Ruth Patchett and Adrian B. Chaplin*

The preparation and coordination chemistry of 5,17-bis(3-methyl-1-imidazol-2-ylidene)-25,26,27,28-tetrapropoxycalix[4]arene (**1**) is described. Starting from the bis(imidazolium) pro-ligand **1.2HI**, the free carbene **1** was readily generated in solution through deprotonation using $\text{K}[\text{O}^t\text{Bu}]$ and its reactivity with rhodium(I) dimers $[\text{Rh}(\text{COD})\text{Cl}]_2$ (COD = 1,5-cyclooctadiene) and $[\text{Rh}(\text{CO})_2\text{Cl}]_2$ investigated. Dinuclear complexes were isolated in both cases, where the calix[4]arene-based NHC ligand adopts a bridging μ^2 -coordination mode, and in one case characterised in the solid-state by X-ray diffraction. Using instead an isolated and well-defined (mononuclear) silver transfer agent, generated by reaction of **1.2HI** with Ag_2O in the presence of a halide extractor, reactions with $[\text{Rh}(\text{COD})\text{Cl}]_2$ and $[\text{Rh}(\text{CO})_2\text{Cl}]_2$ produced cationic dinuclear complexes bearing μ^2 -**1** and μ^2 -Cl bridging ligands. The structural formulation of the novel dinuclear adducts of **1** was aided through spectroscopic congruence with model complexes, containing monodentate 1,3-diisopropyl-4,5-dimethylimidazol-2-ylidene ($\text{I}^i\text{Pr}_2\text{Me}_2$).

Introduction

In addition to desirable donor properties, the structural versatility of N-heterocyclic carbenes (NHCs) has proven to be a major contributing factor in the widespread application of these ligands throughout organometallic chemistry and catalysis.¹ The root of this diversity lies in the numerous and generally straightforward preparative procedures available for the construction of the respective NHC pro-ligands; synthetic methodologies that have enabled access not only a plethora of monodentate ligands, but also an extensive range of polydentate variants.^{2,3}

As polydentate ligand scaffolds, calix[4]arenes are well suited building blocks with scope for functionalisation across the upper and/or lower rims of these 'bowl' shaped macromolecules.⁴ Despite extensive investigation of heteroatom-based donor systems, the coordination chemistry of NHC-functionalised calix[4]arenes is not well developed.⁵ 5,17-Difunctionalised examples, bearing NHC donors on opposite faces of the upper rim, are of particular interest for positioning bound metal centres across the macrocycle cavity. Well-defined complexes of these ligands are, however, limited to imidazol-2-

ylidene based **A–D** (Chart 1). Complexes **A** illustrate this principle well, positioning square planar palladium centres directly over the macrocycle cavity.⁶ The incorporation of a methylene spacer between the calix[4]arene rim and the NHC donor group in **B** results instead in unfavourable twisting of the donor groups that skews the bound metal centres to one side of the ligand, while in **C** and **D**, the cavity is pinched closed as

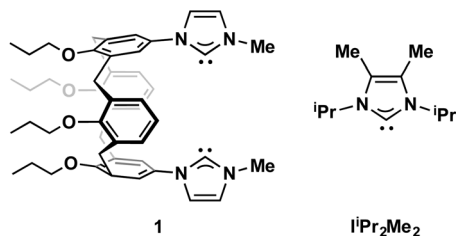

Chart 2 NHC systems of interest.

a consequence of the *cis*-coordination geometry of the metal centres.⁷ Closely related to **A**, phosphine-based systems **E** have also been described, where the ligand backbone enforces *trans*-coordination.^{8,9}

In this report the preparation and coordination chemistry of an upper rim functionalised calix[4]arene pro-ligand **1**·2HI are described (Chart 2). Through generation of the free NHC ligand (**1**) and use of transmetalation methodology, reactions with rhodium(I) dimers [Rh(COD)Cl]₂ (COD = 1,5-cyclooctadiene) and [Rh(CO)₂Cl]₂ lead to a range of dinuclear complexes containing either discrete or chloro-bridged metal fragments depending on the reagents employed. To help understand the influence of the calix[4]arene scaffold and corroborate the structural formulations of these species, the spectroscopic characteristics of complexes of **1** are contrasted with analogues containing the monodentate NHC ligand *i*Pr₂Me₂.¹⁰

Results and discussion

The synthesis of 5,17-(3-methyl-1-imidazole)-functionalised pro-ligand **1**·2HI was achieved through straightforward adaption of literature protocols for related *N*-butyl and *N*-isopropyl analogues, involving alkylation of **F** with methyl iodide and isolated in 84% yield (Scheme 1).¹¹ The known precursor **F** was obtained following a five step synthesis, starting from commercially available 4-*tert*-butylcalix[4]arene (*ca.* 2 weeks, 8% yield in our hands), giving an overall yield of 7% for the six step procedure.¹² The formation of the new bis(imidazolium) salt was fully corroborated through a combination of NMR spectroscopy, ESI-MS, combustion analysis and X-ray crystallography. In solution the pre-carbenic centre is characterized by ¹H and ¹³C resonances at δ 9.20 and δ 134.9 (CD₂Cl₂), respectively, while the mass spectrum showed a strong dication

signal centred at 377.2220 *m/z* (calcd 377.2224) with half-integer spacing. The solid-state structure features two independent but structurally similar dication that adopt distinctive 'pinched-cone' conformations, reflecting intra-charge repulsion between the imidazolium groups (C2...C8, 13.43(2) Å/ C102...C108, 13.09(2) Å; Fig. 1).¹³ In order to quantify this distortion, the angles between the least squares planes (Mpln) of opposing aryloxy groups $\theta_{\text{CALIX}}(\text{R})$, where R = the aryl *para* substituent and the sign reflects the relative disposition of the R substituents (+ve, outwards; -ve, inwards), have been measured. Using this approach distortion from an ideal *C*_{4v} symmetric 'cone' to *C*_{2v} symmetric 'pinched cone' conformation of the calix[4]arene skeleton was found to be most pronounced in the independent molecule shown in Fig. 1 with $\theta_{\text{CALIX}}(\text{NHC}\cdot\text{H}^+)/\theta_{\text{CALIX}}(\text{H}) = +80.8(2)/-19.3(2)^\circ$ ($\Delta\theta_{\text{CALIX}} = 100.1(4)^\circ$); the other is characterised by $\theta_{\text{CALIX}}(\text{NHC}\cdot\text{H}^+)/\theta_{\text{CALIX}}(\text{H}) = +86.4(2)/-2.8(2)^\circ$ ($\Delta\theta_{\text{CALIX}} = 89.2(4)^\circ$).

Deprotonation of **1**·2HI with strong hindered base K[O^{*t*}Bu] in C₆D₆ or d₈-THF at 293 K resulted in quantitative formation of the free carbene **1**, which was thoroughly characterised *in situ* using NMR spectroscopy. The deprotonation was corroborated by the absence of the ¹H NCHN resonance and characteristically high frequency ¹³C resonance at δ 213.2

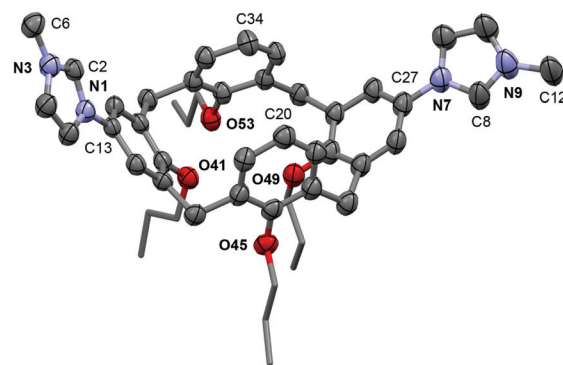

Fig. 1 Solid-state structure of **1**·2HI. Thermal ellipsoids for selected atoms drawn at the 30% probability level; only one of the two unique molecules shown (*Z* = 2); hydrogen atoms and anions are omitted for clarity. Selected bond lengths (Å) and angles (°): C2...C8, 13.43(2); $\angle\text{Mpln}(\text{C13}-\text{C18},\text{O41})-\text{Mpln}(\text{C27}-\text{C32},\text{O49})$, 80.8(2); $\angle\text{Mpln}(\text{C20}-\text{C25},\text{O45})-\text{Mpln}(\text{C34}-\text{C39},\text{O53})$, 19.3(2); C102...C108, 13.09(2); $\angle\text{Mpln}(\text{C113}-\text{C118},\text{O141})-\text{Mpln}(\text{C127}-\text{C132},\text{O149})$, 86.4(2); $\angle\text{Mpln}(\text{C120}-\text{C125},\text{O145})-\text{Mpln}(\text{C134}-\text{C139},\text{O153})$, 2.8(2).

