Oxygen activation and catalytic aerobic oxidation by Mo(IV)/(VI) complexes with functionalized iminophenolate ligands
Oxygen activation and catalytic aerobic oxidation by Mo(IV)/(VI) complexes with functionalized iminophenolate ligands†

Niklas Zwettler, Martina E. Judmaier, Lara Strohmeier, Ferdinand Belaj and Nadia C. Mösch-Zanetti*

Synthesis of molybdenum(VI) dioxido complexes 1–3, coordinated by one or two functionalized iminophenolate ligands HL1 or HL2, bearing a donor atom side chain or a phenyl substituent, respectively, allowed for systematic investigation of the oxygen atom transfer (OAT) reactivity of such complexes towards phosphanes. Depending on stoichiometry and employed phosphane (PMe3 or PPh3), different molybdenum(VI) and molybdenum(IV) complexes 4–7 were obtained. Whereas molybdenum(IV) complexes 4 and 5, bearing a terminal PMe3 ligand, readily reacted with molecular O2 to form oxido peroxido complexes 8 and 9, phosphane free µ-oxido bridged dinuclear molybdenum(VI) complexes 6 and 7 proved to be stable towards oxidation with molecular O2 under ambient conditions. Single-crystal X-ray diffraction analyses revealed different isomeric structures in the solid state for dioxido complexes 1 and 2 in comparison with oxido phosphane complex 5, dinuclear oxido µ-oxido complex 6 and oxido peroxido complexes 8 and 9, pointing towards an isomeric rearrangement during OAT. Compounds 1 and 2 were furthermore tested for their ability to catalyze the aerobic oxidation of PMe3 and PPh3. A significant difference in catalytic activity has been observed in the oxidation of PMe3, where complex 1 bearing donor atom functionalized ligands led to higher conversion and selectivity than complex 2 coordinated by phenyl iminophenolate ligands. In the oxidation of PPh3, complex 2 leads to higher conversion compared to 1. In a control experiment, phenyl-based dinuclear µ-oxido complex 7, derived from complex 2, was found to be catalytically active, which suggests a lower energy barrier for disproportionation into [MoO-\(\text{L}_2\)] and [MoO\(_2\)\(\text{L}_2\)] in comparison with methoxypropylene based compound 6, a prerequisite for subsequent reactivity toward molecular O2.

Introduction

The chemistry of molybdenum, as an abundant and biologically relevant transition metal, has been well established over the course of the past few decades. Especially in biomimetic chemistry, much effort has been made to elucidate and mimic the structure and function of various molybdoenzymes. An important class among these enzymes is represented by xanthine oxidase, which contain a molybdenum(VI) metal centre coordinated by an oxido ligand, as well as depending on the enzyme, one or two molybdopterin ligands. These oxo-transferases catalyze oxygen atom transfer reactions via a molybdenum(VI)/molybdenum(IV) redox cycle. Whereas early modelling approaches for the corresponding active sites focused on sulfur rich dithiolene ligands, several other structurally diverse ligand systems have been explored. The ease of such molybdenum compounds to undergo oxygen atom transfer made them also interesting in industrial applications. Especially for the catalytic oxidation of alkenes to epoxides, several highly efficient systems exist nowadays.

In general, these catalysts use H\(_2\)O\(_2\) or organic peroxides such as tert-butyl hydroperoxide (TBHP) as terminal oxidants. In our group, Mo(VI) dioxido systems were investigated for their applicability in oxygen atom transfer (OAT) reactions as well as epoxidation catalysis. In that course, iminophenolate-based complexes incorporating different functionalities were developed. While amides as internal hydrogen bond donors led to unprecedented C-C and C-N coupling behavior upon coordination, the introduction of donor atoms (ether or amine) led to Mo(VI) catalysts for highly selective oxidation of a broad scope of alkene substrates with TBHP.
Nevertheless, one of the major drawbacks of to date reported catalysts is the necessity of a terminal oxidant. To develop more sustainable catalytic processes it is of great interest to allow for the use of molecular oxygen and in further consequence air as a benign alternative to other oxidants. Not only is oxygen abundant, cheap and environmentally harmless, its use also reduces the formation of undesired side products.\textsuperscript{11} Whereas the activation of molecular oxygen has been described and thoroughly investigated for a variety of transition metals (e.g. iron, manganese),\textsuperscript{12} the number of molybdenum complexes that activate molecular oxygen is very limited. Only a few examples with full structural characterization have been disclosed,\textsuperscript{13,14} among them two examples are from our group.\textsuperscript{15,16} In general there are only a few examples of homogeneously catalyzed aerobic oxidation reactions using a Mo catalyst and these are severely hampered by disadvantages such as high catalyst loadings or the need of a co-catalyst.\textsuperscript{17} Since the number of molybdenum oxido peroxido compounds originating from oxygen activation is scarce, it is important to gain further insight into the electronic and structural parameters affecting the applicability of Mo(nV)/Mo(nVI) systems for oxygen atom transfer as well as oxygen activation. Our group has thus an ongoing research interest in the OAT systems for catalytic aerobic oxidation reactions employing these ligands and investigated for their behavior in OAT reactions with the tertiary phosphines PMe\textsubscript{3} and PPh\textsubscript{3} and subsequent reactivity towards molecular oxygen. Structural characterization \textit{via} single-crystal X-ray diffraction analyses allowed assessing the isomeric structures of the participating species. Furthermore, catalytic oxidation of the phosphines by molecular oxygen revealed significant reactivity differences depending on phosphines and catalysts employed. Both investigated systems surpassed the PMe\textsubscript{3} conversion obtained using a previously published system.\textsuperscript{16}

**Results and discussion**

**Ligand synthesis**

Previously published ligands HL\textsubscript{1} \textsuperscript{18} and HL\textsubscript{2} \textsuperscript{19} were prepared using well established synthetic protocols. Briefly, 1.1 equiv. of a primary amine bearing the desired functionality were added to a methanolic solution of 3,5-di-tert-butyl-2-hydroxy-benzaldehyde and stirred overnight at reflux temperature. Whereas HL\textsubscript{1} was obtained after evaporation of the solvent as a yellow oil, HL\textsubscript{2} was recovered as an orange crystalline solid after filtration (Scheme 1). Their analytic data is in agreement with the literature.\textsuperscript{18,19}

