Aluminium salabza complexes for fixation of CO₂
to organic carbonates†

L. Cuesta-Aluja,* J. Castilla and A. M. Masdeu-Bultó*

A highly stable and easy to synthesize aluminium complex bearing a flexible N,N'-donor salabza ligand (N,N'-bis(salicylene)-2-aminobenzylamine) in combination with tetrabutylammonium bromide forms an active binary catalytic system for the cycloaddition of CO₂ to epoxides (TOFs 120–3434 h⁻¹) under mild conditions (10 bar, 80 °C) and low catalyst loadings (0.05–0.2 mol%). Kinetic experiments have shown that the cycloaddition of CO₂ to styrene oxide catalyzed by 1/TBAB is first order in 1, TBAB, CO₂ and epoxide. A reaction mechanism is proposed based on these observations. Fe(III) and Co(III) related complexes are less active catalysts for this reaction.

Introduction

The metal-catalysed coupling of CO₂ and epoxides has become one of the most studied topics in CO₂ activation, as it is an atom-economic reaction to selectively obtain highly value-added cyclic carbonates or polycarbonates from inexpensive and readily available starting materials (Scheme 1). Cyclic carbonates are valuable synthetic targets that are widely used as raw materials for the synthesis of small molecules and polymers. They are also used as electrolytes in lithium-ion secondary batteries and have applications in the chemical industry as excellent polar aprotic solvents. Polycarbonates are high performance, heat and shatter resistant, good electrical insulation, strength, lightness and biodegradability with application in many areas of industry. The increasing demand of these compounds implies the development of new, commercially viable, catalysts and processes which operate under mild reaction conditions.

Catalysts for the coupling of CO₂ and epoxides include halide, quaternary alkyl ammonium or phosphonium salts, as well as ionic liquids and metal complexes. Halide, quaternary salts and ionic liquids are known to produce the most stable thermodynamic product, the cyclic carbonate. This can be explained by the fact that in the absence of a Lewis acid the reaction requires higher temperatures. On the other hand, metal complexes can catalyse the formation of polymer and/or cyclic carbonate products depending on the co-catalyst, substrate and reaction conditions used. In this context, N-heterocyclic amines, phosphines or anions derived from PPN⁺ (PPN⁺ = [Ph₃P=N=N=PPh₃]) and ammonium salts, which act as nucleophiles, have been employed as co-catalysts. In most cases, such binary catalytic systems, Lewis acid/nucleophile, lead to an enhanced activity under milder reaction conditions.

Recently, there has been an increased interest in developing new catalytic systems based on earth-abundant and widely distributed metals such as aluminium and iron. Early studies by Inoue and co-workers showed the possibility of CO₂ activation using Al(III) porphyrin complexes in the presence of imidazole, quaternary ammonium or phosphonium salts. At room temperature and atmospheric pressure of CO₂ tetrphenylporphyrinatoaluminium(III) methoxy derivative [(TPP)AlOMe] in the presence of 1-methylimidazole catalysed the formation of propylene carbonate from CO₂ and propylene oxide. The formation of polycarbonates from CO₂ and epoxides was also achieved using [(TPP)AlCl]/R₄NB or R₄PBr under CO₂ pressure.

A recent outstanding example of highly active catalysts under mild reaction conditions is the hexachlorinated aluminium(III)-aminetriphenolate A (Chart 1) combined with
tetrabutylammonium iodide. This catalytic system gave an initial TOF of 24 000 h\(^{-1}\) in the cycloaddition of CO\(_2\) to 1,2-epoxyhexane at 90 °C and 10 bar of initial CO\(_2\) pressure at very low catalyst loading. However, the molar ratio of catalyst : co-catalyst was high (100).\(^21\)

Some of the most widely employed catalysts in the literature for these reactions are metal–salen type complexes (salen = \(N,N'\)-ethylenbis(salicylimine)) mainly as a result of the pioneering work of Darensbourg with chromium(salen) based catalysts.\(^22\) These catalysts are easily prepared, with the possibility of performing large-scale synthesis. Moreover, they are highly stable and robust. Their reactivity properties can be easily fine-tuned by changing the dimine skeleton or the substituents in the phenolate moiety. Dimeric Al(III) salen complex [Al(salen)\(_2\)](\(\mu\)-O)] (B, Chart 1) reported by Meléndez et al.\(^23\) under solvent-free conditions and using tetrabutylammonium bromide (TBAB) as a co-catalyst displayed a unique activity under atmospheric pressure of CO\(_2\) and at 25 °C.\(^24\) Mononuclear analogous Al(III) salen based catalytic systems require higher pressure and temperature. Thus, Lu et al. have reported an Al(salen)Cl/TBAB catalytic system for the synthesis of ethylene carbonate, which resulted in a rapid formation of the carbonate under supercritical carbon dioxide conditions,\(^25\) however, the rate of conversion was reduced to half when the reaction was carried out at less than 40 bar pressure. Bifunctional aluminum(salen) complexes with appended pyridinium salt substituents,\(^26\) imidazolium-based ionic liquid moiety\(^27\) or \(N\)-methyloxopiperazine moieties\(^28\) in the substituents of the phenolate moieties were efficient catalysts for propylene carbonate formation (TOF up to 297 h\(^{-1}\)). However, the introduction of a second functionality in the skeleton of the catalyst required additional synthesis steps.

