Structure–antiproliferative activity studies on L-proline- and homoproline-4-N-pyrrolidine-3-thiosemicarbazone hybrids and their nickel(II), palladium(II) and copper(II) complexes†

Aliona Dobrova,‡a Sonja Platzer,‡a Felix Bacher,a Miljan N. M. Milunovic,a Anatolie Dobrov,b Gabriella Spengler,b Éva A. Enyedyc, Ghenadie Novitchid and Vladimir B. Arion*a

Two water-soluble thiosemicarbazone-proline (H2L1) and thiosemicarbazone-homoproline hybrids (H2L2) were synthesised. By reaction of H2L1 with NiCl2·6H2O, PdCl2 and CuCl2·2H2O in ethanol, the series of square-planar complexes [Ni(H2L1)Cl]Cl·1.3H2O (1·3H2O), [Pd(H2L1)Cl]Cl·H2O (2·H2O) and [Cu(H2L1)Cl]Cl·Cl·0.7H2O (3·0.7H2O) was prepared, and starting from H2L2 and CuCl2·2H2O in methanol, the complex [Cu(H2L2)Cl]·H2O (4·H2O) was obtained. The compounds have been characterised by elemental analysis, spectroscopic methods (IR, UV-vis and NMR spectroscopy), ESI mass spectrometry and single crystal X-ray crystallography (H2L1, 1, 2 and 4). As a solid, 1 is diamagnetic, while it is paramagnetic in methanolic solution. The effective magnetic moment of 3.26 B.M. at room temperature indicates the change in coordination geometry from square-planar to octahedral upon dissolution. The in vitro anticancer potency of ligand precursors H2L1 and H2L2 and metal complexes 1–4 was studied in three human cancer cell lines (AS49, CH1 and SW480) and in noncancerous murine embryonal fibroblasts (NIH/3T3), and the mechanism of cell death was also assayed by flow cytometry. Clear-cut structure–activity relationships have been established. The metal ions exert marked effects in a divergent manner: copper(ii) increases, whereas nickel(II) and palladium(ii) decrease the cytotoxicity of the hybrids. The antiproliferative activity of H2L1 and metal complexes 1–3 decreases in all three tumour cell lines in the following rank order: 3 > H2L1 > 1 > 2. The role of square-planar geometry in the underlying mechanism of cytotoxicity of the metal complexes studied seems to be negligible, while structural modifications at the terminal amino group of thiosemicarbazide and proline moieties are significant for enhancing the antiproliferative activity of both hybrids and copper(ii) complexes.

Introduction

α-(N)-Heterocyclic thiosemicarbazones (TSCs) are a class of highly potent inhibitors of the ribonucleotide reductase (RNR) enzyme.1,2 RNR catalyses the reduction of all four ribonucleotides to their corresponding deoxyribonucleotides and thereby provides the precursors needed for both synthesis and repair of DNA. Currently, the most studied therapeutic compound among the thiosemicarbazones is Triapine (3-aminopyridine-2-carboxaldehyde thiosemicarbazone). It is by a factor of 1000 a more potent inhibitor of hR2 RNR activity than hydroxyurea, a clinically used RNR inhibitor.3 Triapine has entered several phase II clinical trials as a chemotherapeutic agent.4 However, this investigational drug showed severe side effects, while only a small response was observed.5–8 Another promising drug, di-2-pyryldiketone 4-cyclohexyl-4-methyl-3-thiosemicarbazone (DpC), has just entered clinical trials,9 but RNR is not or only in part responsible for its biological activity.
Many thiosemicarbazones are excellent chelators for transition metal ions, such as iron(ii), copper(ii) and zinc(ii), typically coordinating via X, N, and S atoms, where X is the donor atom of the additional functional group of the aldehyde or ketone used for their preparation.\(^\text{10}\) The coordination of these TSCs can result in metal complexes with a higher cytotoxicity than that of the ligand precursors. In addition, the enhanced need for the essential metal ions of cancer cells vs. healthy cells makes the development of new chelators as anticancer agents an important task.\(^\text{11,12}\) Copper(ii) complexes are promising anticancer agents,\(^\text{13}\) often exhibiting very high antiproliferative activity in vitro. In particular, copper(ii) complexes with acyl diazine thiosemicarbazones bearing an N\(^4\)-azabicyclo[3.2.2]nonane group showed cytotoxic activity against colon adenocarcinoma HT-29 cells with IC\(_{50}\) values ranging from 4 nM to 1.51 \(\mu\)M and human acute lymphoblastic leukemia CCRF-CEM cells with IC\(_{50}\) values ranging from 5 nM to 1.16 \(\mu\)M.\(^\text{14}\)