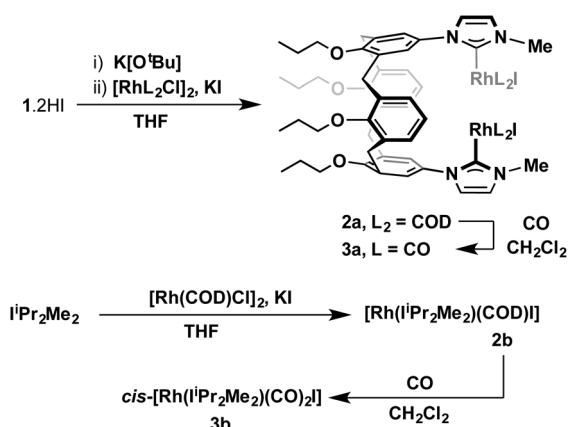

Scheme 1 Preparation and deprotonation of pro-ligand **1**·2HI.

(C_6D_6)/216.0 (d_8 -THF) of the carbenic centre.¹⁴ For comparison, the equivalent signal in 1Pr_2Me_2 is located at δ 212.7 (C_6D_6).¹⁰ Multiple attempts at isolating **1** from solution proved unsuccessful and instead it was generated *in situ* in subsequent studies.

Reactions of **1**, generated as described above, with rhodium(I) dimers $[Rh(COD)Cl]_2$ and $[Rh(CO)_2Cl]_2$ were explored in THF, using excess KI (*ca.* 10 equiv.) to avoid formation of mixed halide products. Using either 0.5 or 1 equiv. of rhodium precursor per ligand, the only well-defined species that could be identified were dinuclear complexes **2a** and **3a**, where **1** adopts a bridging μ^2 -coordination mode (Scheme 2). In this manner, rhodium-diene-based **2a** was obtained in good isolated yield of 53% following purification over alumina. Isolation of **3a**, however, proved to be very low yielding (*ca.* 17%) and in order to acquire a more meaningful quantity of **3a**,

alternative preparation from **2a** *via* diene displacement with CO (1 atm) in CH_2Cl_2 solution was required (quantitative conversion by 1H NMR spectroscopy, 37% isolated yield). Mononuclear analogues of these new complexes bearing 1Pr_2Me_2 , **2b** and **3b**, were readily obtained through direct adaptations of the aforementioned procedures (Scheme 2).

For both NHC ligands, the rhodium-diene complexes **2** were characterised in the solid-state by X-ray crystallography (Fig. 2). The conformation of the calix[4]arene backbone in **2a** is notable for a dramatic conformational inversion in comparison to the pro-ligand 1-2HI, that appears to be driven by a favourable (off-centre) π -stacking interaction between the imidazolylidene rings (Cnt-Cnt = 3.608(5) Å; $\Delta\theta_{CALIX} = -98.41(12)^\circ$, **2a**; 100.1(4)/89.2(4)°, 1-2HI), and pseudo C_2 symmetry. As expected for d^8 -metal complexes of this type, the rhodium centres adopt square planar coordination geometries in **2** and the associated metal-ligand bonding metrics are in line with related literature precedents.¹⁵ The similarity of the metal-NHC bonding characteristics in the new systems is apparent in both the solid-state (Rh-C = 2.021(3)/2.024(3) Å, **2a**; 2.021(3) Å, **2b**) and in solution by ^{13}C NMR spectroscopy [δ 180.4 ($^1J_{RhC} = 49$ Hz), **2a**; 178.4 ($^1J_{RhC} = 49$ Hz), **2b**]. The structures were fully corroborated in solution by 1H and ^{13}C NMR spectroscopy, with intact coordination of the diene ligands readily established by presence of alkene ^{13}C signals at *ca.* δ 95 ($^1J_{RhC} = 7$ Hz) and 72 ($^1J_{RhC} = 14$ Hz) displaying coupling to ^{103}Rh . Loss of C_s symmetry in the $\{Rh(COD)\}$ fragment and C_{2v} symmetry of the ligand **1** is observed on complexation, with C_2 symmetry evident on inspection of the 1H and $^{13}C\{^1H\}$ NMR spectra of **2a**. Moreover, a large difference in chemical shift is observed for the now inequivalent 1H resonances of the imidazolylidene functionalised aryl ring ($\Delta\delta = 2.03$), with the high frequency signal at δ 7.95 presumably a consequence of the close

Scheme 2 Reactions of **1** and 1Pr_2Me_2 with rhodium dimers.

Fig. 2 Solid-state structures of **2a** and **2b**. Thermal ellipsoids for selected atoms drawn at the 50% probability level; minor disordered components (two OⁿPr groups in **2a**, and hydrogen atoms omitted for clarity). Selected bond lengths (Å) and angles (°): **2a**: Rh1–I3, 2.6905(3); Rh1–Cnt(C5,C6), 2.089(3); Rh1–Cnt(C9,C10), 2.001(3); Rh1–C21, 2.021(3); Rh2–I4, 2.6934(3); Rh2–Cnt(C13,C14), 2.098(3); Rh1–Cnt(C17,C18), 1.990(4); Rh2–C27, 2.024(3); Rh1...Rh2, 8.5698(3); Cnt(C21–N25)–Cnt(C27–N31), 3.608(5); \angle Mpln(C33–C38,O61)–Mpln(C47–C52,O69), 22.35(6); \angle Mpln(C40–C45,O65)–Mpln(C54–C59,O73), 76.06(6); **2b**: Rh1–I2, 2.6729(2); Rh1–Cnt(C3,C4), 2.109(2); Rh1–Cnt(C7,C8), 2.00(3); Rh1–C11, 2.021(3).

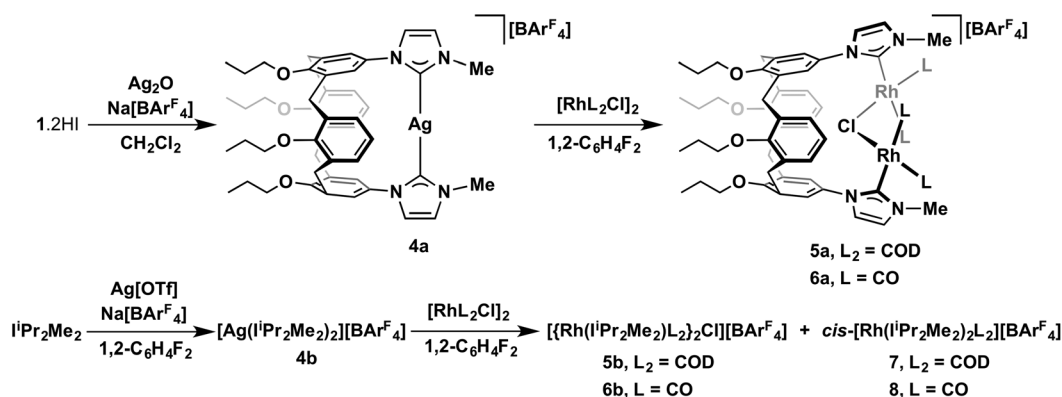

proximity of the halogen atom (*cf.* $C-H\cdots I = 4.139(3)/4.295(3)$ Å observed in the solid-state and δ 6.61 for 1·2HI), as previously noted in a related calix[4]arene-based system.^{5b} Combined, these NMR data of **2a** are consistent with retention of solid-state structure in solution.

Although, we have so far been unable to grow suitable samples of **3** for structural elucidation by X-ray crystallography, the solution data points strongly to equivalent structural formations as **2**. For instance, the relative *cis*-configuration of the carbonyl ligands was established through observation of two bands in the respective IR spectra ($\nu(CO) = 2071, 2002$, **3a**; 2072, 1998 cm^{-1} , **3b**) and two distinct high frequency doublet resonances in the $^{13}C\{^1H\}$ NMR spectra [δ 188.4 ($^1J_{RhC} = 54$ Hz), 181.6 ($^1J_{RhC} = 78$ Hz), **3a**; 188.7 ($^1J_{RhC} = 53$ Hz), 182.7 ($^1J_{RhC} = 78$ Hz), **3b**]. 1H and $^{13}C\{^1H\}$ NMR spectra of **3a** also exhibit C_2 symmetry. In comparison to **2**, the carbenic resonances are notable for a shift to lower frequency by *ca.* 10 ppm and there is a reduction in the magnitude of the coupling to ^{103}Rh [δ 171.5 ($^1J_{RhC} = 44$ Hz), **3a**; 166.8 ($^1J_{RhC} = 41$ Hz), **3b**].

