture was layered with toluene and with n-pentane. After one day 50 mg (0.035 mmol, 28%) of yellow crystals were formed. In a few cases the formation of colorless crystals of  $[\text{Li}(\text{THF})_4][(\text{Ph}_2\text{PNPh})_4Y]$  was observed, which could be separated from the yellow crystals in the glove box.

### $[(Ph_2PNHPh)Pt\{\mu-(Ph_2PNPh)\}_3Lu(\mu-Cl)Li(thf)_3] (1b)$

15 ml THF was condensed at -78 °C onto a mixture of 200 mg (0.127 mmol) [Li(THF)<sub>4</sub>][(Ph<sub>2</sub>PNPh)<sub>4</sub>Lu], 76 mg (0.127 mmol) bis(tri-tert-butylphosphine)platinum(0) and 2.7 mg (0.063 mmol) anhydrous lithium chloride. The orange solution was stirred over night at ambient temperature. After the reaction period the solution was concentrated and 10 ml toluene was condensed onto the mixture. After filtration, the THF/toluene mixture was layered with toluene and with n-pentane. After one day 36 mg (0.020 mmol, 16%) of yellow crystals were formed. Additionally the formation of colorless crystals of [Li(THF)<sub>4</sub>][(PPh<sub>2</sub>NPh)<sub>4</sub>Lu] was observed, which could be separated from the yellow crystals in the glove box. When the product was recrystallized several times, crystals of 2b were also formed.

# Improved synthesis of [Li(thf)<sub>4</sub>][Ln(Ph<sub>2</sub>PNPh)<sub>4</sub>] (Ln = Y, Lu) to avoid traces of LiCl<sup>34</sup>

Ln = Y. 15 ml THF was condensed at -78 °C onto a mixture of 120 mg (0.615 mmol) YCl<sub>3</sub> and 696 mg (2.46 mmol) LiPh<sub>2</sub>PNPh. The solution was stirred over night at ambient temperature. After removing the solvent the residue was dissolved in 20 ml toluene and the solution was filtered. The solvent was removed and the oily residue was washed with n-pentane. The obtained solid was dissolved in THF and n-pentane was layered on top of the solution. After one day

200 mg (0.134 mmol, 22%) colorless crystals could be obtained.

**Ln** = **Lu**. 200 mg (0.711 mmol) LuCl<sub>3</sub> and 805 mg (2.84 mmol) LiPh<sub>2</sub>PNPh. Yield: 297 mg (0.212 mmol, 30%).

### $[(Ph_2PNHPh)Pt{\mu-(Ph_2PNPh)}_3Y{\eta^2-(Ph_2PNPh)}][Li(thf)_4] (2a)$

15 ml of THF was condensed at -78 °C onto a mixture of 186 mg (0.125 mmol) [Li(thf)<sub>4</sub>][(Ph<sub>2</sub>PNPh)<sub>4</sub>Y] and 75 mg (0.125 mmol) bis(tri-*tert*-butylphosphine)-platinum(0). The mixture was stirred for 4 h at ambient temperature. After the reaction period the solution was concentrated and 10 ml of toluene was condensed onto the mixture. After filtration, the THF/toluene mixture was layered with toluene and with n-pentane. After one day 23 mg (0.012 mmol, 9%) yellow crystals were formed.

IR (ATR):  $\tilde{\nu}$  (cm<sup>-1</sup>) = 3381 (w), 3045 (w), 2924 (w), 2854 (w), 1598 (m), 1494 (m), 1472 (m), 1432 (m), 1389 (m), 1280 (m), 1226 (m), 1180 (w), 1155 (w), 1092 (m), 1066 (m), 1027 (m), 996 (m), 894 (m), 822 (w), 740 (s), 691 (s) 617 (m), 593 (s), 507 (s), 464 (s), 429 (s). – Raman:  $\tilde{\nu}$  (cm<sup>-1</sup>) = 3056 (s), 1585 (vs), 1476 (w), 1433 (w), 1396 (w), 1284 (w), 1234 (w), 1186 (w), 1158 (w), 1093 (m), 1031 (m), 1000 (vs), 898 (w), 800 (w), 769 (w), 698 (w), 619 (w), 525 (w), 487 (w), 412 (w), 255 (w), 225 (w), 194 (w), 173 (w). – EA:  $C_{106}H_{109}LiN_5O_4P_5PtY$  (1962.83): calc: C 64.86, H 5.60, N 3.57; exp: C 64.11, H 5.77, N 3.21.

### $[(Ph_2PNHPh)Pt{\mu-(Ph_2PNPh)}_3Lu{\eta^2-(Ph_2PNPh)}][Li(thf)_4](2b)$

15 ml of THF was condensed at -78 °C onto a mixture of 140 mg (0.089 mmol) [Li(thf)<sub>4</sub>][(Ph<sub>2</sub>PNPh)<sub>4</sub>Lu] and 53 mg (0.089 mmol) bis(tri-tert-butylphosphine)platinum(0). The mixture was stirred for 2 days at ambient temperature. After the reaction period the solution was concentrated and 10 ml of toluene was condensed onto the mixture. After filtration the THF/toluene mixture was layered with toluene and with n-pentane. After two times of recrystallization yellow (2b) and colourless crystals of [Li(THF)<sub>4</sub>][(PPh<sub>2</sub>NPh)<sub>4</sub>Lu] could be obtained, which could not be separated from each other.