Recently a series of copper(ii)-TSC complexes have been tested for their topoisomerase IIa inhibition activity with the conclusion that these complexes are more potent topoisomerase II\(\alpha\) inhibitors than the corresponding ligand precursors.\(^\text{15}\) One such copper(ii) complex was [Cu(L)], where HL = 2-pyridine-5-methylthiosemicarbazone. The main prerequisite for their topoisomerase II\(\alpha\) inhibition properties was suggested to be the square-planar coordination geometry of copper(ii) in these complexes.

Despite their high cytotoxicity in vitro, a low water solubility, high lipophilicity and high in vivo toxicity are the main disadvantages of TSC compounds as anticancer agents,\(^\text{16}\) so one of the current challenges is the design of new active TSCs and their metal complexes with enhanced aqueous solubility\(^\text{17}\) and a priori oriented towards a cancer specific target.\(^\text{18}\) We have shown that 2-hydroxybenzaldehyde thiosemicarbazone (STSC) can be coupled to \(\alpha\)- or \(\beta\)-proline (Pro) leading to hybrids with enhanced aqueous solubility.\(^\text{19}\) Although these new systems show only moderate cytotoxic potency with IC\(_{50}\) values of 62 and 75 \(\mu\)M, respectively, in ovarian carcinoma CH1 cells and >100 \(\mu\)M in colon carcinoma SW480 cells, the coordination of these ligands to copper(ii) resulted in a 13- and 5-fold increase in cytotoxicity in CH1 cells, based on a comparison of IC\(_{50}\) values, while in SW480 cells the enhancement of the antiproliferative activity was even higher. In both tested cell lines, \(\alpha\)-Pro-STSC as well as its copper(ii) complex showed slightly stronger antiproliferative activity than the compounds with a \(\beta\)-Pro moiety, yielding IC\(_{50}\) values of 4.6 and 5.5 \(\mu\)M for [Cu(\(\alpha\)-Pro-STSC)Cl]Cl in CH1 and SW480 cells, respectively.\(^\text{19}\) Moreover, the preliminary data from the screening of the topoisomerase II\(\alpha\) inhibiting activity indicate that the square-planar copper(ii) complexes prepared by us are indeed potential inhibitors of the topoisomerase II\(\alpha\) enzyme in contrast to the corresponding metal-free conjugates, which are devoid of such activity.

The quite recently reported results\(^\text{19}\) prompted us to prepare new 2-hydroxybenzaldehyde thiosemicarbazones substituted at the terminal nitrogen atom to enhance the lipophilicity and coupled to two related \(\alpha\)- and \(\beta\)-amino acid homologs, namely proline and homoproline. We anticipated that these new conjugates will form square-planar metal complexes enabling the elucidation of (i) the role of the square-planar coordination geometry of the metal complexes in the underlying mechanism of antiproliferative activity, (ii) the effect of metal coordination and (iii) substitution at the terminal nitrogen atom of the thiosemicarbazide moiety, and (iv) the effect of the homologisation of proline to \(\beta\)-homoproline on antiproliferative activity in cancer cell lines. Herein we report on the synthesis of two organic conjugates, namely 5-methyl-2-hydroxybenzaldehyde 4-N-pyrrolidine-3-thiosemicarbazone coupled to \(\alpha\)-proline and \(\beta\)-homoproline, respectively, and four new complexes with nickel(ii), palladium(ii) and copper(ii) (Chart 1), their characterisation by elemental analysis, spectroscopic methods, and X-ray crystallography, and their antiproliferative activity in three human cancer cell lines (A549, CH1 and SW480) and noncancerous murine fibroblasts (NIH/3T3). Clear-cut structure–activity relationships (SARs) were established and discussed.