To further explore the coordination chemistry of **1**, we sought to utilise widely employed transmetalation methodology based on silver transfer agents.^{1c,16} To this end, 1·2HI was reacted with a slight excess of Ag_2O in the presence of Na[BAR^F_4] ($Ar^F = 3,5-C_6H_3(CF_3)_2$), as a halide extractor, resulting in chelation of **1** and subsequent isolation of **4a** in 73% yield (Scheme 3). The structural formulation of the new silver(I) complex was readily established in solution through a combination of 1H and ^{13}C NMR spectroscopy and ESI-MS. The 1H NMR spectrum of isolated **4a** shows C_{2v} symmetry, with the *N*-methyl signal located to lower frequency than found in the pro-ligand (δ 3.80 vs. 4.17). A strong parent ion is observed by ESI-MS in positive ion mode at 859.3340 m/z (calcd 859.3347 m/z) with a correct isotope pattern. Moreover the cation : [BAR^F_4] ratio was verified by integration of 1H NMR data and elemental analysis. The $^{13}C\{^1H\}$ NMR spectrum is notable for the carbenic signal at δ 180.7 that shows coupling to both ^{109}Ag ($^1J_{AgC} = 211$ Hz) and ^{107}Ag ($^1J_{AgC} = 183$ Hz); the chemical shift and relative magnitudes of these coupling constants are in good agreement with literature values.^{16a} Interrogation of single crystals of **4a** by X-ray diffraction provides further evidence to the

mononuclear formulation of **4a** in solution, revealing a distorted linear geometry of the silver cation [$C2-Ag1-C8 = 171.00$ (14°) and essentially equivalent $Ag-C$ bond lengths ($Ag1-C2, 2.085(4)$; $Ag1-C8, 2.083(4)$; Fig. 3). The biscarbene silver complex of $I^1Pr_2Me_2$ bearing the tetrafluoroborate counter anion [$Ag(I^1Pr_2Me_2)_2$][BF_4] **G** has previously been prepared,¹⁷ however, for comparison the analogue bearing the [BAR^F_4] $^-$ counter anion **4b** was generated *in situ* through reaction of $Ag[OTf]$, Na[BAR^F_4] and 2 equiv. $I^1Pr_2Me_2$ in 1,2- $C_6H_4F_2$. The solid-state structure of **4b** is notable for a significantly more orthogonal orientation of the NHC ligands in comparison to **4a** and **G** [*e.g.* $|N6-C2-C8-N12| = 3.7(5)^\circ$, **4a**; $|N3-C2-C15-N19| = 77.0(5)^\circ$, **4b**; $|N-C-C-N| = 20.6(6)^\circ$, **G**]. The near coplanar disposition of the NHC donors in **4a** is fully in line with expectation, and readily attributed to the calix[4]arene scaffold [$\Delta\theta_{CALIX} = -96.4(2)^\circ$], while the conformational differences in **4b/G** are presumably attributed to crystal packing effects, induced by disparate anion sizes, and enabled through low-energy $Ag-NHC$ bond rotation. The $Ag-C$ bond lengths are all within experimental error [$2.085(4)/2.083(4)$ Å, **4a**; $2.093(4)/2.092(4)$ Å, **4b**; $2.078(11)$ Å, **G**], although we note an apparent trend of bond length contraction for **4a** in comparison to **4b** and that this parameter was not determined with high precision for **G**.

Silver complex **4a** acts as an effective carbene transfer agent, resulting in the formation of dinuclear complexes **5a** and **6a** bearing both μ^2-1 and μ^2-Cl ligands on reaction with 1 equiv. of [$Rh(COD)Cl$] $_2$ and [$Rh(CO)_2Cl$] $_2$, respectively, in 1,2- $C_6H_4F_2$ – established by NMR spectroscopy and ESI-MS. The reaction stoichiometries were maintained when using 0.5 equiv. of rhodium dimer instead, indicating selective formation **5a** and **6a**. Both dinuclear products were obtained in moderate isolated yields (63% and 59% respectively) and were difficult to fully purify, due to limited solution stability. Aided by comparison to **2a/3a** and supported through preparation of direct $I^1Pr_2Me_2$ analogues (*vide infra*), the formulation of the structures of **5a/6a** was achieved through a combination of 1H , ^{13}C NMR and IR spectroscopy, ESI-MS and in the case of **5b** a low resolution X-ray structure (Fig. 4). The ESI-MS in particular evidenced formation of these dinuclear monocationic species, with parent cation signals at 1209.3986 (calcd 1209.3973) and

Scheme 3 Preparation and transmetalation reactions of silver NHC complexes.

Fig. 3 Solid-state structures of **4a** and **4b**. Thermal ellipsoids for selected atoms drawn at the 30% probability level; minor disordered components (four OⁿPr groups in **4a**), hydrogen atoms and anions omitted for clarity. Selected bond lengths (Å) and angles (°): **4a**: Ag1–C2, 2.085(4); Ag1–C8, 2.083(4); C2–Ag1–C8, 171.00(14); ∠Mpln(C14–C19,O42)–Mpln(C28–C33,O50), 1.01(8); ∠Mpln(C21–C26,O46)–Mpln(C35–C40,O54), 97.44(10); **4b**: Ag1–C2, 2.093(4); Ag1–C15, 2.092(4); C2–Ag1–C15, 176.81(15).

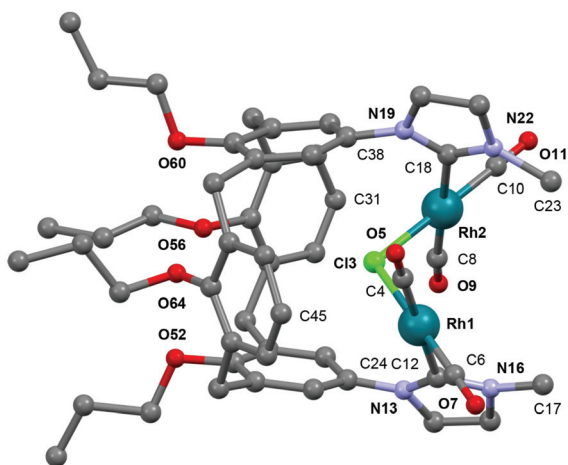

Fig. 4 Solid-state structure of **6a** (ball and stick, poor quality data). Minor disordered component (CO), hydrogen atoms and anion omitted for clarity. Selected bond lengths (Å) and angles (°): Rh1–Cl3, 2.353(5); Rh2–Cl3, 2.360(5); Rh1...Rh2, 3.861(3); Rh1–Cl3–Rh2, 110.0(3); ∠Mpln(C24–C29,O52)–Mpln(C38–C43,O60), 9.7(3); ∠Mpln(C31–C36,O56)–Mpln(C45–C50,O64), 92.8(4).

1105.1680 (calcd 1105.1891) m/z , respectively for **5a** and **6a**, with correct isotope patterns and integer mass spacing. Moreover the cation : [BAR^F₄] ratio was verified by integration of ¹H NMR data. In both cases, single carbene resonances [δ 176.9 (¹J_{RhC} = 50 Hz), **5a**; 168.1 (¹J_{RhC} = 43 Hz), **6a**] with very similar chemical shifts and ¹J_{RhC} coupling constants to the respective neutral analogues [δ 180.4 (¹J_{RhC} = 49 Hz), **2a**; 171.5 (¹J_{RhC} = 44 Hz), **3a**], alongside ¹⁰³Rh coupled alkene and carbonyl signals, were observed by ¹³C NMR spectroscopy. For **6a** both carbonyl stretching bands are perturbed (as expected) to higher frequency relative to neutral **3a** [ν (CO) = 2083, 2016, **6a**; 2071, 2002 cm⁻¹, **3a**]. Bond connectivity and conformational features

of **6a** were established through X-ray diffraction, using a poor quality crystalline sample [$R_1 = 0.2744$, $I \geq 2\sigma(I)$]. The data nevertheless can affirm the structural formulation, with a reduced pinching of calix[4]arene core [$\Delta\theta_{\text{CALIX}} = -83.1(7)^\circ$] relative to **2a** [$\Delta\theta_{\text{CALIX}} = -98.41(12)^\circ$] and **4a** [$\Delta\theta_{\text{CALIX}} = -96.4(2)^\circ$].