**Synthesis of molybdenum dioxido complexes**

For the synthesis of molybdenum(nVI) complexes of the type [MoO\textsubscript{2}(L)\textsubscript{2}], synthetic procedures using [MoO\textsubscript{2}(acac)\textsubscript{2}],\textsuperscript{20} [MoO\textsubscript{2}Cl\textsubscript{2}] and [MoO\textsubscript{2}Cl\textsubscript{2}(DME)]\textsuperscript{21} (DME = dimethoxyethane) as metal sources were investigated. A reaction of two equiv. of HL\textsubscript{1} and HL\textsubscript{2}, respectively, with the metal precursors [MoO\textsubscript{2}Cl\textsubscript{2}(DME)] and [MoO\textsubscript{2}Cl\textsubscript{2}] in the presence of excess NET\textsubscript{3} in toluene, led to the targeted [MoO\textsubscript{2}(L)\textsubscript{2}] complexes 1 and 2 in good yields (Scheme 2).

Generally, there are three possible isomers for molybdenum(nVI) compounds with a \textit{cis} dioxido arrangement coordinated by two iminophenolate ligands as depicted in Fig. 1. For complexes 1 and 2, \textit{H} NMR data in C\textsubscript{6}D\textsubscript{6} are consistent with the existence of two isomers in solution. One set of ligand resonances corresponds to isomer A as confirmed by single-crystal X-ray diffraction analysis. In principle also the O,O isomer B would feature one set of resonances but this would require a rotation of both ligands upon crystallization which seems highly unlikely. The non-equivalent ligand arrangement of the second isomer C in solution gives rise to two additional sets of ligand resonances. The ratio of the two isomeric forms is strongly dependent on...
the imine substituent. Whereas in the compound bearing the methoxypropylene-substituted ligands, the N,N form is predomi-
nant with a ratio of 3 : 1, in the complex with the phenyl-sub-
stituted ligand, the major isomer corresponds to the O,N form
with a ratio of 2 : 3 (Scheme 2). In compound 1, the signals for
the minor isomer are considerably broadened, as previously
observed,7 whereas no significant broadening is observed in the
1H NMR spectrum of 2 at room temperature.

Dissolution of single crystals of 2 and immediate recording of
1H NMR spectra led to the same isomeric ratio in several
attempts, suggesting a dynamic equilibrium in solution. Sub-
sequent variable temperature 1H NMR spectroscopy of
complex 2 in C6D6 (Fig. S6†) showed a significant broadening
of the O,N isomeric resonances upon heating accompanied by
a slight change in the isomeric ratio [N,N : O,N approx. 2 : 3 at
9 °C to 5 : 6 at 50 °C]. Similarly results have been reported pre-
viously for a complex closely related to 1 (R = methoxymethyl-
ene).7 A more pronounced effect can be observed in the 1H
NMR spectra of single crystals of 2 in different solvents
(CD3CN, CD2Cl2, Fig. S7†), where the isomeric N,N : O,N ratios
are 1 : 1.2 (CD2Cl2) and 1.7 : 1 (CD3CN), respectively, as recently
observed for Re(V) iminophenolate complexes,22 further corro-
bating a dynamic equilibrium in solution.

Upon using [MoO2(acac)2] as a precursor, compound 1 was
obtained in significant lower yield and compound 2 did not
form. However, the monosubstituted complex [MoO2(acac)
(L2)] (3) could be isolated in 34% yield which could not be
improved with excess ligand (Scheme 3). NMR spectroscopy
clearly features resonances for one iminophenolate and one
acetylacetonate ligand.

The moisture sensitive complexes 1–3 are well soluble in
most organic solvents including aliphatic hydrocarbons. Spec-
troscopic data (1H, 13C NMR and FT-IR spectroscopy), elemen-
tal analyses as well as single-crystal X-ray diffraction analyses
confirm their structures.

OAT reactivity of complexes 1–3

The reaction of Mo(vi) dioxido compounds 1 or 2 with excess
PMe3 (5 equiv.) led to phosphane coordinated Mo(vi) oxido

![Scheme 3](image)

Scheme 3 Synthesis of monosubstituted complex 3.

compounds 4 and 5 in very good yields (Scheme 4). Similar to
the 1H NMR resonances for 1 and 2, also for these oxido phos-
phane compounds two distinct species are observed in solu-
tion, reflected by two sets of resonances for two non-
equivalent arranged ligands each. For both isomers, the co-
ordinated PMe3 molecule gives rise to a distinct resonance in
the decoupled 31P NMR spectra of 4 and 5.

The isomeric ratios for the oxido phosphane complexes are
found to be 9 : 1 (4) and 3 : 1 (5), thus revealing a significant
shift in the isomeric ratio for 4 in comparison with 1 (ratio
3 : 1), whereas the isomeric ratio for 5 is in a similar range
than for 2 (ratio 3 : 2). As all possible isomers exhibit non-equi-
valent ligand surroundings, routine NMR spectroscopy does
not allow for the determination of specific isomers. However,
we were able to obtain single-crystals suitable for X-ray diffrac-
tion analysis of 5, which revealed it to be the O,O isomeric
form (type B, Fig. 1) depicted in Scheme 4.

This is in contrast to the solid state structures of 1 and 2
which displayed the N,N isomeric form (type A, Fig. 1) and
points towards an isomeric rearrangement during the trans-
formation of 2 to 5. The rearrangement is likely caused by
higher steric demand of the phosphane ligand, which is cor-
norated by the exclusive O,O isomeric structure of a previously
reported system featuring ligands with high steric demand
(R = tBu).16 Dissolution of single crystals and immediate rec-
ording of a 1H NMR spectrum showed an isomerically pure
compound and allowed for the identification of the major isomer
in solution as the O,O isomeric form. Interestingly, a 1H NMR
spectrum of the same sample after 24 h still showed only reso-
nances corresponding to the O,O isomer, accompanied by
traces of oxidized complex 9. This suggests that the two
isomers found for 5 are not in a dynamic equilibrium or equi-
librate only slowly. Whereas similar unambiguous evidence via
the solid state structure cannot be provided for compound 4,
we assume that it exhibits similar properties, especially due to

![Scheme 4](image)

with isomeric ratios for complexes 4 and 5. For clarity, only one possible
isomer is depicted for all complexes.
the observation of the O,O structural motif in the molecular structure of both corresponding oxido peroxido compounds 8 and 9 (vide infra).