### Experimental section

#### Chemicals

All reagents were used as purchased from commercial suppliers. \(\alpha\)-Proline was from Alfa Aesar. 4-Pyrrolidine-3-thiosemicarbazide\(^\text{20}\) was obtained in 60% yield by refluxing methyl hydrazinecarbodithioate\(^\text{21}\) and pyrrolidine in water for 6 h. 3-Chloromethyl-2-hydroxy-5-methylbenzaldehyde was synthesised by following a modified published procedure.\(^\text{22}\) Z-\(\beta\)-proline\(^\text{23}\) and \(\beta\)-homoproline\(^\text{24}\) were synthesised according to previously reported protocols. All utilised solvents were of HPLC grade and used without further purification.

#### Synthesis of ligand precursors

[1-(3-Formyl-2-hydroxy-5-methylbenzyl)-(R/S)-pyrrolidine-2-yl]acetic acid methyl ester. To a solution of 3-chloromethyl-2-hydroxy-5-methylbenzaldehyde (0.94 g, 5.09 mmol) in THF (10 mL) was added a solution of methyl (R/S)-pyrrolidin-2-yl-acetate (0.79 g, 5.59 mmol) in methylene chloride (5 mL) followed by a solution of triethylamine (1.09 mL, 7.64 mmol) in THF (2 mL) and the reaction mixture was stirred at 60 °C for 10 h. Then THF (100 mL) was added and the crystallised ethylammonium chloride was filtered off. The orange solution was concentrated under reduced pressure and purified by column chromatography by using a 1:1 mixture of ethyl acetate/hexane as the eluent (\(R_f = 0.14\)). The yellow oil was dried in vacuo. Yield: 1.18 g, 80.0%. \(^1\text{H NMR}\) (500.10 MHz, DMSO-d\(_6\)): \(\delta\) 10.24 (s, 1H, HC\(=O\)), 7.36 (d, \(J = 2.0\) Hz, 1H, Ar–H), 7.25 (d, \(J = 2.0\) Hz, 1H, Ar–H), 4.16 (d, \(J = 14.1\) Hz, 1H, Ar–CH\(_2\)-N), 3.60 (s, 3H, OCH\(_3\)), 3.54 (d, \(J = 14.2\) Hz, 1H, Ar–CH\(_2\)-N), 2.98–2.91 (m, 1H, Pyrr), 2.91–2.85 (m, 1H, Pyrr), 2.81–2.74 (m, 1H, Pyrr), 2.45 (dd, \(J = 7.6\) and 8.1 Hz, 2H, CH\(_2\)-COOMe), 2.33–2.27 (m, 1H, Pyrr), 2.24 (s, 3H, CH\(_3\)_), 2.08–2.00 (m, 1H, Pyrr), 1.76–1.67 (m, 3H, Pyrr), 1.61–1.53 (m, 1H, Pyrr) ppm. \(^{13}\text{C}({\text{H}})\) NMR (125.76 MHz, DMSO-d\(_6\)): \(\delta\) 191.78, 172.18, 159.25, 136.54, 128.19, 127.61, 125.57,
Upon cooling to room temperature, the precipitate was filtered (10 mL). The reaction mixture was refluxed at 85 °C for 1 h. Upon cooling to room temperature, the precipitate was filtered off, washed with cold ethanol (5 mL) and dried in vacuo overnight. Yield: 0.7 g, 25.2%; no m.p., decomposition without melting, onset at 180 °C. Anal. Caled for C_{19}H_{28}N_{4}O_{3}S·2H_{2}O (M 435.54 g mol⁻¹), %: C, 52.40; H, 7.17; N, 12.26; S, 7.36. Found, %: C, 52.29; H, 7.20; N, 12.70; S, 7.19. IR (ATR, selected bands, νmax): 3165, 3066, 2961, 2873, 1639, 1617, 1548, 1436, 1306, 1190, 961, 913, 751, 575 cm⁻¹. UV-vis in MeOH, λ, nm (ε, M⁻¹ cm⁻¹): 390 (1220), 334 (11350), 300sh (14000), 288 (16265), 249sh (10910), 227 (19380). ¹H NMR (500.10 MHz, DMSO-d₆): δ 11.24 (s, 1H, NH), 8.47 (s, 1H, HC=NC), 7.22 (s, 1H, Ar), 7.19 (s, 1H, Ar), 4.17 (d, J = 13.5 Hz, 1H, CH₂), 3.99 (d, J = 13.5 Hz, 1H, CH₂), 3.66 (s, 4H, proline or pyrrolidine), 3.56–3.52 (m, 2H, proline), 3.30–3.23 (m, 2H, proline), 2.85–2.77 (m, 1H, proline), 2.26 (s, 3H, CH₃), 2.21–2.12 (m, 1H, proline), 2.01–1.90 (m, 4H, pyrrolidine), 1.90–1.82 (m, 1H, proline), 1.75–1.65 (m, 1H, proline) ppm. ESI-MS in MeOH (positive): m/z 405.38 ([M + H]⁺). Calculated for C_{20}H_{28}N_{4}O_{3}S·2H_{2}O: m/z 405.20. ESI-MS in MeOH (negative): m/z 403.19 ([M − H]⁻). Calculated for C_{20}H_{28}N_{4}O_{3}S: m/z 403.18. UV-vis in MeOH, λ, nm (ε, M⁻¹ cm⁻¹): 335 (14.327), 300 (15.771), 288 (20.648), 227 (22.884). For the atom labeling scheme and assignment of NMR resonances see Chart 1.