Aluminum(salen) complexes together with a series of anionic and neutral co-catalysts were active for the copolymerization of CO\(_2\) and CHO. Darensbourg and co-workers showed that a more electron-withdrawing salen framework was necessary to produce significant quantities of copolymers with a high CO\(_2\) content in the absence of a cyclic carbonate by-product. Nevertheless, the TOFs obtained, ranged from 5.2 to 35.4 h\(^{-1}\), while chromium(salen) systems under similar conditions provided TOFs as high as 1150 h\(^{-1}\).\(^29\)

To sum up, aluminum complexes are indeed efficient for the activation of CO\(_2\), however, they provide low activities and selectivity towards the desired product. Taking this into account we were interested in \(N,N'\)-bis(salicylene)-2-aminobenzylamine(salabza) derivatives as ligands for metal complexes. These complexes would have a more flexible structure than salen derivatives and an open active site, which may provide higher reactivity maintaining the high stability of the tetradentate coordination (Scheme 2). For this reason, we decided to prepare Al(III) complexes with the tetradentate-N\(_2\)O\(_2\) ligand \(N,N'\)-bis(3,5-di-\(t\)-butylsalicylaldehyde)-2-aminobenzylamine derivative (H\(_3\)L, Scheme 2), which is easily synthesised in one step.\(^30\) Iron(III), chromium(III) and cobalt(III) complexes were also prepared. The activity of these metal-salabza complexes in the coupling of CO\(_2\) and epoxides is presented. The synthesis of other Cu, Ti, Mn, Co, Zn and Al complexes with similar salaza-type ligands have already been reported.\(^31\)–\(^34\) A Co(III) complex with a \(2,2\)-dimethylpropyldiamine related skeleton was reported to produce low conversion in the copolymerisation of CO\(_2\) with cyclohexene oxide.\(^35\)

### Results and discussion

#### Syntheses of complexes

Ligand H\(_3\)L was prepared following the general procedure described by Lin and co-workers by the reaction of 3,5-di-\(t\)-butyl salicylaldehyde and 2-aminobenzylamine in ethanol.\(^30\) Treatment of H\(_3\)L with different metal halide precursors MCl\(_3\) (M = Al(III), Fe(III)) afforded the corresponding metal(III) complexes 1 and 2 in good to moderate yield (Scheme 2). Cr(III) and Co(III) complexes were prepared in moderate yields from M(III) salts (CrCl\(_3\) and Co(OAc)\(_2\)·H\(_2\)O) by addition of H\(_3\)L and subsequent oxidation with air (Scheme 2). Compounds 1–4 were isolated as stable solids except in the case of 4, which decomposed under air at room temperature. They were characterized by mass spectrometry, elemental analysis, \(^1\)H and \(^13\)C NMR, IR, UV-visible spectroscopy, magnetic susceptibility (2–4) and X-ray diffraction analysis (2–4).

According to mass spectra (1–4) and X-ray diffraction data (2–4), they all formed mononuclear species and no evidence...
of bimetallic species was found. Probably, the tert-butyl substituents together with the more hindered six membered diamine ring prevented the formation of dinuclear species.

The molecular structures of 2–4 were obtained by single-crystal X-ray diffraction analysis (Fig. 1–3). Purple crystals of 2 were obtained by slow evaporation of a diluted solution of the complex in diethyl ether/hexane. 2 presented a 5-coordinated environment (Fig. 1) with the geometry around the iron center intermediate between trigonal bipyramidal and square-pyramidal.36 This geometry differed from those reported for [Fe(salen)]Cl–C6H6,37 [Fe(salphen)Cl],38 and other iron salen-type complexes,39 which had a perfect square-pyramidal geometry. The length of the diimine ligand could be considered to influence the iron environment producing this change in