The reactions of dioxido compounds 1 and 2, respectively, with the more bulky PPh3 or with stoichiometric amounts of PMe3 led to species 6 and 7 in good yields (Scheme 4). Proton NMR spectroscopy reveals two sets of ligand resonances for 6 and 7 corresponding to a non-equivalent arrangement of the ligands, furthermore both compounds adopt a single isomer in solution. Neither 6 nor 7 shows any resonances in the 31P NMR spectra and both are thus phosphane free. Single-crystal X-ray diffraction analysis of 6 identified the compound as a μ-oxido bridged dinuclear oxidomolybdenum(v) complex as shown in Scheme 4, complex 7 being likely of a similar structure. The reaction of the monosubstituted complex 3 with PMe3 or PPh3, respectively, led to the formation of several unidentified products.

Complexes 4 and 5 are very well and complexes 6 and 7 are well soluble in organic solvents including aliphatic hydrocarbons. Whereas 4 and 5 are highly sensitive towards air and moisture, 6 and 7 are stable towards air and traces of moisture. In solution, 4 and 5 tend to decompose within hours (4) to days (5). The compounds were characterized via 1H, 13C, 31P NMR and FT-IR spectroscopy as well as elemental analyses, confirming their structures. Complexes 5 and 6 have additionally been characterized via single-crystal X-ray diffraction analysis (vide infra).

Activation of molecular dioxygen

Complexes 4 and 5 cleanly reacted with molecular dioxygen, indicated by a quick color change from red-brown to orange-red, to form oxido peroxido compounds 8 and 9 in excellent yields (Scheme 5). Compound 8 is alternatively accessible in a one-pot reaction from 1 via the addition of excess PMe3 (1 M solution in toluene) and subsequent stirring overnight under an O2 atmosphere, similar to a previously reported procedure.16 Compounds 6 and 7 were virtually non-reactive toward molecular oxygen under ambient conditions.

Exposure of 6 and 7 to molecular oxygen at 80 °C led to the formation of a mixture of dioxido and oxido peroxido complexes 1/8 and 2/9, respectively, accompanied by severe decomposition to free ligands and NMR inactive species. The reaction of 6 or 7 with O2 requires a preceding disproportionation reaction forming Mo(ν)O (and Mo(ν)O2), which is corroborated by the necessity of high temperatures and the resulting product mixture.

Whereas, in contrast to complexes 1, 2, 4 and 5, compound 8 exists as single isomer in solution, as evidenced by 1H and 13C NMR spectroscopy, complex 9 also exists as a mixture of two isomers in solution in an approximate ratio of 4:1.

Similar to the solid state structure of 5, both oxido peroxido compounds were identified as the O,O isomer (type B, Fig. 1) via single-crystal X-ray diffraction analysis. It is feasible to assign the O,O form to the structure of 8 also in solution because only a single isomer is observed. Dissolution of single crystals of 9 and immediate recording of a 1H NMR spectrum showed only resonances for one species, which we thus also assign to the O,O isomer. Interestingly, a 1H NMR spectrum of the same sample after 24 h revealed the initial isomeric ratio of 4:1 pointing towards a (slow) dynamic equilibrium as previously observed in molybdenum(vi) isocyanide complexes.23 Comparing the structure of the oxido peroxido compounds 8 and 9 with previously published cis oxido peroxido complexes originating from O2 activation, it is evident that the O2 isomic form is the preferred conformation for such compounds in the solid state.6,15,16 Complexes 8 and 9 are well soluble in most organic solvents and soluble in aliphatic hydrocarbons. Both complexes are stable towards air but sensitive towards moisture.

Catalytic oxidation of phosphanes

Complexes 1 and 2 were tested for their ability to catalyze the aerobic oxidation of phosphanes, namely trimethyl phosphane and triphenyl phosphane, according to Scheme 6. The conditions used were 1 mol% catalyst with an excess of dry O2 gas (1.5 atm) in C6D6 at room temperature. Blank experiments under identical conditions but without catalysts led to conversions of PMe3 and PPh3 to <5%. In the aerobic oxidation of PMe3, catalyst 1 was found to be significantly more active compared to 2 (65 vs. 35% conversion, Table 1) and more active than the previously described tert-butyl based system (19%).16 Catalyst 2 proved to be unsuitable as only 25% of OPMeto was formed together with 10% of one side product. NMR spec-

Scheme 5 Activation of molecular oxygen to form oxido peroxido compounds 8 and 9.

Scheme 6 Molybdenum(vi)-catalyzed aerobic oxidation of phosphanes, [Mo] = 1 or 2.
troscopy revealed it to be methyl dimethylphosphinate (OP-
(OMe)Me2) where an additional oxygen atom was inserted into one P–C bond (Fig. S37 and 38†). This is highly interesting as it demonstrates for the first time the transfer of two oxygen atoms from a molybdenum oxido peroxido species to one substrate molecule.

In contrast, PPh3 was oxidized selectively to OPPh3 by 2, but only 23% was converted. Interestingly, catalyst 1 was virtually non-reactive for the oxidation of PPh3 (8%). To our further understanding of this reactivity difference, we subsequently tested the dimeric complexes 6 and 7 in the catalytic oxidation of PPh3. Phenyl-based compound 7 led to a fourfold higher yield of OPPh3 (12% vs. 3%) in comparison with methoxy-propylene based complex 6. This is in good agreement with the activity difference of 1 and 2 in the aerobic oxidation of PPh3 and suggests lower activation energy for the disproportionation of 7, a requirement for reactivity with O2, in comparison with 6. The temperature increase in the catalytic oxidation of PPh3 was tested but due to significant autooxidation at 50 °C, as observed in a blank experiment, no reliable results could be obtained. To confirm the participation of the [MoO-
(O2)L2] species in the catalytic oxidation, we reacted complex 9 with 2 equiv. of PMe3 in a control experiment. Proton NMR measurement after 6 h of reaction time showed a mixture of 9 and the phosphane complex 5 together with OPMe3 and residual PMe3 but no dioxido species 2 (Fig. S45†). These results confirm the oxidation capability of complex 9 and are in good agreement with previous observations.16