**Synthesis of metal complexes**

[Ni(H₂L¹Cl)Cl·1.3H₂O (1.1₃H₂O)]. To a solution of H₂L¹·2H₂O (0.20 g, 0.47 mmol) in ethanol (20 mL) was added...
a solution of NiCl₂·6H₂O (0.12 g, 0.50 mmol) in ethanol (5 mL) and the reaction mixture was stirred at room temperature for 2 h. The solvent was removed on a rotary evaporator under reduced pressure. The residue was dissolved in methanol (2 mL) and the product precipitated by the addition of diethyl ether (20 mL) was filtered off, washed with diethyl ether (5 mL) and dried in air. Yield: 0.21 g, 82.2%; no m.p., decomposition without melting, onset at 260 °C. Anal. Calcd for C₃₆H₆₉Cl₂NiO₄S·3H₂O (M 543.52 g mol⁻¹), %: C, 41.99; H, 5.30; N, 10.31; S, 5.90; Cl, 13.05. Found, %: C, 41.82; H, 5.20; N, 10.49; S, 6.03; Cl, 13.30. IR (ATR, selected bands, νmax): 3204, 3108, 1733, 1598, 1450, 1360, 1215, 1180, 1155, 887, 862, 706, 603 cm⁻¹. UV-vis in MeOH, λ, nm (e, M⁻¹ cm⁻¹): 865 (135), 770 (45), 398 (33 100), 293 (38 900), 259 (62 300), 236 (69 600). ESI-MS in methanol (positive): m/z 447.26 [Ni(HL¹)⁺]. Calcd for C₁₀H₁₈NiClO₄S m/z 447.10. X-ray diffraction quality single crystals were grown by slow diffusion of diethyl ether into the solution of the complex in methanol. Magnetic susceptibility measurements indicate its diamagnetism in the solid state.