![Fig. 2 ORTEP drawing of complex 3. All hydrogen atoms and solvent molecules are omitted for clarity. Thermal ellipsoids are drawn at the 50% probability level. Selected bond lengths (Å) and angles (°): Co1a–O1a 1.8668(16), Co1a–O(4a) 1.867(6), Co1a–N1a 1.8947(7), Co1a–N2a 1.8986(5), Co1a–O1a–O(4a) 1.975(5), Co1a–O(4a)–O(3) 2.053(5), O1a–Co1a–O3 166.5(4), O4a–Co1a–N2a 94.2(3), N2a–Co1a–N1a 90.8(5), O1a–Co1a–O21 101.7(3), O21–Co1a–O(4a) 85.9(3) and O2–Co1a–O(3) 64.8(18).](image2)

the geometry. The Fe–N(imine) (2.139(2) and 2.0858(19) Å), Fe–O(phenolate) (1.8659(16) and 1.8995(16) Å) and Fe(II) bond distances are in agreement with the reported data from other salen-type iron complexes.37,38 The Fe–N(imine) distance has been suggested as an indicator of the spin state for Fe(II) in salen iron complexes, with a distance of 2.00–2.10 Å for the high-spin state, and 1.93–1.96 Å for the low-spin state.40 The mean bond distance in the structure described here suggests that the metal ion in 2 is in the high-spin state, which is consistent with the results of room temperature magnetic susceptibility ($\mu_{\text{eff}} = 5.90 \mu_B$).40

Brown crystals of 3 were obtained by slow evaporation of a diluted solution of the complex in diethyl ether/hexane. As shown in Fig. 2 the molecular structure of 3 was also monomeric with a six-coordinated central cobalt atom. In this case L2– acted also as a tetradeutated anionic ligand and one acetate ion as a bidentate chelate. Evidence of the chelate acetate was also obtained from IR spectra1,42 by the presence of one strong band at 1525 cm$^{-1}$ and another presumably in the overcrowded $\nu(C=C)$ range of 1478–1490 cm$^{-1}$ ($\nu(CO)$ and $\nu(COO)$ respectively) with a $\Delta v$ value between 116–47 cm$^{-1}$.42 The geometry around the cobalt atom (Fig. 2) was a distorted octahedral similar to analogous Co(III) salen complexes in the literature.15,43 Bond distances Co–N (imino), Co–O (phenolate) and Co–O (acetate) (Fig. 2) are in the average range as the corresponding values in similar octahedral Co(III) systems.43

Complex 4 adopted also an octahedral geometry around the chromium metal centre where the anionic ligand L2– was coordinated in the equatorial plane in a tetradeutated fashion through the imine and phenolate O atoms (Fig. 3). One chloride anion and a water molecule, coming from wet air in the oxidation step, were located at the axial positions. The equatorial donor atoms presented a nearly planar geometry (Fig. 3). The chloride anion and the water molecule were located with an almost linear disposition (O(3)–Cr(1)–Cl(1) bond angle of 177.13(18)$^\circ$). The Cr–N (imine), Cr–O (phenolate) as well as Cr–Cl bond lengths observed were in concordance with the
Cycloadition of CO$_2$ to monosubstituted epoxides

Initially, complexes 1–4 were tested as catalysts, in conjunction with TBAB, for the coupling reaction of CO$_2$ and 1,2-epoxyhexane as a benchmark substrate. The complexes were soluble in the net substrate; therefore no additional solvent was required. The initial reaction conditions were 10 bar CO$_2$, 45 °C using 0.2 mol% complex and 0.2 mol% TBAB over 18 h. Catalysts 2–4/TBAB catalysed the coupling of CO$_2$ and 1,2-epoxyhexane to produce the cyclic carbonate selectively (Table 1). In the case of catalyst 4/TBAB we obtained nonreproducible results probably due to decomposition. Under these conditions, the best result was achieved with the 1/TBAB catalytic system with almost 50% of conversion and total selectivity towards cyclic carbonate (entries 1–3, Table 1). The higher Lewis acidity of the Al(III) centre compared to Fe(III) and Co(III) may explain the higher conversion obtained with 1/TBAB although other factors related with the stability of the intermediates should also be taken into account. With this catalytic system, an increase of the catalyst/co-catalyst ratio to 1/5 (1.0 mol% co-catalyst loading) produced an enhancement in the catalytic activity up to 100% conversion (entry 4, Table 1). However, in the absence of a co-catalyst almost no cyclic carbonate was formed even when running the reaction at 80 °C (entry 5, Table 1). It is important to note that TBAB alone showed very low conversion under the employed catalytic conditions (entry 6, Table 1). This synergistic effect between the aluminium complex 1 and TBAB is in concordance with the analogous behaviour observed with other catalytic systems for the same reaction.\textsuperscript{21,46}

The effect of pressure (10, 30 and 50 bar) and temperature (45, 60, 80 °C) was also evaluated at 18 h of reaction time with 1/TBAB (catalyst/co-catalyst = 1) (Fig. 4). As expected the temperature has a beneficial effect in the conversion even when the CO$_2$ pressure increases up to 50 bar. On the other hand, raising the pressure produced an increase of conversion when working at 45 and 60 °C. When the reaction was run at 80 °C, no positive effect was observed by increasing the pressure from 10 to 50 bar.