Molecular structures
The molecular structures of molybdenum(vi) dioxido complexes 1–3, molybdenum(iv) oxido phosphane complex 5, molybdenum(v) oxido µ-oxido complex 6 as well as molybdenum(vi) oxido peroxido complexes 8 and 9 were determined by single-crystal X-ray diffraction analysis. The molecular views of 1–3 are given in Fig. 2, those of 5 and 6 in Fig. 3, and those of 8 and 9 in Fig. 4. Selected bond lengths and angles for com-

For disordered fragments, only atoms with the higher site occupation factors are depicted. In complex 6, only atoms in the asymmetric unit are labelled.
Arrangement corresponds to the N,N isomer (type coordinated by two iminophenolate ligands, the ligand as well as one acetylacetonate oxygen is trans ligands. The molybdenum oxido bond lengths observed in a distorted octahedral fashion by two bidentate ligands and oxido ligands, respectively, which correspond to the O,O bond length is 2.5289(6) Å, thus both are rather long but comparable to previously structurally characterized peroxido compounds, the Mo(V) oxido peroxido ligands, a terminal oxido ligand as well as the μ-oxido ligand in a distorted octahedral fashion. The complex is symmetric around the bridging oxido ligand with a Mo1–O2–Mo1 angle of 157.2(5)° as well as twisted about the Mo1–...Mo1’ connecting line (O1–Mo1–...Mo1−O1’ −31.1(3)°, N1–Mo1–...Mo1−N2−42.8(3)°), rendering the two terminal oxido ligands in a gauche-like conformation in the solid state. The arrangement of the ligands around the metal centers resemble the O,O isomer (Fig. 1) with the phenolate oxygens trans to the oxido and μ-oxido ligands, respectively. The Mo=O and Mo–(μ-O) bond lengths are within the expected ranges (Table 2).

Compound 6, obtained via OAT from 1 to PPh3 displays a μ-oxido bridged dimeric structure with two molybdenum(ν) oxido metal centers each coordinated by two bidentate ligands, a terminal oxido ligand as well as the μ-oxido ligand in a distorted octahedral fashion. The complex is symmetric around the bridging oxido ligand with a Mo1–O2–Mo1′ angle of 157.2(5)° as well as twisted about the Mo1–...Mo1′ connecting line (O1–Mo1–...Mo1−O1′ −31.1(3)°, N1–Mo1–...Mo1−N2−42.8(3)°), rendering the two terminal oxido ligands in a gauche-like conformation in the solid state. The arrangement of the ligands around the metal centers resemble the O,O isomer (Fig. 1) with the phenolate oxygens trans to the oxido and μ-oxido ligands, respectively. The Mo=O and Mo–(μ-O) bond lengths are within the expected ranges (Table 2).

Compounds 8 and 9 are coordinated by two bidentate iminophenolate ligands, a terminal oxido ligand and a η1 side-on coordinated peroxido ligand in a distorted octahedral fashion. Both compounds adopt the O,O isomeric form in the solid state, with the phenolate oxygen atoms trans to the oxido and peroxido ligands, respectively. Whereas the Mo=O bond lengths for 8 and 9 as well as the Mo–O (peroxido) bond lengths in 9 are similar to previously reported Mo(ν) oxido peroxido compounds, the Mo–O (peroxido) distances in 8 are

Conclusions

The reaction of functionalized iminophenolic ligands with molybdenum(vi) metal precursors [MoO₂Cl₂] and [MoO₂Cl₂(DME)] yielded disubstituted complexes 1 and 2, whereas the use of [MoO₄(acac)₂] as a metal source led to monosubstituted complex 3 coordinated by one iminophenolate and one acac⁻ moiety. Subsequent oxygen atom transfer from 1 or 2 to phosphines gave rise to distinct molybdenum(vi) and molybdenum(v) complexes. The products obtained from the reactions of 1 and 2 were dependent on the nature of the phosphine (PMe₃ or PPh₃) as well as the employed stoichiometry. The use of excess of PMe₃ yielded molybdenum(vi) oxido phosphane complexes 4 and 5. Upon the use of stoichiometric amounts of PMe₃ or PPh₃, molybdenum(v) μ-oxido complexes 6 and 7 were obtained. Compounds 4 and 5 readily reacted with molecular oxygen under ambient conditions to give oxido peroxyido complexes 8 and 9, while 6 and 7 did not show similar reactivity. Complexes 1, 2, 4, 5 and 9 exist as isomeric mixtures in solution, but for 8 only one isomer is observed.

Furthermore 1 and 2 adopt a different ligand arrangement than 5, 6, 8 and 9 in the solid state. A comparison of Mo–N and Mo–O bond lengths within the solid state structures of 1, 2, 5, 6, 8 and 9 reveals a significant impact of the oxido trans influence on the bonding situation in these complexes. Dioxo molybdphenoxide(vi) complexes 1 and 2 have been found to catalyze the aerobic oxidation of PMe₃ and PPh₃ with noteworthy reactivity differences depending on the nature of the ligand. In the oxidation of PMe₃, compound 1 was significantly more active and selective in comparison with 2, however 2 marked the first example of a catalyst capable of transferring both peroxy oxygen atoms to one substrate molecule and thus partially oxidizing trimethyl phosphate to methyl di-methylphosphinate (OP(OMe)Me₂). In the catalytic aerobic oxidation of PPh₃, complex 1 proved to be virtually unreactive whereas complex 2 gave significant yields of OPPh₃. In the case of PMe₃ oxidation, the active site is coordinated by a substrate molecule. Thus, prior elimination of PMe₃ is necessary, occurring readily under O₂ which we have recently demonstrated. It is not possible with the more bulky PPh₃ as evidenced by the formation of dinuclear μ-oxido bridged complexes in stoichiometric reactions. However, catalysis experiments using these dimeric compounds 6 and 7 as catalysts in the oxidation of PPh₃ showed the phenyl-based dinuclear compound 7 exhibiting catalytic activity whereas 6 was completely inactive. This indicates lower activation energy for the disproportionation of 7, which is required for the reaction with molecular O₂, in comparison with compound 6. The results presented herein provide further understanding of the species involved in OAT reactions as well as oxygen activation with molybdenum(vi)/(vii) systems and also insight into the diverse effects of ligand functionalization on the reactivity of such systems.