Starting from the known precursors [Rh(¹Pr₂Me₂)(COD)Cl] and [Rh(¹Pr₂Me₂)(CO)₂Cl], the new μ^2 -Cl bridged dinuclear complexes **5b** and **6b** were readily prepared by partial halide extraction using 0.5 equiv. of Na[BAR^F₄] in CH₂Cl₂ (Scheme 4). These structurally simple and fully characterised species (solution and solid-state, Fig. 5) help verify the formulation of **5a** and **6a**, with excellent agreement of the related spectroscopic data e.g. carbene ¹³C signals of **5** [δ 176.9 (¹J_{RhC} = 50 Hz), **5a**; 175.6 (¹J_{RhC} = 50 Hz), **5b**] and carbonyl stretching bands of **6** [ν (CO) = 2083, 2016, **6a**; 2090, 2019 cm⁻¹, **6b**] – see Experimental section for full details. Although iridium NHC and rhodium phosphine examples have been reported, there are no proceeding crystallographically characterised examples of rhodium NHC complexes featuring a single otherwise unsupported bridging halogen atom to the best of our knowledge.¹⁸ Conformational differences, associated with the relative orientation of the NHC ligands about the Rh–Cl–Rh bridge, are evident when comparing the solid-state structures of **6a** (*anti*) **5b** (*syn*) **6b** (*anti*); ¹H and ¹³C NMR data for **5a** and **6a** are most consistent with C₂ symmetry and *anti*-configurations in solution. Contrasting reactions of **4a** and **4b**, the calix[4]arene scaffold promotes the selective formation of dinuclear com-

Scheme 4 Preparation of dinuclear complexes **5b** and **6b**.

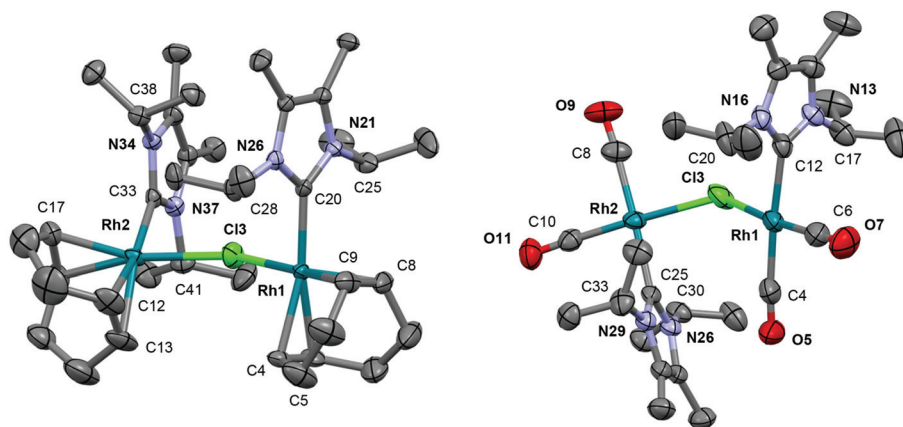

Fig. 5 Solid-state structures of **5b** and **6b**. Thermal ellipsoids drawn at the 50% probability level; minor disordered components (two ⁱPr groups in **6b**), hydrogen atoms, solvent (**6a**), and anions omitted for clarity. Selected bond lengths (Å) and angles (°): **5b**: Rh1–Cl3, 2.3988(9); Rh1–Cnt(C4,C5), 2.092(5); Rh1–Cnt(C8,C9), 1.974(4); Rh1–C20, 2.025(3); Rh2–Cl3, 2.4067(9); Rh2–Cnt(C12,C13), 2.101(4); Rh2–Cnt(C16,C17), 1.972(4); Rh2–C33, 2.022(3); Rh1–Cl3–Rh2, 144.13(4); **6b**: Rh1–Cl3, 2.4045(9); Rh1–C4, 1.915(4); Rh1–C6, 1.833(4); Rh1–C22, 2.069(3); Rh2–Cl3, 2.3987(9); Rh2–C8, 1.920(4); Rh2–C10, 1.817(4); Rh2–C25, 2.069(3); Rh1–Cl3–Rh2, 122.26(4).

plexes. For instance, when **4b** is reacted with 1 equiv. of $[\text{Rh}(\text{COD})\text{Cl}]_2$ or $[\text{Rh}(\text{CO})_2\text{Cl}]_2$ in 1,2- $\text{C}_6\text{H}_4\text{F}_2$ mixtures of **5b**/*cis*- $[\text{Rh}(\text{i}^i\text{Pr}_2\text{Me}_2)_2(\text{COD})][\text{BAR}^{\text{F}}_4]$ **7** (2 : 1) and **6b**/*cis*- $[\text{Rh}(\text{i}^i\text{Pr}_2\text{Me}_2)_2(\text{CO})_2][\text{BAR}^{\text{F}}_4]$ **8** (5 : 2) are the organometallic species produced as determined by ^1H NMR spectroscopy (Scheme 3) – with the structures of **7** and **8** verified by independent synthesis and full characterisation, including in the solid-state by X-ray diffraction (see experimental for full details).

Summary

Using both free carbene and transmetalation methodologies the coordination chemistry of bis(imidazolium) pro-ligand 1·2HI with rhodium(i) dimers $[\text{Rh}(\text{COD})\text{Cl}]_2$ and $[\text{Rh}(\text{CO})_2\text{Cl}]_2$ has been investigated, culminating in the isolation of neutral and cationic dinuclear complexes where the calix[4]arene based-NHC is bound in a μ^2 -coordination mode. These dinuclear complexes have been well characterised in solution using NMR spectroscopy, IR spectroscopy (CO derivatives) and ESI-MS (cationic complexes), and their structural formulation corroborated through excellent agreement of these data with that associated with simpler model complexes containing instead $\text{i}^i\text{Pr}_2\text{Me}_2$. Structures determined through X-ray diffraction highlight the flexibility of the calix[4]arene ligand scaffold, which undergoes significant conformational change driven by charge repulsion (bis-cationic 1·2HI), π -stacking of the imidazolylidene rings (**2a**), *trans*-coordination to silver (**4a**), or presence of a bridging μ^2 -Cl ligand (**6a**).

Experimental

General considerations

All manipulations were performed under an atmosphere of argon, using Schlenk and glove box techniques unless otherwise

stated. Glassware was oven dried at 150 °C overnight and flamed under vacuum prior to use. Anhydrous CH_2Cl_2 , Et_2O , and pentane (<0.005% H_2O) were purchased from ACROS or Aldrich and freeze–pump–thaw degassed three times before being placed under argon. THF was dried over sodium/benzophenone, vacuum distilled, and freeze–pump–thaw degassed three times before being placed under argon. 1,2- $\text{C}_6\text{H}_4\text{F}_2$ was stirred over neutral alumina, filtered, dried over CaH_2 , vacuum distilled, and freeze–pump–thaw degassed three times before being placed under argon. C_6D_6 was dried over Na, vacuum distilled, and freeze–pump–thaw degassed three times before being placed under argon. d_8 -THF was dried over 3 Å molecular sieves and freeze–pump–thaw degassed three times before being placed under argon. 5,17-bis(imidazolium)-25,26,27,28-tetrapropoxycalix[4]arene (**F**),¹² $\text{i}^i\text{Pr}_2\text{Me}_2$,¹⁰ $[\text{Rh}(\text{COD})\text{Cl}]_2$,¹⁹ $[\text{Rh}(\text{CO})_2\text{Cl}]_2$,²⁰ $\text{Na}[\text{BAR}^{\text{F}}_4]$,²¹ $[\text{Rh}(\text{i}^i\text{Pr}_2\text{Me}_2)(\text{COD})\text{Cl}]$,²² and *cis*- $[\text{Rh}(\text{i}^i\text{Pr}_2\text{Me}_2)(\text{CO})_2\text{Cl}]$ ²² were synthesised using literature protocols. All other solvents and reagents are commercial products and were used as received. NMR spectra were recorded on Bruker AV spectrometers at 298 K unless otherwise stated. ^1H NMR spectra recorded in 1,2- $\text{C}_6\text{H}_4\text{F}_2$ were referenced using the highest intensity peak of the highest (δ 6.865) frequency fluoroarene multiplet. $^{13}\text{C}\{^1\text{H}\}$ NMR spectra recorded in 1,2- $\text{C}_6\text{H}_4\text{F}_2$ were referenced using an internal sealed capillary of C_6D_6 . Chemical shifts are quoted in ppm and coupling constants in Hz. IR spectra were recorded on a PerkinElmer Spectrum One FT-IR spectrometer at 293 K. ESI-MS analyses were recorded on Bruker Maxis Impact instrument. Microanalyses were performed by Stephen Boyer at London Metropolitan University.

Preparation of 1·2HI

A solution of **F** (1.00 g, 1.38 mmol) was stirred with iodomethane (0.84 mL, 13.8 mmol) in THF (30 mL) at 70 °C for

14 hours. The product was isolated by filtration following addition of Et₂O (*ca.* 20 mL), washed with Et₂O (2 × 20 mL) and dried *in vacuo*. Yield = 1.17 g (84%, fine off-white powder).