At the optimized temperature (80 °C), pressure (10 bar) and catalyst/co-catalyst ratio of 5 we proceeded to optimize the catalytic system at a catalyst loading of 0.05/0.25 mol% at 90 °C and 10 bar CO$_2$ initial pressure (TOF 900 h$^{-1}$).\textsuperscript{21} However, it is higher than the one obtained with the dimeric aluminium complex 1, entry 1, Table 2).

To assess if the catalytic activity was maintained under milder reaction conditions the same reaction was performed at 45 °C (entry 2, Table 2) and under an atmospheric pressure of CO$_2$ (entry 3, Table 2). In both cases a decrease in the catalytic activity was observed (TOF 90 and 267 h$^{-1}$ respectively), but the initial TOF at atmospheric pressure was still encouraging. A maximum TOF of 800 h$^{-1}$ was obtained at a catalyst loading of 0.05 mol% in 0.5 h of reaction time (entry 4, Table 2). This value is slightly lower than the one reported using the hexa-chloro Al(III)(amine triphenolate)/TBAI catalytic system at a similar catalyst/co-catalyst ratio (0.05/0.25 mol%) at 90 °C and 10 bar CO$_2$ initial pressure (TOF 990 h$^{-1}$).\textsuperscript{21} Measurements were run in duplicate.

The catalytic activity of 1/TBAB was studied in the cycloaddition of CO$_2$ to a variety of terminal and functionalized epoxides providing the corresponding cyclic carbonates (Fig. 5). All of these selected substrates were converted into the corresponding carbonates with total selectivity in the cyclic product at a turn over frequency between 120 and 3434 h$^{-1}$ (Fig. 5). This information indicated the high tolerance of the catalytic system especially with alkyl halide functionalities such as 1-chloro-2,3-epoxypropane, which presented the highest catalytic activity. It is remarkable that the catalyst 1/TBAB was active for internal hindered substrates, such as methyl epoxyoleate derived from a natural product, than the ones reported for Al(III) Schiff base ligands with a similar propyl diamine skeleton when NEt$_3$OAc was used as a co-catalyst.

### Polycondensation of CO$_2$ with cyclohexene oxide

The reaction of CO$_2$ and cyclohexene oxide (CHO) was then investigated using catalyst 1 and changing the co-catalyst to a most effective Lewis base co-catalyst for this reaction such as (bis(triphenylphosphine)iminium chloride (PPNCl)). The copolymerization reaction was carried out initially at 80 °C and 50 bar over 18 h with 1 complex (0.2 mol%) in the presence of an equimolar amount of PPNCl without the addition of solvent (entry 1, Table 3). The $^1$H NMR of the crude of the reaction showed a peak at δ 4.6 ppm characteristic of poly(cyclohexene carbonate) (PCHC) together with signals at δ 4.5 and δ 4.0 ppm attributed to the cis- and trans-cyclohexene carbonate (CHC) respectively (ratio cis/trans 75/25, ratio PCHC/CHC 71/29). The formation of mixtures of polycarbonate and cyclic carbonate in the reaction of CHO and CO$_2$ is consistent with the fact that the actvation energy for the formation of PCHC is lower compared to other substrates; nevertheless, the cyclic product is still the most stable thermodynamically. Indeed, Darenbourg and co-workers observed almost total selectivity towards the cyclic carbonate by-product using PPNCl with similar aluminum–salen complexes. The polymer was isolated by extraction of the cyclic product with hexane obtaining a polycarbonate with a high degree of incorporation of CO$_2$ (92%) measured by $^1$H NMR spectroscopy. The number-average molecular weight ($M_a$) of the alternating copolymer and polydispersity ($M_w/M_n$), estimated by gel permeation chromatography (GPC), was 1700 and 1.3, respectively (entry 1, Table 3). Polycarbonate oligomers with diol functionalities are interesting materials for the synthesis of polyurethanes.