Experimental section

General

Unless specified otherwise, experiments were performed under inert conditions using standard Schlenk equipment. Commercially available chemicals were purchased from Sigma-Aldrich and used as received. No further purification or drying operations have been performed. The metal precursors [MoO₄(acac)₂] and [MoO₂Cl₂(DME)] were synthesized according to known procedures. Solvents were purified via a Pure-Solv MD-4-EN solvent purification system from Innovative Technology, Inc. Methanol was refluxed over activated magnesium for at least 24 h and then distilled prior to use. The ¹H, ¹³C and ³¹P NMR spectra were recorded on a Bruker Optics instrument at 300/75/121 MHz. The peaks are denoted as singlet (s), broad singlet (bs), doublet (d), doublet of doublets (dd), triplet (t), pseudo-doublet (“dd”), pseudo-triplet (“t”) and multiplet (m). The used solvents and peak assignment are mentioned in the specific data sets. Resonances in ³¹P NMR were referenced to phosphoric acid as an external standard. Electron impact mass spectroscopy (EI-MS) measurements have been performed with an Agilent 5973 MSD mass spectrometer with a push rod. ESI-MS as well as HR-MS (ESI⁺) measurements were performed at the University of Graz, Department of Analytical Chemistry. ESI measurements were performed using an Agilent 1100 Series LC/MSD (SL type), HR-MS (ESI⁺) measurements were performed using a Thermo Scientific Q-Exactive mass spectrometer in positive ion mode, and the used solvent was acetonitrile. The peaks are denoted as cationic mass peaks, and the unit is the according ion mass/charge ratio. Solid samples for infrared spectroscopy were measured on a Bruker Optics ALPHA FT-IR Spectrometer. Liquid samples were recorded in benzene on a Bruker FT-MIR matrix MF in situ spectrometer using a glass fiber optic probe.
The IR bands are reported with wavenumber (cm⁻¹) and intensities (s, strong; m, medium; w, weak). All elemental analyses were performed at the Technical University of Graz, Institute of Inorganic Chemistry using a Heraeus Vario Elmerar automatic analyzer.

X-ray diffraction analyses

Single-crystal X-ray diffraction analyses were performed on a BRUKER-AXS SMART APEX II diffractometer equipped with a CCD detector. All measurements were performed using monochromatized Mo Kα radiation from an Incoatec microfocus sealed tube at 100 K (cf. Table S1†). Absorption corrections were performed semi-empirical from equivalents. The structures were solved by direct methods (SHELXS-97)²⁷ and refined by full-matrix least-squares techniques against F² (SHELXL-2014/6).²⁷ CCDC 1476035-1476040 and 1486756 contain the supplementary crystallographic data for this paper. Full experimental details for single-crystal X-ray diffraction analyses of all compounds are provided in the ESI.†

Ligand synthesis

All ligands are stable towards air and moderately stable towards moisture. They can be stored in a desiccator over P₂O₅ for several weeks without decomposition.

Synthesis of (E)-2,4-di-tert-butyl-6-((3-methoxypropylimino)methyl)phenol (HL1).十八 Ligand HL1 was prepared following published procedures. In brief, 3-methoxy-1-propylamine (1.25 g, 14.0 mmol) was added to a solution of 3,5-di-tert-butyl-2-hydroxybenzaldehyde (3.28 g, 14.0 mmol) in 50 mL of MeOH and the resulting yellow solution was stirred at reflux temperature overnight. The reaction solution was subsequently dried over MgSO₄ and the solvent was evaporated in vacuo to give HL1 as a yellow oil (95%, 4.05 g). Analytical data is in compliance with the literature, and the ¹H NMR shifts in C₆D₆ as reported.

Synthesis of (E)-2,4-di-tert-butyl-6-((phenylimino)methyl)phenol (HL2).十九 Ligand HL2 was prepared following published procedures. In brief, aniline (0.92 mL, 10.0 mmol) was added to a solution of 3,5-di-tert-butyl-2-hydroxybenzaldehyde (2.34 g, 10.0 mmol) in 25 mL of MeOH and the resulting yellow solution was stirred at reflux temperature overnight. The reaction mixture was subsequently cooled to room temperature and filtered. The precipitate was dried in vacuo to yield HL2 as an orange crystalline solid (89%, 2.75 g). Analytical data is in compliance with the literature, and the ¹H NMR shifts in C₆D₆ as well as IR bands are given for the purpose of comparison.

Complex syntheses

All complexes are sensitive towards moisture; complexes 4 and 5 are additionally highly sensitive towards air. They can be stored in an N₂-filled glovebox for several weeks without decomposition.

Synthesis of [MoO₂(L1)₂] (1). For the synthesis of 1, 2 equiv. of HL1 (460 mg, 1.50 mmol) were dissolved in a small portion of dry toluene and slowly added to a solution of 1 equiv. [MoO₂Cl₂(DME)] (220 mg, 0.75 mmol) in the same solvent (5 mL). Subsequently 2.4 equiv. Et₂N (255 μL, 1.81 mmol) were added via syringe. The orange reaction mixture was stirred overnight and then filtered through a glass frit packed with Celite. The solvent was removed in vacuo to afford a waxy product which was thoroughly washed with cold dry pentane to obtain pure 1 as a bright yellow solid (81%, 450 mg). Crystals suitable for single-crystal X-ray diffraction analysis were obtained via recrystallization from a concentrated THF solution layered with pentane at room temperature. ¹H NMR (300 MHz, C₆D₆, 25 °C, N,N isomer) δ: 7.99 (s, 2H, CH=N), 7.71 (d, 2H, ArH), 7.09 (d, 2H, ArH), 3.63–3.58 (m, 4H, CH₂), 3.16–3.09 (m, 2H, CH₂), 303–2.99 (m, 2H, CH₂), 2.92 (s, 6H, OMe), 2.00–1.92 (m, 4H, CH₂), 1.29 (s, 18H, tBu), 1.27 (s, 18H, tBu) ppm; ¹³C NMR (75 MHz, C₆D₆, 25 °C, N,N isomer) δ: 168.04 (CH=N), 160.98 (Ar-O), 142.08, 139.58, 129.74, 128.19 (HSQC), 122.19 (Ar), 69.48 (CH₂), 58.11 (OMe), 57.36 (CH₂), 53.65, 34.38 (q-tBu), 31.60, 31.56 (tBu), 31.30 (CH₃) ppm; IR (ATR, cm⁻¹) ν: 1628 (s), 1592 (w), 1460 (w), 1247 (s), 1108 (s), 1047 (w), 913 (m), 902 (s), 841 (s), 549 (s); EI-MS (70 eV) m/z: 738.6 [M⁺]; Anal. calcd for C₆H₆₆MoN₀₂O₆: C, 61.94; H, 8.21; N, 3.80; found: C, 61.62, H, 8.09; N, 3.78%.