¹H NMR (CD₂Cl₂, 400 MHz): δ 9.20 (br, 2H, NCHN), 8.04 (t, ³J_{HH} = 1.8, 2H, imid.), 7.23 (d, ³J_{HH} = 7.5, 4H, Ar), 7.05 (t, ³J_{HH} = 7.5, 2H, Ar), 6.72 (t, ³J_{HH} = 1.8, 2H, imid.), 6.61 (s, 4H, Ar), 4.54 (d, ²J_{HH} = 13.5, 4H, ArCH₂Ar), 4.17 (s, 6H, NCH₃), 4.03–4.09 (m, 4H, OCH₂), 3.74 (t, ³J_{HH} = 6.8, 4H, OCH₂), 3.28 (d, ²J_{HH} = 13.5, 4H, ArCH₂Ar), 1.87–2.06 (m, 8H, CH₂CH₃), 1.12 (t, ³J_{HH} = 7.4, 6H, CH₂CH₃), 0.93 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃). ¹³C{¹H} NMR (CD₂Cl₂, 101 MHz): δ 157.5 (s, COCH₂), 157.3 (s, COCH₂), 137.7 (s, Ar{CCH₂}), 135.7 (s, Ar{CCH₂}), 134.9 (s, NCHN), 130.2 (s, Ar), 129.2 (s, Ar{CN}), 125.6 (s, imid.), 124.4 (s, Ar), 120.8 (s, Ar), 119.9 (s, imid.), 78.1 (s, OCH₂), 77.4 (s, OCH₂), 37.8 (s, NCH₃), 31.4 (s, ArCH₂Ar), 23.9 (s, CH₂CH₃), 23.5 (s, CH₂CH₃), 10.9 (s, CH₂CH₃), 10.2 (s, CH₂CH₃). ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 377.2220 *m/z*, [M]²⁺ (calcd 377.2224 *m/z*). Anal. Calcd For C₄₈H₅₈I₂N₄O₄ (1008.81 g mol⁻¹): C, 57.13; H, 5.80; N, 5.55. Found: C, 56.88; H, 6.00; N, 5.55.

Deprotonation of 1-2HI

A suspension of 1-2HI (10.2 mg, 0.0101 mmol) and K[O^tBu] (3.1 mg, 0.0276 mmol) in d₈-THF (0.5 mL) was agitated and sonicated for several minutes inside a sealed J. Young's NMR tube. Analysis by NMR spectroscopy indicated quantitative formation of **1** with the concomitant formation of ^tBuOH (δ_H 5.33, OH; 1.15, CH₃; δ_C 68.1, CCH₃; 31.6, CH₃). The reaction was repeated in C₆D₆ with the same outcome. The ¹H NMR spectra remained unchanged on standing at 293 K for 24 h in both cases.

¹H NMR (d₈-THF, 500 MHz): δ 7.41 (s, 4H, Ar), 7.24 (d, ³J_{HH} = 1.6, 2H, imid.), 6.94 (d, ³J_{HH} = 1.6, 2H, imid.), 6.40 (d, ³J_{HH} = 7.5, 4H, Ar), 6.31 (app t, 2H, *J* = 8, Ar), 4.51 (d, ²J_{HH} = 13.1, 4H, ArCH₂Ar), 4.00–4.04 (m, 4H, OCH₂), 3.76–3.79 (m, 4H, OCH₂), 3.76 (s, 6H, NCH₃), 3.20 (d, ²J_{HH} = 13.1, 4H, ArCH₂Ar), 1.99–2.07 (m, 4H, CH₂CH₃), 1.92–1.99 (m, 4H, CH₂CH₃), 1.10 (t, ³J_{HH} = 7.4, 6H, CH₂CH₃), 0.98 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃). ¹³C{¹H} NMR (d₈-THF, 126 MHz): δ 216.0 (s, NCN), 156.7 (s, COCH₂), 156.3 (s, COCH₂), 137.9 (s, Ar{CN}), 137.6 (s, Ar{CCH₂}), 134.5 (s, Ar{CCH₂}), 128.9 (s, Ar), 123.1 (s, Ar), 121.6 (s, Ar), 121.1 (s, imid.), 118.1 (s, imid.), 77.9 (s, OCH₂), 77.7 (s, OCH₂), 38.3 (s, NCH₃), 32.0 (s, ArCH₂Ar), 24.5 (s, CH₂CH₃), 24.2 (s, CH₂CH₃), 11.2 (s, CH₂CH₃), 10.7 (s, CH₂CH₃). ¹H NMR (C₆D₆, 500 MHz): δ 7.40 (s, 4H, Ar), 6.74 (d, ³J_{HH} = 7.5, 4H, Ar), 6.71 (br, 2H, imid.), 6.61 (t, ³J_{HH} = 7.5, 2H, Ar), 6.18 (br, 2H, imid.), 4.53 (d, ²J_{HH} = 13.2, 4H, ArCH₂Ar), 3.87 (t, ³J_{HH} = 7.6, 4H, OCH₂), 3.76 (t, ³J_{HH} = 7.4, 4H, OCH₂), 3.42 (s, 6H, NCH₃), 3.17 (d, ²J_{HH} = 13.3, 4H, ArCH₂Ar), 1.84–1.95 (m, 8H, CH₂CH₃), 0.93 (app. t, *J* = 7, 12H, CH₂CH₃). ¹³C{¹H} NMR (C₆D₆, 126 MHz): δ 213.2 (s, NCN), 156.7 (s, COCH₂), 155.5 (s, COCH₂), 137.1 (s, Ar{CN}), 136.4 (s, Ar{CCH₂}), 134.7 (s, Ar{CCH₂}), 128.8 (s, Ar), 123.0 (s, Ar), 121.5 (s, Ar), 120.1 (s, imid.), 117.8 (s, imid.), 77.1 (s, OCH₂), 77.0 (s, OCH₂), 37.8 (s, NCH₃), 31.6 (s, ArCH₂Ar), 23.7

(s, CH₂CH₃), 23.6 (s, CH₂CH₃), 10.6 (s, CH₂CH₃), 10.5 (s, CH₂CH₃).

Preparation of 2a

A solution of 1-2HI (99.7 mg, 0.0987 mmol) and K[O^tBu] (27.8 mg, 0.248 mmol) was stirred in THF (10 mL) for 1 hour then added to a flask charged with [Rh(COD)Cl]₂ (51.6 mg, 0.105 mmol) and KI (165.1 mg, 1.42 mmol). After a further hour the volatiles were removed *in vacuo*. The product was extracted with CH₂Cl₂ (2 × 10 mL) and purified over alumina (1 : 1 EtOAc/CH₂Cl₂, Air). Yield = 75.5 mg (53%, yellow powder).

¹H NMR (CD₂Cl₂, 400 MHz): δ 7.95 (d, ⁴J_{HH} = 2.8, 2H, Ar), 7.29–7.39 (m, 2H, Ar), 7.04–7.14 (m, 2H, Ar), 6.97 (t, ³J_{HH} = 7.4, 2H, Ar), 6.44 (d, ³J_{HH} = 2.0, 2H, imid.), 6.19 (d, ³J_{HH} = 2.0, 2H, imid.), 5.92 (d, ⁴J_{HH} = 2.8, 2H, Ar), 5.24–5.29 (m, 2H, COD{CH}), 4.92–5.09 (m, 2H, COD{CH}), 4.62 (d, ²J_{HH} = 13.3, 2H, ArCH₂Ar), 4.50 (d, ²J_{HH} = 13.5, 2H, ArCH₂Ar), 3.99–4.18 (m, 4H, OCH₂), 3.85 (s, 6H, NCH₃), 3.65–3.82 (m, 4H, OCH₂), 3.38 (d, ²J_{HH} = 13.4, 2H, ArCH₂Ar), 3.21–3.26 (m, 2H, COD{CH}), 3.19 (d, ²J_{HH} = 13.7, 2H, ArCH₂Ar), 2.29–2.39 (m, 2H, COD{CH}), 2.09–2.29 (m, 6H, COD{CH₂}), 1.97–2.09 (m, 4H, CH₂CH₃), 1.83–1.97 (m, 6H, CH₂CH₃ + COD{CH₂}), 1.58–1.79 (m, 4H, COD{CH₂}), 1.27–1.46 (m, 4H, COD{CH₂}), 1.15 (t, ³J_{HH} = 7.4, 6H, CH₂CH₃), 0.95 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃). ¹³C{¹H} NMR (CD₂Cl₂, 101 MHz): δ 180.4 (d, ¹J_{RhC} = 49, NCN), 158.2 (s, COCH₂), 155.0 (s, COCH₂), 137.0 (s, Ar{CCH₂}), 136.9 (s, Ar{CCH₂}), 134.9 (s, Ar{C}), 134.7 (s, Ar{C}), 134.3 (s, Ar{C}), 131.5 (s, Ar), 129.6 (s, Ar), 123.6 (s, Ar), 123.4 (s, imid.), 122.9 (s, Ar), 122.5 (s, imid.), 122.5 (s, Ar), 95.0 (d, ¹J_{RhC} = 7, COD{CH}), 95.0 (d, ¹J_{RhC} = 7, COD{CH}), 77.7 (s, OCH₂), 77.3 (s, OCH₂), 71.4 (d, ¹J_{RhC} = 14, 2 × COD{CH}), 39.1 (s, NCH₃), 33.9 (s, COD{CH₂}), 31.7 (s, CH₂), 31.4 (s, CH₂), 31.0 (s, CH₂), 30.7 (s, CH₂), 29.2 (s, COD{CH₂}), 23.8 (s, CH₂CH₃), 23.4 (s, CH₂CH₃), 11.3 (s, CH₂CH₃), 10.3 (s, CH₂CH₃). Anal. Calcd For C₆₄H₈₀I₂N₄O₄ (1428.24 g mol⁻¹): C, 53.79; H, 5.64; N, 3.92. Found: C, 53.71; H, 5.75; N, 4.04.