The selectivity towards the polycarbonate increased up to 84% by decreasing the temperature reaction to 25 °C at longer reaction time (entries 2 and 3, Table 3). At this temperature the $M_n$ of the poly(cyclohexene carbonate) increased up to 2900. Similarly, when the CO$_2$ pressure decreased to 10 bar at 45 °C the reaction proceeded at 63% conversion although the % CO$_2$ incorporation decreased to 85% and the cyclic carbonate increased due to decrease of the CO$_2$ insertion (entry 4, Table 3). The conversions obtained with 1/PPNCl were higher than the ones reported for Al(III) Schiff base ligands with a similar propyl diamine skeleton when NEt$_3$OAc was used as a co-catalyst.
catalyst.\textsuperscript{52} Instead, the polymers obtained by the 1/PPNCl catalytic system possessed a lower molecular weight than the one reported by Inoue and coworkers with salophen aluminium Schiff base complexes. Still, the polydispersity obtained was higher (2.47, 20 bar, 80 °C) compared with the 1/PPNCl catalytic system (1.3, 10 bar, 45 °C). It is also remarkable for the use of solvent-free conditions.

Analyses of the polycarbonates by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF) revealed two distributions in the polycarbonates formed (Fig. 6). The major distribution was attributed to a chain with the presence of −Cl as well as −OH as end groups (a + K in Fig. 6) and the second distribution fitted with chains with two −OH terminal groups (b + K in Fig. 6). This observation suggests that chain a (Fig. 6) was formed by an initiation step involving the opening of the epoxide by a nucleophilic attack of the chloride anion, which, presumably, comes from the PPNCl co-catalyst, to the coordinated epoxide. On the other hand, chain b (Fig. 6), which contains two terminal −OH, suggests that the initiation step involves the opening of the epoxide by a nucleophilic attack with −OH originating from traces of water present in the reactor. The termination step for both polymer chains may proceed by hydrolysis.

Mechanistic studies for the cycloaddition of CO\textsubscript{2} to styrene oxide

In order to elucidate the mechanism of the cycloaddition of CO\textsubscript{2} to styrene oxide \textsuperscript{27}Al NMR spectra and kinetic studies were undertaken. \textsuperscript{27}Al NMR spectrum in CDCl\textsubscript{3} of 1 exhibited a single broad and strong resonance centred at δ 50 ppm with a width of 65−35 ppm (a, Fig. 7), which probably collapses with the probe background\textsuperscript{53} and can be attributed to a pentacoordinate species.\textsuperscript{54−56} When an equimolar amount of styrene oxide was added into the NMR tube containing 1 two defined signals appeared at δ 40.01 ppm and δ 3.70 ppm (b, Fig. 7). According to the literature data we assigned the downfield broad signal to the pentacoordinate complex 1, whereas the upfield signal could be ascribed to a hexacoordinated complex: this compound was formed by the coordination of styrene oxide to the aluminium metal center.\textsuperscript{57−59} At this point it was proposed that in an initial step an equilibrium between the pentacoordinated 1 and hexacoordinated 1-SO takes place (Scheme 3). To continue with the investigation of the role of the aluminium complex, the co-catalyst and the CO\textsubscript{2} pressure in the reaction mechanism, a kinetic study of the formation of cyclic styrene carbonate catalyzed by the 1/TBAB system was undertaken. Solvent-free conditions were chosen using a neat substrate to work in a similar environment to that in the catalytic studies. The reaction kinetics was monitored by sampling and subsequent analyses by \textsuperscript{1}H NMR spectroscopy to determine the conversion of epoxide to cyclic carbonate. The approximations taken into consideration were those reported in the literature for similar studies.\textsuperscript{60−63} It was assumed that the concentration of 1 and TBAB does not change during the reaction since they both act as catalysts, and CO\textsubscript{2} is present in large excess due to the semi-batch operation. Thus, the general rate law (eqn (1)) can be transformed in eqn (2).

\[
\text{rate} = k_{\text{obs}}[\text{CO}_2]^b[1]^c[\text{TBAB}]^d
\]  
\[
\text{rate} = k_{\text{obs}}[\text{SO}]^g
\]  

where \(k_{\text{obs}} = [\text{CO}_2]^b[1]^c[\text{TBAB}]^d\).

![Fig. 6 MALDI-TOF mass spectrum of polycarbonate from entry 4, Table 3.](image-url)

![Scheme 3 Equilibrium between five and six-coordinated aluminium species.](image-url)
The representation of styrene oxide (SO) in front of time suggested a pseudo-first order dependence with respect to the substrate since there is a linear dependence of ln[SO] as a function of time (a = 1, eqn (2)) [Fig. S28†]. Contrary to the observations by North and co-workers using catalyst B/TBAB (Chart 1) in the synthesis of styrene carbonate, no induction period was detected using the catalytic system 1/TBAB. The same authors showed that the reaction under solvent-free conditions was pseudo-zero order whereas in solvent it was first order with respect to the starting material.65