Synthesis of [MoO₂(L2)₂] (2). For the synthesis of 2, 2 equiv. of HL2 (311 mg, 1.01 mmol) were dissolved in a small portion of dry toluene and slowly added to a suspension of 1 equiv. [MoO₂Cl₂(DME)] (100 mg, 0.51 mmol) in the same solvent (3 mL). Subsequently 2.4 equiv. Et₂N (168 μL, 1.21 mmol) were added via syringe. The dark red reaction mixture was stirred overnight whereupon a yellow solid was precipitated. The precipitate was washed twice with dry pentane, loaded onto a glass frit packed with Celite and eluted with dry Et₂O until the eluent turned colorless. The solution was evaporated and the residual waxy orange solid was recrystallized from dry MeCN at ~35 °C to yield 2-MeCN as a dark yellow microcrystalline solid (65%, 389 mg). Crystals suitable for single-crystal X-ray diffraction analysis were obtained via slow evaporation of a concentrated MeCN solution at ~35 °C. ¹H NMR (300 MHz, C₆D₆, 25 °C, O, N isomer) δ: 7.68 (d, 1H, ArH), 7.66 (d, 1H, ArH), 7.56 (s, 1H, CH=N), 7.44–7.41 (m, 2H, ArH), 7.41 (s, 1H, CH=N), 7.20–7.16 (m, 1H, ArH), 7.09–7.00 (m, 1H, ArH), 6.90–6.75 (m, 7H, ArH), 6.64 (d, 1H, ArH), 1.70 (s, 9H, tBu), 1.49 (s, 9H, tBu), 1.26 (s, 9H, tBu), 1.23 (s, 9H, tBu); ¹³C NMR (300 MHz, C₆D₆, N isomer) δ: 7.88 (s, 2H, CH=N), 7.58 (d, 2H, ArH), 7.09–7.00 (m, 4H, ArH), 6.90–6.75 (m, 8H, ArH), 1.37 (s, 18H, tBu), 1.24 (s, 18H, tBu); ¹³C NMR (HSQC 300/75 MHz, C₆D₆, 25 °C, O,N
isomer, q-C obscured) δ: 170.13, 165.54 (CH=–N), 131.70, 129.59, 129.26, 128.97, 128.98, 127.95, 126.50, 126.00, 125.72, 125.67, 125.54, 123.26, 123.18, 123.06 (Ar), 31.21, 31.20, 29.85 (tBu); 13C NMR (HSQC 300/75 MHz, C6D6, 25 °C, N,N isomer, q-C obscured) δ: 169.00 (CH=N), 130.20, 128.91, 128.73, 128.58, 128.48, 123.18 (Ar), 31.21, 29.82 (tBu); IR (ATR, cm⁻¹): 2956 s, 1611 s, 1592 s, 1559 w, 1486 w, 1437 w, 1272 m, 1253 s, 1177 s, 928 w, 910 s, 897 s, 845 m, 765 m, 705 w, 554 w; EI-MS (70 eV) m/z: 746.6 [M⁺]; Anal. calcéd for C18H24MoNO3P: C, 67.93; H, 7.63; N, 3.52; found: C, 67.91; H, 7.65; N, 3.51.

**Synthesis of [MoO₂(acac)₂] (3).** For the synthesis of 3, 2 equiv. of HLL2 (380 mg, 1.23 mmol) were added to a suspension of [MoO₂(acac)₂] in dry MeCN (5 mL). The resulting orange reaction solution was then stirred at 80 °C overnight and subsequently evaporated in vacuo. The resulting oily orange product was then washed with dry pentane (10 mL) and sonicated. The supernatant was then washed via column filtration and the yellow residue was washed twice with 5 mL of dry pentane. Recrystallization of the residue from dry MeCN yielded 3 as bright yellow crystals (34%, 121 mg). Crystals suitable for single-crystal X-ray diffraction analysis were obtained via slow evaporation of a concentrated MeCN solution at ~35 °C. 1H NMR (300 MHz, C6D6, 25 °C) δ: 7.71 (d, 1H, ArH), 7.65 (s, 1H, CH=N), 7.15–7.12 (m, 2H, ArH), 7.01–6.88 (m, 4H, ArH), 4.83 (s, 1H, CH), 1.65 (s, 9H, tBu), 1.44 (s, 3H, Me), 1.26 (s, 9H, tBu), 1.13 (s, 3H, Me) ppm; 13C NMR (300 MHz, C6D6, 25 °C) δ: 195.26, 185.83 (C=O), 166.81 (CH=N), 159.17 (Ar-O), 152.24, 142.66, 140.51, 130.47, 129.36, 128.45, 126.23, 123.91, 121.96 (Ar), 103.55 (CH), 35.75, 34.42 (q-tBu), 31.53, 30.09 (tBu), 27.27, 24.90 (Me) ppm; IR (ATR, cm⁻¹) δ: 2962 m, 1605 (m), 1518 (s), 1362 (m), 1275 (m), 1250 (m), 1177 (m), 928 (s), 912 (s), 848 (s), 794 (m), 762 (s), 695 (m), 568 (s), 450 (s); El-MS (70 eV) m/z: 537.3 [M⁺]; Anal. calcéd for C27H22MoNO4O3P: C, 65.82; H, 6.21; N, 2.62; found: C, 58.15, H, 6.04; N, 2.68.