Preparation of 2b

A solution of I¹Pr₂Me₂ (61.2 mg, 0.336 mmol), [Rh(COD)Cl]₂ (166.1 mg, 0.337 mmol) and KI (1072.2 mg, 6.46 mmol) in THF (10 mL) was stirred for 1 hour. The volatiles were removed *in vacuo* and the product obtained after purification over silica (CH₂Cl₂, Air) and subsequent recrystallisation from CH₂Cl₂/pentane. Yield = 55.0 mg (31%, yellow crystals).

¹H NMR (CD₂Cl₂, 500 MHz): δ 5.97 (sept, ³J_{HH} = 7.1, 2H, NCH), 5.03–5.09 (m, 2H, COD{CH}), 3.50–3.57 (m, 2H, COD{CH}), 2.26–2.36 (m, 4H, COD{CH₂}), 2.16 (s, 6H, CCH₃), 1.87–1.98 (m, 2H, COD{CH₂}), 1.73–1.83 (m, 2H, COD{CH₂}), 1.56 (d, ³J_{HH} = 7.1, 6H, CHCH₃), 1.50 (d, ³J_{HH} = 7.1, 6H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 178.4 (d, ¹J_{RhC} = 49, NCN), 126.0 (s, CCH₃), 95.2 (d, ¹J_{RhC} = 7, COD{CH}), 71.5 (d, ¹J_{RhC} = 14, COD{CH}), 53.7 (s, NCH), 32.8 (s, COD{CH₂}), 30.0 (s, COD{CH₂}), 22.4 (s, CHCH₃), 21.4 (s, CHCH₃), 10.7 (s, CCH₃). Anal. Calcd for C₁₉H₃₂I₂N₂Rh (518.29 g mol⁻¹): C, 44.03; H, 6.22; N, 5.41. Found: C, 44.11; H, 6.14; N, 5.47.

Preparation of 3a

Method A: A solution of 1·2HI (102.1 mg, 0.101 mmol) and K[O^tBu] (28.9 mg, 0.258 mmol) was stirred in THF (10 mL) for 1 hour then added to a flask charged with [Rh(CO)₂Cl]₂ (40.7 mg, 0.105 mmol) and KI (165.4 mg, 0.996 mmol). After a further hour the volatiles were removed *in vacuo*. The product was extracted with CH₂Cl₂ (2 × 10 mL) and purified over alumina (1 : 1 Et₂O/CH₂Cl₂, Air). Yield = 22.4 mg (17%, yellow powder). **Method B:** A solution of 2a (121.2 mg, 0.0848 mmol) in CH₂Cl₂ (10 mL) was stirred under CO (1 atm) for 12 hours, resulting in a colour change from bright to pale yellow. The mixture was dried *in vacuo* and washed with pentane (3 × 5 mL). Yield = 42.1 mg (37%, yellow powder).

¹H NMR (CD₂Cl₂, 500 MHz): δ 7.26 (s, 2H, Ar), 7.02 (br, 4H, Ar), 6.82 (t, ³J_{HH} = 7.4, 2H, Ar), 6.77 (s, 2H, imid.), 6.46 (s, 2H, imid.), 6.41 (s, 2H, Ar), 4.51 (d, ²J_{HH} = 13.3, 2H, ArCH₂Ar), 4.48 (d, ²J_{HH} = 13.6, 2H, ArCH₂Ar), 3.80–4.09 (m, 8H, OCH₂), 3.77 (s, 6H, NCH₃), 3.24 (d, ²J_{HH} = 14.1, 2H, ArCH₂Ar), 3.22 (d, ²J_{HH} = 14.1, 2H, ArCH₂Ar), 1.79–2.16 (m, 8H, CH₂CH₃), 1.03–1.13 (m, 6H, CH₂CH₃), 0.92–1.03 (m, 6H, CH₂CH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 188.4 (d, ¹J_{RhC} = 54, CO), 181.6 (d, ¹J_{RhC} = 78, CO), 171.5 (d, ¹J_{RhC} = 44, NCN), 157.5 (s, COCH₂), 156.3 (s, COCH₂), 136.2, 136.1, 135.9, 135.6, 130.6, 129.4, 123.8, 123.4, 123.2, 122.8, 77.8 (OCH₂), 77.4 (OCH₂), 40.0 (s, NCH₃), 31.5 (br, ArCH₂Ar), 24.0 (CH₂CH₃), 23.7 (CH₂CH₃), 11.0 (s, CH₂CH₃), 10.4 (s, CH₂CH₃). Not all signals were unambiguously identified. IR (CH₂Cl₂, cm⁻¹): ν(CO) 2071, 2002. Anal. Calcd for C₅₂H₅₆I₂N₄O₈Rh₂ (1324.02 g mol⁻¹): C, 47.15; H, 4.26; N, 4.23. Found: C, 46.91; H, 4.12; N, 4.25.

Preparation of 3b

A solution of 2b (40.1 mg, 0.0774 mmol) in CH₂Cl₂ (10 mL) was placed under an atmosphere of CO (1 atm) for 2 hours. The volatiles were removed *in vacuo* to afford the product, which was washed with pentane (3 × 10 mL) and dried thoroughly under vacuum. Yield = 21.4 mg (59%, fine yellow powder).

¹H NMR (CD₂Cl₂, 500 MHz): δ 5.26 (sept, ³J_{HH} = 7.1, 2H, NCH), 2.22 (s, 6H, CCH₃), 1.501 (d, ³J_{HH} = 7.1, 6H, CHCH₃), 1.496 (d, ³J_{HH} = 2.7, 6H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 188.7 (d, ¹J_{RhC} = 53, CO), 182.7 (d, ¹J_{RhC} = 78, CO), 166.8 (d, ¹J_{RhC} = 41, NCN), 127.2 (s, CCH₃), 54.3 (s, CHCH₃), 22.2 (s, CHCH₃), 21.1 (s, CHCH₃), 10.7 (s, CCH₃). IR (CH₂Cl₂, cm⁻¹): ν(CO) 2072, 1998. Anal. Calcd for C₁₃H₂₀I₂N₂O₂Rh (466.12 g mol⁻¹): C, 33.50; H, 4.33; N, 6.01. Found: C, 33.41; H, 4.25; N, 6.03.

Preparation of 4a

A suspension of 1·2HI (79.5 mg, 0.0788 mmol), Ag₂O (20.0 mg, 0.0862 mmol) and Na[BAR^F₄] (69.0 mg, 0.0778 mmol) in CH₂Cl₂ (20 mL) was sonicated periodically over two hours. The solution was filtered and the solvent was removed *in vacuo* to afford the product. Yield = 100.0 mg (73%, white crystals).