To determine the order with respect to the catalyst 1 and the co-catalyst TBAB, the reactions were performed maintaining constant the reaction temperature and working in the presence of an excess of CO2. Under these conditions its concentration may be considered pseudo constant at the initial stage of the reaction. Thus, the natural logarithm of the rate law (kobs = k[CO2]1[B]1[TBAB]d) results in ln kobs = ln k + b ln[CO2] + c ln[1] + d ln[TBAB], from which it is possible to afford the orders b−d with respect to the catalyst, co-catalyst and CO2 concentration by examination of the double logarithmic plot for each case. Thus, initially, the pressure of CO2 and the amount of TBAB was fixed at 0.2 mol% while the concentration of 1 was varied between 0.1 and 0.4 mol%. Similarly, the pressure of CO2 and the concentration of 1 were maintained at 0.2 mol% and TBAB concentration was changed from 0.2–1.0 mol%. The double logarithmic plot of the initial rates against the catalyst or the co-catalyst concentration (see Fig. S29–S34 in ES†) shows a linear dependence with a slope of 0.6618 and 1.1127, respectively, suggesting that the reaction was first order with respect to the catalyst and co-catalyst and CO2 concentration by examination of the double logarithmic plot for each case. Thus, initially, the pressure of CO2 and the amount of TBAB was fixed at 0.2 mol% while the concentration of 1 was varied between 0.1 and 0.4 mol%. Similarly, the pressure of CO2 and the concentration of 1 were maintained at 0.2 mol% and TBAB concentration was changed from 0.2–1.0 mol%.

The double logarithmic plot of the initial rates against the catalyst or the co-catalyst concentration (see Fig. S29–S34 in ES†) shows a linear dependence with a slope of 0.6618 and 1.1127, respectively, suggesting that the reaction was first order with respect to the catalyst and co-catalyst and CO2 concentration by examination of the double logarithmic plot for each case. Thus, initially, the pressure of CO2 and the amount of TBAB was fixed at 0.2 mol% while the concentration of 1 was varied between 0.1 and 0.4 mol%. Similarly, the pressure of CO2 and the concentration of 1 were maintained at 0.2 mol% and TBAB concentration was changed from 0.2–1.0 mol%. The double logarithmic plot of the initial rates against the catalyst or the co-catalyst concentration (see Fig. S29–S34 in ES†) shows a linear dependence with a slope of 0.6618 and 1.1127, respectively, suggesting that the reaction was first order with respect to the catalyst and co-catalyst and CO2 concentration by examination of the double logarithmic plot for each case. Thus, initially, the pressure of CO2 and the amount of TBAB was fixed at 0.2 mol% while the concentration of 1 was varied between 0.1 and 0.4 mol%. Similarly, the pressure of CO2 and the concentration of 1 were maintained at 0.2 mol% and TBAB concentration was changed from 0.2–1.0 mol%.

The double logarithmic plot of the initial rates against the catalyst or the co-catalyst concentration (see Fig. S29–S34 in ES†) shows a linear dependence with a slope of 0.6618 and 1.1127, respectively, suggesting that the reaction was first order with respect to the catalyst and co-catalyst and CO2 concentration by examination of the double logarithmic plot for each case. Thus, initially, the pressure of CO2 and the amount of TBAB was fixed at 0.2 mol% while the concentration of 1 was varied between 0.1 and 0.4 mol%. Similarly, the pressure of CO2 and the concentration of 1 were maintained at 0.2 mol% and TBAB concentration was changed from 0.2–1.0 mol%.

to react easily with CO₂ forming a carbonate Al(III) species. This intermediate can either form a polycarbonate through further alternating insertions of epoxide and CO₂ or a cyclic carbonate monomer via intramolecular rearrangement and leaving group liberation.

Conclusion

In this work we reported new catalytic systems based on tetra-dentate N₂O₂ salabza metal catalysts. In particular, aluminium complex 1, was found to be very stable and easy to synthesize from a simple aluminium trichloride salt. This mononuclear aluminium complex, combined with TBAB, formed an active binary catalytic system for cycloaddition of CO₂ and epoxides. This catalytic system provides cyclic carbonates selectively with excellent conversions even at low pressures of CO₂ (up to 94% at 10 bar). Higher catalytic activities were obtained with functionalized terminal epoxides such 1-chloro-2,3-epoxypropane at 10 bar).}

**Experimental**

**Synthesis of [N,N'-bis(3,5-di-tert-butyllsalicylenc)-2-aminobenzyl-amino]chloridoaluminium(III) (1)**

Anhydrous AlCl₃ (144.1 mg, 1.08 mmol) was added to a solution of H₂L (400 mg, 0.72 mmol) in 15 mL of dry THF. The yellow solution was stirred for 4 h at room temperature under an inert atmosphere, filtered over Celite and the filtrate was evaporated under vacuum. The resulting solid was washed with acetonitrile, pentane and dried again. Bright yellow solid, 377.4 mg, (yield 85%).