**Synthesis of [MoO(PMe₃)(L1)₂] (4).** For the synthesis of 4, a solution of 1 equiv. of 1 (103 mg, 0.14 mmol) in dry toluene was treated with 5 equiv. PMe₃ (70 µl, 0.70 mmol) in toluene at room temperature. The reddish brown solution was stirred at room temperature for 1 h, whereupon the solvent was evaporated in vacuo. The crude residue was re-dissolved in little cold dry heptane and filtered through a glass frit packed with Celite. Evaporation of all volatiles gave 4 as a dark red-brown solid material (81%, 93 mg). Crystals suitable for single-crystal X-ray diffraction analysis were obtained via slow evaporation of a concentrated MeCN solution at ~35 °C. HR-MS (ESI⁺) m/z: 866 (m), 764 (m), 704 (m), 694 (m), 637 (w), 523 (s), 448 (w); 13C NMR (75 MHz, C6D6, 25 °C, O,O isomer) δ: 170.14 (CH=–N), 166.47 (Ar-O), 163.63 (CH=N), 163.08 (Ar-O), 160.20, 157.97, 140.84, 138.73, 136.91, 136.67, 131.89, 131.16, 130.59, 129.28 (2×), 128.65, 128.03 (2×, HSQC), 126.57, 125.92, 124.85 (2×), 123.69 (2×), 121.44 (Ar), 35.67, 35.53, 34.28, 34.04 (q-tBu), 31.82, 31.68, 30.15, 29.99 (tBu), 15.39 (d, PMe₃) ppm; 31P NMR (121 MHz, C6D6, 25 °C) δ: −0.77 (O,O isomer, Mo-PMe₃), −1.99 (putative O,N isomer, Mo-PMe₃) ppm; IR (ATR, cm⁻¹) δ: 2949 (m), 1601 (m), 1587 (m), 1527 (m), 1485 (m), 1254 (m), 1165 (s), 953 (w), 927 (s), 866 (m), 764 (m), 704 (m), 694 (m), 637 (w), 523 (s), 448 (w); HR-MS (ESI⁺) m/z: [M⁺] calcéd for C₄₅H₆₁MoN₂O₃P: 806.3474, found: 806.3474; Anal. calcéd for C₄₅H₆₁MoN₂O₃P: C, 67.15; H, 7.64; N, 3.48; found: C, 67.60; H, 7.43; N, 3.35.

**Synthesis of [MoO(L1)][µ-O] (6).** For the synthesis of 6, a solution of 1 equiv. 1 (103 mg, 0.14 mmol) in dry toluene (3 mL) was treated with 2 equiv. of PMe₃ (29 µl, 0.28 mmol). The addition resulted in a quick color change from orange to dark red. The solution was then stirred for 1 h at room temperature, subsequently the solvent was removed in vacuo whereupon the crude product was re-dissolved in cold dry heptane (5 ml) and filtered through a glass frit packed with Celite. After concentration of the solution to ~2 mL, inert column chromatography on basic aluminum oxide with dry ether/pentane (1:1) as the eluent was performed and the first red band was collected. Evaporation of the solvent gave 6 as a dark red solid (68%, 69 mg). For elemental analyses, the complex was recrystallized from dry CH₂Cl₂. Alternatively, complex 6 is accessible by OAT from complex 1 (100 mg, 0.14 mmol, 1 equiv.) to PPH₃ (37 mg, 0.14 mmol, 1 equiv.) in dry toluene (5 mL). After stirring for 24 h at room temperature, purification was followed the procedure described above. Residual traces of PPH₃ were first eluted from the basic aluminum oxide column with pentane.
The use of polymer-bound PPh₃ led to insoluble by-products and thus a simplified work-up procedure. Crystals suitable for single-crystal X-ray diffraction analysis were obtained by slow evaporation of a concentrated MeCN solution at ~35 °C. 

$^1$H NMR (300 MHz, C₆D₆, 25 °C) δ: 8.26 (s, 2H, CH=–N), 8.10 (s, 2H, CH=–N), 7.57 (d, 2H, ArH), 7.46 (d, 2H, ArH), 7.02 (d, 2H, ArH), 6.84 (d, 2H, ArH), 5.04–4.97 (m, 2H, CH₂), 4.62–4.52 (m, 2H, CH₂), 4.39–4.30 (m, 2H, CH₂), 3.69–3.60 (m, 2H, CH₂), 3.42–3.24 (m, 4H, CH₂), 3.11–3.05 (m, 2H, CH₂), 3.02 (6, H, OMe), 2.92 (s, 6H, OMe), 2.78–2.47 (m, 8H, CH₂), 2.10–1.92 (m, 2H, CH₂), 1.41 (s, 18H, tBu), 1.31 (s, 18H, tBu), 1.22 (s, 18H, tBu), 1.19 (s, 18H, tBu) ppm; ¹³C NMR (75 MHz, C₆D₆, 25 °C) δ: 169.91 (C13 (CH=–N)), 166.94, 165.27 (Ar–O), 140.01, 139.28, 138.48, 137.47, 131.62, 129.69, 128.85, 121.95, 121.87 (Ar), 70.26, 70.08, 61.30, 60.77 (CH₂), 58.35, 58.20 (OMe), 35.51, 35.23, 34.15, 33.99 (q-tBu), 33.25, 31.95 (CH₃), 31.32, 31.44, 29.81, 29.46 (tBu) ppm; IR (ATR, cm⁻¹) δ: 1611 (s), 1579 (s), 1256 (s), 1104 (br, s), 1014 (br, s), 928 (s), 798 (br, s), 529 (s); El–MS (70 eV) m/z: 722.6 [MoO(L)⁺]⁺; Anal. calcd. for C₇₆H₁₂₄Mo₂N₄O₁₀·CH₂Cl₂: C, 59.80; H, 8.21; N, 3.62; found: C, 59.94; H, 8.40; N, 3.33%.