¹H NMR (400 MHz, CD₂Cl₂): δ 7.72–7.76 (m, 8H, Ar^F), 7.57 (br, 4H, Ar^F), 7.10 (d, ³J_{HH} = 7.4, 4H, Ar), 6.92 (d, ³J_{HH} = 1.7, 2H, imid.), 6.85 (t, ³J_{HH} = 7.5, 2H, Ar), 6.81 (d, ³J_{HH} = 1.7, 2H, imid.), 6.40 (s, 4H, Ar), 4.57 (d, ²J_{HH} = 12.8, 4H, ArCH₂Ar), 4.10–4.22 (m, 4H, OCH₂), 3.80 (s, 6H, NCH₃), 3.74 (t, ³J_{HH} = 7.1, 4H, OCH₂), 3.24 (d, ²J_{HH} = 12.8, 4H, ArCH₂Ar), 2.10–2.21 (m, 4H, CH₂CH₃), 1.99 (app. sex., J = 7, 4H, CH₂CH₃), 1.12 (t, ³J_{HH} = 7.4, 6H, CH₂CH₃), 0.98 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃). ¹³C{¹H} NMR (CD₂Cl₂, 101 MHz): δ 180.7 (two coincident d, ¹J_{109AgC} = 211, ¹J_{107AgC} = 183, NCN), 162.3 (q, ¹J_{BC} = 50.5, Ar^F), 157.8 (COCH₂), 156.7 (s, COCH₂), 136.5 (s, 2 × Ar{C}), 135.4 (s, Ar^F), 134.3 (s, Ar{C}), 129.4 (qq, ²J_{FC} = 32, ³J_{BC} = 3, Ar^F), 129.3 (s, Ar), 118.0 (sept, ³J_{FC} = 4, Ar^F), 126.4 (s, Ar), 125.2 (q, ¹J_{FC} = 272, Ar^F), 124.7 (d, ³J_{AgC} = 6, imid.), 123.4 (s, Ar), 121.9 (d, ³J_{AgC} = 6, imid.), 118.0 (sept, ³J_{FC} = 4, Ar^F), 78.7 (s, OCH₂), 77.2 (s, OCH₂), 38.8 (d, ³J_{AgC} = 3, NCH₃), 31.4 (s, ArCH₂Ar), 24.0 (s, CH₂CH₃), 23.5 (s, CH₂CH₃), 11.0 (s, CH₂CH₃), 10.1 (s, CH₂CH₃). ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 859.3340 m/z, [M]⁺ (calcd 859.3347 m/z). Anal. Calcd For C₈₀H₆₈AgBF₂₄N₄O₄ (1724.09 g mol⁻¹): C, 55.73; H, 3.98; N, 3.25. Found: C, 55.85; H, 4.08; N, 3.33.

In situ reactions of 4b

A suspension of I¹Pr₂Me₂ (9.9 mg, 0.0549 mmol), Ag[OTf] (7.2 mg, 0.0277 mmol) and Na[BAR^F₄] (24.0 mg, 0.0271 mmol) in difluorobenzene (0.5 mL) was agitated for several minutes. Analysis *in situ* by NMR spectroscopy indicated quantitative formation of 4b (data below). Solutions of 4b, prepared in this way, were then filtered onto either [Rh(COD)Cl]₂ (13.6 mg, 0.0276 mmol) or [Rh(CO)₂Cl]₂ (10.8 mg, 0.0278 mmol), resulting in the formation of 5b : 7 (2 : 1) and 6b/8 (5 : 2).

¹H NMR (1,2-C₆H₄F₂, 500 MHz): δ 8.11–8.13 (m, 8H, Ar^F), 7.49 (br, 4H, Ar^F), 4.20 (sept, ³J_{HH} = 6.8, 4H, NCH), 1.87 (s, 12H, CCH₃), 1.31 (d, ³J_{HH} = 6.8, 24H, CHCH₃). ¹³C{¹H} NMR (1,2-C₆H₄F₂, 126 MHz): δ 162.5 (q, ¹J_{BC} = 50, Ar^F), 135.1 (s, Ar^F), 129.7 (qq, ²J_{FC} = 32, ³J_{BC} = 3, Ar^F), 124.9 (q, ¹J_{FC} = 272, Ar^F), 124 (obscured, CCH₃), 117.6 (sept, ³J_{FC} = 4, Ar^F), 50.1 (s, NCH), 23.3 (s, CHCH₃), 8.1 (s, CCH₃). The carbene resonance was not located. ¹⁹F{¹H} NMR (1,2-C₆H₄F₂, 282 MHz): δ -62.25 (Ar^F). No signal for [OTf]⁻ detected. ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 467.2297 m/z, [M]⁺ (calcd 467.2298 m/z).

Preparation of 5a

A solution of 4a (29.9 mg, 0.0173 mmol) and [Rh(COD)Cl]₂ (9.4 mg, 0.0191 mmol) in 1,2-C₆H₄F₂ (0.5 mL) was stirred for 1 hour with the exclusion of light. The solvent was removed *in vacuo* and the resulting crude material washed with pentane and dried *in vacuo*. Yield = 22.3 mg (63%, yellow powder). The product was characterised *in situ*, although has limited stability in solution.

¹H NMR (1,2-C₆H₄F₂/C₆D₆, 500 MHz): δ 8.09–8.15 (m, 8H, Ar^F), 7.49 (br, 4H, Ar^F), 5.44 (br, 2H, COD{CH}), 5.38 (br, 2H, COD{CH}), 4.58 (d, ²J_{HH} = 13.6, 2H, ArCH₂Ar), 4.49 (d, ²J_{HH} = 13.6, 2H, ArCH₂Ar), 4.20 (s, 6H, NCH₃), 3.96–4.24 (m), 3.67–3.76 (m), 3.55–3.63 (m), 3.49–3.55 (m), 3.46 (d, ²J_{HH} = 13.6, 2H, ArCH₂Ar), 3.23–3.33 (m), 3.09 (d, ²J_{HH} = 13.6, 2H,

ArCH₂Ar), 1.35–2.50 (m, CH₂), 1.03 (t, ³J_{HH} = 6.9, 6H, CH₂CH₃), 0.85 (t, ³J_{HH} = 6.9, 6H, CH₂CH₃), 0.7–1.1 (m, COD{CH₂}). Not all signals unambiguously assigned and some signals obscured by solvent peak. ¹³C{¹H} NMR (1,2-C₆H₄F₂/C₆D₆, 126 MHz, selected signals only): δ 176.9 (d, ¹J_{RhC} = 50, NCN), 100.3 (br, COD{CH}), 96.4 (br, COD{CH}), 78.5 (d, ¹J_{RhC} = 14, COD{CH}), 71.8 (d, ¹J_{RhC} = 13, COD{CH}), 97.7 (d, ¹J_{RhC} = 7, COD{CH}), 70.2 (d, ¹J_{RhC} = 16, COD{CH}), 37.8 (s, NCH₃). ESI-MS (CH₃CN, 180 °C, 3 kV): positive ion: 1209.3986 *m/z*, [M]⁺ (calcd 1209.3973 *m/z*).

Preparation of 5b

A solution of [Rh(¹Pr₂Me₂)(COD)Cl] (23.6 mg, 0.0553 mmol) and Na[BAR^F₄] (24.5 mg, 0.0275 mmol) in CH₂Cl₂ (10 mL) was stirred for 1 hour. The solution was then filtered and layered with pentane to afford the product on diffusion. Yield = 32.0 mg (69%, yellow crystals).

¹H NMR (CD₂Cl₂, 500 MHz): δ 7.70–7.74 (m, 8H, Ar^F), 7.56 (br, 4H, Ar^F), 5.91 (sept, ³J_{HH} = 7.1, 4H, NCH), 4.75 (s, 4H, COD{CH}), 3.51 (s, 4H, COD{CH}), 2.22–2.36 (m, 8H, COD{CH₂}), 2.11 (s, 12H, CCH₃), 1.81–1.93 (m, 8H, COD{CH₂}), 1.57 (d, ³J_{HH} = 7.0, 12H, CHCH₃), 1.36 (d, ³J_{HH} = 7.0, 12H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 175.6 (d, ¹J_{RhC} = 50, NCN), 162.3 (q, ¹J_{BC} = 51, Ar^F), 135.4 (s, Ar^F), 129.4 (qq, ²J_{FC} = 31, ³J_{BC} = 3, Ar^F), 126.3 (s, CCH₃), 125.2 (q, ¹J_{FC} = 272, Ar^F), 118.0 (sept, ³J_{FC} = 4, Ar^F), 97.7 (d, ¹J_{RhC} = 7, COD{CH}), 70.2 (d, ¹J_{RhC} = 16, COD{CH}), 54.3 (s, NCH), 33.1 (s, COD{CH₂}), 29.1 (s, COD{CH₂}), 22.5 (s, CHCH₃), 22.2 (s, CHCH₃), 10.5 (s, CCH₃). ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 817.2872 *m/z*, [M]⁺ (calcd 817.2924 *m/z*). Anal. Calcd For C₇₀H₇₆BF₂₄N₄Rh₂Cl (1434.39 g mol⁻¹): C, 49.97; H, 4.56; N, 3.33. Found: C, 50.18; H, 4.52; N, 3.23.

