Synthetic access to previously elusive single enantiomers of an octahedral chiral-at-metal rhodium(III) complex containing two cyclometalated 2-phenylbenzothiazoles and two acetonitrile ligands is reported. The complex is a superior chiral Lewis acid catalyst compared to its benzoxazole congener which can be rationalized with a higher steric congestion around the coordination sites.

Chiral Lewis acids play an important role in asymmetric catalysis because many reactions are amenable to Lewis acid activation.¹ Recently, we introduced a new class of chiral Lewis acids based on octahedral iridium(III)^{2–7} and rhodium(III)^{8–11} complexes which draw their chirality exclusively from the metal-centered chirality (metal centrochirality).^{12,13} These chiral-only-at-metal complexes are cyclometalated by two 5-*tert*-butyl-2-phenylbenzoxazoles or the analogous benzothiazole ligands in addition to two exchange-labile acetonitriles, which generates a *C*₂-symmetric, propeller-type geometry.

Whereas the iridium complexes $\Lambda/\Delta\text{-IrO}$ and $\Lambda/\Delta\text{-IrS}$ have been demonstrated to be excellent catalysts for visible light induced photoredox reactions,^{3,4,6,7} the rhodium congener $\Lambda/\Delta\text{-RhO}$ features advantages for regular Lewis acid catalysis,^{8–10} apparently due to a more rapid ligand exchange kinetics (Table 1). We expected that the related complex $\Lambda/\Delta\text{-RhS}$, in which the coordinating benzoxazole moieties are replaced by benzothiazoles, should provide a higher asymmetric induction due to an increased bond length of C–S over C–O which will position the two *tert*-butyl groups somewhat closer to the substrate coordination site. Here we disclose the previously elusive access to the enantiomerically pure benzothiazole complexes Λ - and $\Delta\text{-RhS}$, characterize their structures and configurational

Expanding the family of bis-cyclometalated chiral-at-metal rhodium(III) catalysts with a benzothiazole derivative†

^a Synthesis by an auxiliary-mediated strategy.

stability, and demonstrate their excellent performance as asymmetric catalysts.

The auxiliary-mediated synthesis^{14–18} starts with rhodium trichloride hydrate which is first converted into *rac*-**RhS** in a yield of 73% by reaction with 2 equiv. of 5-*tert*-butyl-2-phenylbenzothiazole (**1**), followed by a treatment with 1.2 equiv. of AgPF₆ in MeCN (Fig. 1). The complex *rac*-**RhS** is then reacted with the monofluorinated salicyloxazoline (*S*)-**2**¹⁹ to provide a diastereomeric mixture of Λ -(*S*)-**3** and Δ -(*S*)-**3** which can be resolved into pure diastereomers (46% each) based on their different solubilities in EtOH or by silica gel chromatography, or a combination thereof depending on the reaction scale. Configurations were assigned based on the crystal structure of Λ -(*S*)-**3** as shown in Fig. 2. Finally, starting with Λ -(*S*)-**3** and Δ -(*S*)-**3**, an acid induced replacement of the coordinated auxiliary ligand with two acetonitriles under retention of the configuration affords the individual enantiomers $\Lambda\text{-RhS}$ (85%) and $\Delta\text{-RhS}$ (80%). The key aspect of this auxiliary-mediated synthesis is the fluorinated auxiliary (*S*)-**2** which was first

introduced by Ceroni and co-workers.¹⁹ All other tested auxiliaries did not provide intermediate rhodium auxiliary complexes with distinct solubilities and were not stable enough for a resolution *via* silica gel chromatography.

The CD spectra of the complexes Λ - and Δ -**RhS** are shown in Fig. 3, and confirm their mirror-imaged structures. HPLC performed on a chiral stationary phase validates the high enantiomeric purity of the individual enantiomers (Fig. 4).²⁰ For the Δ -enantiomer an er of 99.9 : 0.1 was determined, while peak tailing prevents an accurate validation of the Λ -enantiomer and an er of >99 : 1 was estimated.

Fig. 5 shows the superimposed crystal structures of Λ -**RhS** and mirror-imaged Δ -**RhO**, not only confirming the assigned metal-centered configuration of Λ -**RhS**, but also revealing the differences in how the two *tert*-butyl groups flank the coordination site around the two exchange-labile acetonitrile ligands. In comparison with **RhO**, the *tert*-butyl groups of **RhS** are in closer proximity to the labile acetonitriles as quantified by a 0.9 Å shorter intramolecular distance between the quaternary carbons of the two *tert*-butyl groups in **RhS** (10.5 Å) over **RhO** (11.4 Å). This is consistent and analogous with a comparison of the related benzoxazole and benzothiazole iridium complexes.^{3,5}

The increased steric hindrance provided by the two *tert*-butyl groups should make **RhS** an improved asymmetric catalyst for many applications. This is confirmed by the preliminary results shown in Fig. 6. In both enantioselective Michael addition⁸ and a photoinduced enantioselective radical reaction,¹¹ the determined enantioselectivities are appreciably

higher for the benzothiazole (**RhS**) over the benzoxazole (**RhO**) catalyst.²¹

In conclusion, here we reported a new chiral-at-metal benzothiazole complex Λ/Δ -**RhS** which expands the family of bis-cyclometalated rhodium(III) complexes for applications in asymmetric catalysis. Compared to the previously reported benzoxazole complex Λ/Δ -**RhO**, the benzothiazole ligands in Λ/Δ -**RhS** provide a higher steric congestion around the labile acetonitrile ligands, thereby making Λ/Δ -**RhS** a superior asymmetric catalyst. Applications of the new chiral Lewis acid catalyst to challenging asymmetric transformations are underway in our laboratory.

We thank the German Research Foundation (DFG) for financial support of this research (ME 1805/13-1).