**Synthesis of [MoO(L₂)](µ–O) (7).** For the synthesis of 7, 1 equiv. of (100 mg, 0.13 mmol) and 1 equiv. of PPh₃ (34 mg, 0.13 mmol) were dissolved in dry MeCN (5 mL). The initially orange reaction solution was stirred at room temperature for 48 h whereupon it gradually darkened. The precipitate was subsequently filtered off, washed twice with little cold dry MeCN and dried in vacuo. After subsequent removal of the residual traces of PPh₃ and OPPh₃ via sublimation (110 °C, 2 × 10⁻⁵ atm), 7 was obtained as a dark purple solid (72%, 69 mg).

The use of polymer-bound PPh₃ led to insoluble by-products and thus a simplified work-up procedure. 

$^1$H NMR (300 MHz, C₆D₆, 25 °C) δ: 8.27 (s, 1H, CH=–N), 8.18 (s, 1H, CH=–N), 7.63 (d, 1H, ArH), 7.47 (d, 1H, ArH), 7.03 (d, 1H, ArH), 6.98 (d, 1H, ArH), 5.25–5.17 (m, 1H, CH₃), 5.01–5.94 (m, 1H, CH₃), 4.22–4.08 (m, 2H, CH₂), 3.59–3.52 (m, 1H, CH₃), 3.35–3.19 (m, 3H, CH₃), 3.04 (s, 3H, OMe), 3.01 (s, 3H, OMe), 2.60–2.29 (m, 4H, CH₃), 1.32 (s, 9H, tBu), 1.24 (s, 18H, tBu), 1.15 (s, 9H, tBu) ppm; ¹³C NMR (75 MHz, C₆D₆, 25 °C) δ: 169.00, 168.35 (CH=–N), 162.21, 160.64 (Ar–O), 139.70, 139.26, 139.06, 132.20, 131.67, 126.91, 129.28, 129.00, 121.93, 121.66 (Ar), 69.47, 69.39, 63.76, 59.68 (CH₃), 58.22, 58.19 (OMe), 35.06, 34.94 (q-tBu), 34.15 (2× q-tBu), 31.77 (CH₃), 31.60 (tBu), 31.53 (CH₃), 31.48, 29.73, 29.56 (tBu) ppm; IR (ATR, cm⁻¹) δ: 1612 (s), 1256 (s), 1108 (br, s), 1089 (br, s), 914 (s), 839 (s), 800 (s), 779 (s), 748 (m), 539 (s); ESI–MS (100 V) m/z: 755.3 [M⁺]; Anal. calcd. for C₇₆H₁₂₄Mo₂N₄O₁₀·0.2CH₂Cl₂: C, 59.60; H, 7.91; N, 3.64; found: C, 59.26; H, 7.99; N, 4.00%.

**Synthesis of [MoO₂(L₂)] (9).** For the synthesis of 9, a solution of 5 (100 mg, 0.12 mmol) in dry toluene (3 mL) was treated with excess dry O₂ gas whereupon the initially red-brown solution quickly turned deep orange. The solution was stirred under an O₂ atmosphere (1 atm) overnight at room temperature. Subsequently all volatiles were removed in vacuo. The resulting waxy dark orange residue was dissolved in a minimum amount of cold dry heptane and the resulting suspension was filtered through a glass frit packed with Celite. Evaporation of all volatiles in vacuo and subsequent sublimation of residual OPMe₂ traces (60 °C, 2 × 10⁻⁵ atm) gave 7 as a dark orange solid (85%, 84 mg). 

$^1$H NMR (300 MHz, C₆D₆, 25 °C, O,O isomer) δ: 8.11 (s, 1H, CH=–N), 8.10 (s, 1H, CH=–N), 7.89–7.85 (m, 2H, ArH), 7.70 (d, 1H, ArH), 7.61–7.56 (m, 2H, ArH), 7.54 (d, 1H, ArH), 7.24–7.18 (m, 2H, ArH), 7.13–6.99 (m, 4H, ArH), 6.90 (d, 1H, ArH), 6.86 (d, 1H, ArH), 1.37 (s, 9H, tBu), 1.26 (s, 9H, tBu), 1.25 (s, 9H, tBu), 1.23 (s, 9H, tBu) ppm; ¹³C NMR (HSQC 300/75 MHz, C₆D₆, 25 °C, q–c obscured) δ: 169.10, 168.74 (CH=–N), 133.20, 131.41, 130.24, 129.74, 128.81, 128.48, 126.48, 126.09, 127.15, 126.90, 125.44, 125.26 (Ar), 124.74 (2× Ar), 31.19, 30.99, 29.64, 29.54 (tBu); IR (ATR, cm⁻¹) δ: 2953 (m), 1611 (s), 1589 (s), 1540 (m), 1252 (s), 1172 (s), 927 (s), 838 (s), 765 (m), 704 (m), 692 (m), 538 (br s); HR–MS (ESI) m/z: [M + Na⁺] calcd for C₄₂H₂₅Mo₅N₇O₇: 785.2828, found: 785.2820; Anal. calcd for...
In a representative reaction, 5 mg of the respective catalyst (approx. 0.007 mmol) was dissolved in dry C₆D₆ under a N₂ atmosphere in a 50 mL Schlenk flask. Subsequently 100 equiv. of the respective phosphane (0.7 mmol PMe₃; 53 mg; PPh₃; 184 mg) were added to the solution. The Schlenk flask was then flushed with dry O₂ and placed under O₂ pressure (1.5 atm) whereupon the reaction solution was stirred for 24 h at room temperature. Subsequently the Schlenk flask was cooled to 0 °C and twice evacuated and backfilled with dry N₂. After addition of 0.2 mL of dry CD₃CN to ensure complete dissolution of all formed products, the reaction was monitored via 1H and 31P NMR spectroscopy, phosphane oxide yields were calculated via integration of the respective peak areas in the 1H NMR spectra, and conversion included the peak areas for the formed side product (OP(OMe)Me₂: 49.93). Blank experiments without catalysts were included for the formed side product (OP(OMe)Me₂: 49.93).

Acknowledgements

Financial support by the Austrian Science Fund (FWF) [grant number P26264] and NAWI Graz is gratefully acknowledged.