Preparation of 6a

A solution of **4a** (32.0 mg, 0.0186 mmol) and [Rh(CO)₂Cl]₂ (7.8 mg, 0.0201 mmol) in 1,2-C₆H₄F₂ (10 mL) was stirred for one hour with the exclusion of light. The cloudy yellow solution was filtered, reduced to dryness and the resulting residue washed with pentane. Yield = 21.4 mg (31%, yellow powder). The product was characterised *in situ*, although has limited stability in solution.

¹H NMR (1,2-C₆H₄F₂/C₆D₆, 500 MHz): δ 8.11–8.15 (m, 8H, Ar^F), 7.49 (br, 4H, Ar^F), 4.52 (d, ²J_{HH} = 12.6, 2H, ArCH₂Ar), 4.51 (d, ²J_{HH} = 12.6, 2H, ArCH₂Ar), 4.05–4.19 (m, 2H, OCH₂), 3.88–3.99 (m, 2H, OCH₂), 3.84 (s, 6H, NCH₃), 3.51–3.65 (m, 4H, OCH₂), 3.18 (d, ²J_{HH} = 12.6, 2H, ArCH₂Ar), 3.15 (d, ²J_{HH} = 12.6, 2H, ArCH₂Ar), 2.11–2.23 (m, 4H, CH₂CH₃), 1.79–1.92 (m, 4H, CH₂CH₃), 0.94 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃), 0.93 (t, ³J_{HH} = 7.5, 6H, CH₂CH₃). Some signals obscured by solvent peak. ¹³C{¹H} NMR (1,2-C₆H₄F₂/C₆D₆, 126 MHz, selected signals only): δ 182.7 (d, ¹J_{RhC} = 53, CO), 181.0 (d, ¹J_{RhC} = 80, CO), 168.1 (d, ¹J_{RhC} = 43, NCN), 36.3 (s, NCH₃). ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 1105.1680 *m/z*, [M]⁺ (calcd 1105.1891 *m/z*). IR (CH₂Cl₂, cm⁻¹): ν(CO) 2083, 2016.

Preparation of 6b

A solution of [Rh(¹Pr₂Me₂)(CO)₂Cl] (26.5 mg, 0.709 mmol) and Na[BAR^F₄] (32.6 mg, 0.368 mmol) in CH₂Cl₂ (5 mL) was stirred for one hour. The solution was then filtered and layered with pentane to afford the product on diffusion. Yield = 37.1 mg (66%, yellow crystals).

¹H NMR (CD₂Cl₂, 400 MHz): δ 7.67–7.77 (m, 8H, Ar^F), 7.56 (br, 4H, Ar^F), 5.20 (sept, ³J_{HH} = 7.1, 4H, NCH), 2.18 (s, 12H, CCH₃), 1.55 (d, ³J_{HH} = 7.1, 12H, CHCH₃), 1.50 (d, ³J_{HH} = 7.0, 12H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 101 MHz): δ 185.4 (d, ¹J_{RhC} = 53, CO), 181.0 (d, ¹J_{RhC} = 84, CO), 162.3 (q, ¹J_{BC} = 50, Ar^F), 135.4 (s, Ar^F), 129.4 (qq, ²J_{FC} = 32, ³J_{BC} = 3, Ar^F), 128.0 (s, CCH₃), 125.2 (q, ¹J_{FC} = 272, Ar^F), 54.8 (s, NCH), 22.8 (s, CHCH₃)₂, 22.4 (s, CHCH₃)₂, (s, 10.6 CCH₃). The carbene resonance was not located. ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 713.0829 *m/z*, [M]⁺ (calcd 713.0843 *m/z*). IR (CH₂Cl₂, cm⁻¹): ν(CO) 2090, 2019. Anal. Calcd For C₅₈H₅₂BClF₂₄N₄O₄Rh₂Cl (1577.11 g mol⁻¹): C, 44.17; H, 3.32; N, 3.55. Found: C, 44.51; H, 3.57; N, 3.49.

Preparation of 7

A solution of ¹Pr₂Me₂ (50.8 mg, 0.282 mmol), [Rh(COD)Cl]₂ (34.3 mg, 0.0696 mmol) and Na[BAR^F₄] (123.4 mg, 0.139 mmol) was stirred in 1,2-C₆H₄F₂ (5 mL) for 2.5 h. The solution was then filtered and layered with pentane to afford the product on diffusion. Yield = 114.0 mg (56%, yellow crystals).

¹H NMR (CD₂Cl₂, 500 MHz): δ 7.71–7.75 (m, 8H, Ar^F), 7.56 (br, 4H, Ar^F), 5.56 (sept, ³J_{HH} = 7.1, 4H, NCH), 4.27 (s, 4H, COD{CH}), 2.31–2.40 (m, 4H, COD{CH₂}), 2.16 (s, 12H, CCH₃), 2.01–2.11 (m, 4H, COD{CH₂}), 1.55 (d, ³J_{HH} = 7.1, 12H, CHCH₃), 1.22 (d, ³J_{HH} = 7.1, 12H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 178.1 (d, ¹J_{RhC} = 55.8, NCN), 162.3 (q, ¹J_{BC} = 50, Ar^F), 135.4 (s, Ar^F), 129.4 (qq, ²J_{FC} = 32, ³J_{BC} = 3, Ar^F), 127.1 (s, CCH₃), 125.2 (q, ¹J_{FC} = 272, Ar^F), 118.0 (sept, ³J_{FC} = 4, Ar^F), 87.2 (d, ¹J_{RhC} = 8, COD{CH}), 54.5 (s, NCH), 31.8 (s, COD{CH}), 22.9 (s, CHCH₃), 21.6 (s, CHCH₃), 10.9 (s, CCH₃). ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 571.3215 *m/z*, [M]⁺ (calcd 571.3242 *m/z*). Anal. Calcd For C₆₂H₆₄BF₂₄N₄Rh (1434.39 g mol⁻¹): C, 51.96; H, 4.49; N, 3.90. Found: C, 52.05; H, 4.59; N, 3.93.

Preparation of 8

A solution of **7** (113.9 mg, 0.0794 mmol) in 1,2-C₆H₄F₂ (5 mL) was stirred under an atmosphere of CO (1 atm) for 24 hours. The solvent was removed *in vacuo* and the resulting crude material washed with pentane and recrystallised from CH₂Cl₂/pentane. Yield = 72.4 mg (66%, orange powder).

¹H NMR (CD₂Cl₂, 500 MHz): δ 7.71–7.75 (m, 8H, Ar^F), 7.56 (br, 4H, Ar^F), 5.05 (sept, ³J_{HH} = 7.1, 4H, NCH), 2.20 (s, 12H, CCH₃), 1.46 (d, ³J_{HH} = 7.1, 12H, CHCH₃), 1.19 (d, ³J_{HH} = 7.1, 12H, CHCH₃). ¹³C{¹H} NMR (CD₂Cl₂, 126 MHz): δ 186.9 (d, ¹J_{RhC} = 57, CO), 168.2 (d, ¹J_{RhC} = 47, NCN), 162.3 (q, ¹J_{BC} = 50, Ar^F), 135.3 (s, Ar^F), 129.4 (qq, ²J_{FC} = 32, ³J_{BC} = 3, Ar^F), 128.2 (s, CCH₃), 125.2 (q, ¹J_{FC} = 272, Ar^F), 118.0 (sept, ³J_{FC} = 4, Ar^F), 55.3 (s, NCH), 22.0 (s, CHCH₃), 21.1 (s, CHCH₃), 10.9 (s, CCH₃).

ESI-MS (CH₃CN, 180 °C, 3 kV) positive ion: 519.2249 *m/z* [M]⁺ (calcd 520.2201 *m/z*). **IR** (CH₂Cl₂, cm⁻¹): ν(CO) 2077, 2018. **Anal.** Calcd For C₅₆H₅₂BF₂₄N₄Rh (1382.29 g mol⁻¹): C, 48.64; H, 3.79; N, 4.05. Measured: C, 48.51; H, 3.63; N, 4.15.

Crystallography

Full details about the collection, solution and refinement are documented in the CIF, which have been deposited with the Cambridge Crystallographic Data Centre under CCDC 1448987–1448996.

Acknowledgements

We thank the Royal Society (A. B. C.), EPSRC (R. P.) and University of Warwick for financial support. Crystallographic and high-resolution mass-spectrometry data were collected using instruments purchased through support from Advantage West Midlands and the European Regional Development Fund.