**NMR (400 MHz, CDCl₃, ppm):**

- δ 1.28 (s, 9H, tBu), 1.33 (s, 9H, tBu), 1.52 (s, 9H, tBu), 1.57 (s, 9H, tBu), 4.80 (br, 2H, ArCH₂N), 7.04 (d, 1H, CH-phenol, J = 2.4 Hz), 7.20 (d, 1H, CH-phenol, J = 2.4 Hz), 7.22–7.27 (m, 3H, ArH), 7.38 (m, 1H, ArH), 7.54 (d, 1H, CH-phenol, J = 2.4 Hz), 7.66 (d, 1H, CH-phenol, J = 2.4 Hz), 8.35 (s, 1H, CH=CH=CH=CH=N), 8.42 (s, 1H, CH=CH=N), 13C NMR (75.43 MHz, CDCl₃, ppm): δ 29.78, 29.83 (CH₃, tBu), 31.37, 31.40 (CH₃, tBu), 34.09, 34.20 (C, tBu), 35.56, 35.67 (C, tBu), 62.63 (CH₃), 118.08, 119.25, 123.15, 126.78, 127.41, 127.57, 128.51, 130.08, 131.57, 131.68, 132.95, 138.96, 139.55, 140.94, 141.44, 148.28, 162.84, 164.02, 171.63, 171.87.

UV-vis (CH₃CN, 2.5 × 10⁻⁵ M): λ (nm) (ε, L mol⁻¹ cm⁻¹):

- 226.0 (116 100), 282.0 (41 884), 369.0 (18 752).

Analy. calcd for C₁₂₂H₁₅₄Cl₂AlN₂O₂: C, 68.24; H, 8.05; N, 4.30. Found: C, 68.11; H, 8.21; N, 4.03. HRMS (ESI, m/z) calculated for [M − Cl]⁺: 579.3531, found 579.3503.

**Synthesis of [N,N'-bis(3,5-di-tert-butyllsalicylenc)-2-aminobenzyl-amino]chloridochromium(III) (3)**

A 10 mL MeOH solution of FeCl₃ (90.5 mg, 0.56 mmol) was added dropwise to a 10 mL CH₂CN suspension containing H₂L (309.4 mg, 0.56 mmol) and Et₃N (0.15 mL, 1.12 mmol). The resulting solution changed color to dark purple and was gently refluxed for 2 h. Then the solution was filtered while warm and concentrated to one-third of the original volume. The filtrate was dissolved with CH₃Cl₂, filtered again over Celite and the volatiles removed. The solid was further washed with hexane and dried under vacuum. Black solid, 302 mg, (yield 85%).

UV-vis (CH₃CN, 2.5 × 10⁻⁵ M): λ (nm) (ε, L mol⁻¹ cm⁻¹):

- 220.0 (86 576), 240.0 (31 304), 276.0 (23 496), 332.0 (11 528), 532.0 (3948).

μₑffective (25 °C) = 5.90μ₀. Analy. calcd for C₆₇H₇₄ClFeN₂O₂: C, 69.00; H, 7.51; N, 4.35. Found: C, 69.29; H, 7.99; N, 4.40. HRMS (ESI, THF, m/z) calculated for [M − Cl]⁺: 608.3065, found: 608.3038.

**Synthesis of [acacetato-k²-O,O]N,N'-bis(3,5-di-tert-butyllsalicylenc)-2-aminobenzyl-amino]chloridocobalt(III) (2)**

To a stirred solution of H₂L (300 mg, 0.54 mmol) in THF (10 mL) at room temperature under an inert atmosphere, an ethanol solution (10 mL) containing 1.0 equiv. of Co(OAc)₂·2H₂O (134.7 mg, 0.54 mmol) was added. The reaction mixture was refluxed for 1 h under an inert atmosphere, cooled down to room temperature and was further stirred under an air stream for 6 h. The resultant solution was concentrated and hexane was added to precipitate the product, which was filtered off, washed with diethyl ether and hexane, and dried under vacuum. Dark red solid, 180.3 mg, (yield: 49%).