#### X-Ray-crystallographic studies of 1a, 1b, 2a, 2b and 3

A suitable crystal was covered in mineral oil (Aldrich) and mounted on a glass fiber. The crystal was transferred directly to the cold stream of a STOE IPDS 2 or STOE StadiVari diffractometer.

All structures were solved using SHELXS-2013.<sup>48</sup> The remaining non-hydrogen atoms were located from difference Fourier map calculations. The refinements were carried out by using full-matrix least-squares techniques on F, minimizing the function  $(F_{\rm o}-F_{\rm c})^2$ , where the weight is defined as  $4F_{\rm o}^{\ 2}/2(F_{\rm o}^{\ 2})$  and  $F_{\rm o}$  and  $F_{\rm c}$  are the observed and calculated structure factor amplitudes using the program SHELXL-2013.<sup>48</sup> Carbon-bound hydrogen atom positions were calculated. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities in each case were of no chemical significance. Positional

parameters, hydrogen atom parameters, thermal parameters, bond lengths and angles have been deposited as ESI.†

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as a supplementary-publication no. CCDC 1450174–1450176.

Crystal data for **1a**:  $C_{88}H_{93}ClLiN_4O_4P_4PtY\cdot C_4H_8O$ , M=1793.03, a=13.302(3) Å, b=15.181(3) Å, c=22.663(5) Å,  $\alpha=99.59(3)^\circ$ ,  $\beta=98.88(3)^\circ$ ,  $\gamma=99.85(3)^\circ$ , V=4366.3(16) Å<sup>3</sup>, T=150(2) K, space group  $P\bar{1}$ , Z=2,  $\mu(Mo~K\alpha)=2.418~mm^{-1}$ , 31~469 reflections measured, 15~963 independent reflections  $(R_{int}=0.0478)$ . The final  $R_1$  values were  $0.0368~(I>2\sigma(I))$ . The final  $wR(F^2)$  values were  $0.0918~(I>2\sigma(I))$ . The final  $R_1$  values were 0.0451~(all~data). The final  $wR(F^2)$  values were 0.0947~(all~data). The goodness of fit on  $F^2$  was 0.988.

Crystal data for **1b**:  $C_{88}H_{93}ClLiLuN_4O_4P_4Pt\cdot C_4H_8O\cdot C_7H_8$ , M=1971.23, a=13.388(3) Å, b=15.201(3) Å, c=22.573(5) Å,  $\alpha=99.85(3)^\circ$ ,  $\beta=98.77(3)^\circ$ ,  $\gamma=97.53(3)^\circ$ , V=4414.6(16) Å<sup>3</sup>, T=210(2) K, space group  $P\bar{1}$ , Z=2,  $\mu(Mo~K\alpha)=2.853~mm^{-1}$ , 34~017 reflections measured, 17 155 independent reflections  $(R_{int}=0.0947)$ . The final  $R_1$  values were 0.0469  $(I>2\sigma(I))$ . The final  $wR(F^2)$  values were 0.0629  $(I>2\sigma(I))$ . The final  $R_1$  values were 0.1300 (all data). The final  $wR(F^2)$  values were 0.0763 (all data). The goodness of fit on  $F^2$  was 0.649.

Crystal data for **2a**:  $C_{90}H_{76}N_5P_5PtY\cdot C_{16}H_{32}LiO_4$ , M=1961.76, a=23.628(5) Å, b=14.886(3) Å, c=28.196(6) Å,  $\beta=107.47(3)^\circ$ , V=9459(4) Å<sup>3</sup>, T=209 K, space group Cc, Z=4,  $\mu(Mo\ K\alpha)=2.22\ mm^{-1}$ , 36 018 reflections measured, 18 329 independent reflections ( $R_{\rm int}=0.1126$ ). The final  $R_1$  values were 0.0639 ( $I>2\sigma(I)$ ). The final  $wR(F^2)$  values were 0.1085 ( $I>2\sigma(I)$ ). The final  $R_1$  values were 0.1064 (all data). The final  $wR(F^2)$  values were 0.1212 (all data). The goodness of fit on  $F^2$  was 0.864.

Crystal data for 3:  $C_{72}H_{64}N_4P_4Pt\cdot 6(C_4H_8O)$ , M=1736.86, a=18.281(2) Å, b=18.250(2) Å, c=18.261(2) Å,  $\alpha=104.797(7)^\circ$ ,  $\beta=104.736(9)^\circ$ ,  $\gamma=119.060(9)^\circ$ , V=4603.9(9) Å<sup>3</sup>, T=100 K, space group  $P\bar{1}$ , Z=2. Due to the fast decomposition no full data set could be acquired.

### Conclusions

As already noted in our communication on Ln/Pd complexes<sup>31</sup> the chemistry of heterobimetallic Ln/Pt complexes supported by phosphinoamido ligands is significantly different from the well-established family of heterobimetallic transition metal complexes with phosphinoamido ligands. The most obvious differences are:

- 1. The Ln/Pd and Ln/Pt phosphinoamido complexes, which were synthesized so far, are significantly less stable than phosphinoamido transition metal complexes, *e.g.* Co/Zr. This hampers an investigation of their reactivity.
- 2. As shown by our recently reported quantum chemical calculations for **Ib**, <sup>31</sup> the short metal-to-metal distances are a result of ligand effects, rather than of metal-metal bonds.

The lack of significant metal-to-metal interaction is a result of the strong ionic bonding contribution generally observed in rare-earth chemistry. The lack of stability of the heterobimetal-lic rare-earth/platinum metal complexes supported by phosphinoamido compounds may also be a result of the difference in bonding compared to pure heterobimetallic transition metals.