**NMR (400 MHz, CDCl₃, ppm):**

- δ 1.16 (br, 9H, tBu), 1.25 (br, 9H, tBu), 1.30 (br, 9H, tBu), 1.45 (br, 9H, tBu), 1.59 (br, 3H, CH₃–OAc), 4.17 (d, 1H, ArCH₂N, J = 13.6 Hz), 4.54 (d, 1H, ArCH₂N, J = 12.4 Hz), 6.99 (br, 1H, ArH), 7.08 (br, 1H, ArH), 7.16 (br, 1H, ArH), 7.34–7.36 (br, 2H, ArH), 7.44 (br, 1H, ArH), 7.75 (br, 1H, CH=CH=N), 7.85 (br, 1H, CH=CH=N). UV-vis (CH₂CN, 2.5 × 10⁻⁵ M): λ (nm) (ε, L mol⁻¹ cm⁻¹):

- 217.0 (78 980), 230.0 (35 624), 258.0 (36 144), 416.0 (6088).

μₑffective (25 °C) = 0.05μ₀. Analy. calcd for C₄₇H₄₈CoN₂O₂·H₂O·CH₃CH₂OH: C, 68.36; H, 8.02; N, 3.99. Found: C, 68.42; H, 7.83; N, 3.79. HRMS (ESI, THF, m/z) calculated for [M – OAc]⁺: 611.3048, found: 611.3060.

**Synthesis of aqua[N,N'-bis(3,5-di-tert-butyllsalicylenc)-2-aminobenzyl-amino]chloridochromium(III) (4)**

To a stirred solution of H₂L (300.0 mg, 0.5407 mmol) in THF (15 mL) anhydrous CrCl₃ (66.5 mg, 0.5407 mmol) was added. The resulting mixture was stirred under nitrogen at room temperature for 3 h. Then, it was further stirred under air for 3 h. This produced a dark orange solution. The orange solution was filtered over Celite and the filtrate was evaporated under vacuum. Dark red solid, 57.7 mg, (yield: 23%).
3 h. The solution was filtered over Celite and the filtrate was evaporated under vacuum. Cold hexane was added to the brown mixture. The suspension was filtered off and the solid was washed with hexane and dried under vacuum. Brown solid, 193.7 mg, (yield 55%). Anal. calcd for C_{37}H_{50}ClCrN_2O_3·H_2O·OC_4H_8: C, 65.80; H, 8.08; N 3.74. Found: C, 65.99; H, 8.02; N, 3.86. HRMS (ESI, THF, m/z) calculated for [M − Cl − H_2O]^+: 604.3121, found: 604.3206.

**X-ray crystallography**

Diffraction data for the structures reported were collected on a Smart CCD 1000 Bruker diffractometer system with Mo Kα radiation (λ = 0.71073 Å). Cell refinement, indexing and scaling of the data sets were carried out using programs Bruker Smart and Bruker Saint. All the structures were solved by SIR97 and refined by SHELXL98 and the molecular graphics with ORTEP-3 for Windows.69 All the calculations were performed using the WinGX publication routines.70 Crystallographic data are collected in Table S1 (ESI†).

**Standard procedure for the synthesis of cyclic carbonates**

The catalytic tests were carried out in a 100 mL Berghof reactor, which was previously kept for 4 hours under vacuum at 100 °C. After cooling, a solution under an inert atmosphere containing the catalyst dissolved in a neat distilled substrate and the co-catalyst, when indicated, was injected into the reactor. The autoclave was pressurized with CO_2, and then heated to the specific temperature to reach the desired pressure. After the reaction time, the reactor was cooled with an ice bath and slowly depressurized (with PO a dichloromethane trap was used). The conversion was determined by ^1H NMR of the crude mixture by the integral ratio between the alkene oxide and cyclic carbonate. The yield was determined by ^1H NMR using mesitylene as the internal standard.

**Standard procedure for copolymerization with cyclohexene oxide**

Using the same procedure for the synthesis of cyclic carbonates the conversion was also determined by ^1H NMR of the crude mixture by the integral ratio between the alkene oxide with the copolymer and cyclic carbonate. The yield was determined by ^1H NMR using mesitylene as the internal standard. The final mixture was dissolved in dichloromethane, the solvent was evaporated and the residue dried under vacuum at 100 °C for 3 hours to remove excess of cyclohexene oxide. The final residue was washed several times with hexane to purify the poly (carbonate) and was analysed by ^1H NMR spectroscopy. The CO_2 content was calculated from ^1H NMR data by the integral ratio between copolymer carbonate linkages (δ = 4.65 ppm) with respect to ether linkage signals (δ = 3.45 ppm).

**Standard kinetic experiment procedure**

A Parr 477 autoclave equipped with a proportional-integral-derivative (PID) temperature controller and gas reservoir was used for kinetic experiments in the reaction of styrene oxide with CO_2. In a typical experiment, the autoclave was charged with the catalyst and co-catalyst in neat distilled styrene oxide, heated and pressurized with CO_2. Samples were taken at the determined time and the conversion of the product was determined by ^1H NMR spectroscopy. After the reaction time the autoclave was depressurized.