**[Pd[H₂L¹]Cl]Cl·2H₂O (2·H₂O).** To a solution of H₂L¹·2H₂O (0.20 g, 0.47 mmol) in ethanol (20 mL) was added a solution of PdCl₂ (0.09 g, 0.51 mmol) in ethanol (5 mL) and the reaction mixture was refluxed for 1 h. The solvent was removed on a rotary evaporator under reduced pressure. The residue was dissolved in methanol (2 mL) and the product precipitated by the addition of diethyl ether (20 mL) was filtered off, washed with diethyl ether (5 mL) and dried in air. Yield: 0.13 g, 47.2%; no m.p., decomposition without melting, onset at 220 °C. Anal. Calcd for C₃₈H₆₃Cl₂PdO₄S·H₂O (M 585.84 g mol⁻¹), %: C, 38.95; H, 4.82; N, 9.56; S, 5.47; Cl, 12.40. Found, %: C, 39.15; H, 4.43; N, 9.56; S, 5.70; Cl, 12.40. IR (ATR, selected bands, νmax): 3200, 3101, 1733, 1544, 1495, 1449, 1364, 1218, 1201, 1182, 1166, 863, 822, 600 cm⁻¹. UV-vis in MeOH, λ, nm (e, M⁻¹ cm⁻¹): 412 (22 340), 320 (31 575), 244 (60 220). H¹ NMR (500.10 MHz, DMSO-d₆): δ 9.99 (br, 1H, N²H), 8.31 (s, 1H, C¹¹H), 7.27 (d, J = 2.0, 1H, C¹H), 7.22 (d, J = 2.0, 1H, C¹H), 4.55–4.47 (m, 1H, C¹H), 4.42 (dd, J = 13.0, 5.0 Hz, 1H, C¹Hb), 4.31 (dd, J = 13.0, 5.0 Hz, 1H, C¹Hb), 3.64–3.55 (m, 1H, C¹²Hb), 3.53–3.47 (m, 2H, C¹¹Hb), 3.43–3.34 (m, 1H, C¹²Hb), 2.50–2.41 (m, 1H, C¹⁰Hb), 2.21 (s, 3H, C¹H), 2.11–1.98 (m, 2H, C¹⁰Hb + C¹¹Hb), 1.94–1.86 (m, 1H, C¹¹Hb) ppm. ¹³C NMR (126 MHz), δ 171.20, 170.35, 158.62, 146.79, 137.09, 135.24, 122.92, 120.03, 118.87, 66.01 (C¹H), 62.69, 55.95 (C¹¹H), 55.14 (C¹²H), 51.24 (C¹⁰H), 34.63, 28.42 (C¹Hb), 26.03 (C¹¹Hb), 22.86 (C¹¹Hb), 20.14 (C¹), 14.29 ppm. ESI-MS in methanol (negative): m/z 530.93 [M – HCl – H⁺].

**[Cu(H₂L¹)Cl]Cl·0.7H₂O (3·0.7H₂O).** To a solution of H₂L¹·2H₂O (0.20 g, 0.47 mmol) in ethanol (20 mL) was added a solution of CuCl₂·2H₂O (0.09 g, 0.53 mmol) in ethanol (5 mL) and the reaction mixture was stirred at room temperature for 2 h. The solvent was removed on a rotary evaporator under reduced pressure. The residue was dissolved in methanol (2 mL) and the product precipitated by the addition of diethyl ether (20 mL) was filtered off, washed with diethyl ether (5 mL) and dried in air. Yield: 0.15 g, 59.4%; no m.p., decomposition without melting, onset at 220 °C. Anal. Calcd for C₁₀H₁₄Cl₂CuN₄O₄S·0.7H₂O (M 537.56 g mol⁻¹), %: C, 42.45; H, 5.14; N, 10.42; S, 5.97; Cl, 13.19. Found, %: C, 42.30; H, 4.97; N, 10.24; S, 6.25; Cl, 13.54. IR (ATR, selected bands, νmax): 3178, 3083, 1742, 1582, 1481, 1462, 1445, 1394, 1361, 1347, 1259, 1179, 911, 821, 759, 700, 576 cm⁻¹. UV-vis in MeOH, λ, nm (e, M⁻¹ cm⁻¹): 635 (279), 403 (13 347), 333h (10 050), 311sh (21 397), 299 (29 236), 267 (18 430), 260sh (18 410). ESI-MS in methanol (positive): m/z 452 [Cu(HL¹)⁺].

**[Cu(H₂L²)Cl₄]Cl₂H₂O (4·H₂O).** To a solution of H₂L² (95 mg, 0.24 mmol) in methanol (10 mL) was added CuCl₂·2H₂O (44 mg, 0.26 mmol) in methanol (1 mL) and the reaction mixture was refluxed for 1 h. The green solution was concentrated to a volume of ca. 4 mL and allowed to stand at +4 °C for 6 h. The precipitate formed was filtered off, washed with diethyl ether (3 mL) and dried in vacuo. Yield: 70 mg, 55.1%; no m.p., decomposition without melting, onset at 210 °C. Anal. Calcd for C₁₀H₁₆Cl₂CuN₄O₄S·0.7H₂O (M 556.99 g mol⁻¹), %: C, 43.13; H, 5.43; N, 10.06; S, 5.76. Found, %: C, 43.03; H, 5.12; N, 9.68; S, 5.55. ESI-MS in MeOH (positive): m/z 466.18 ([Cu(H₂L²)⁺]).

**Crystallographic structure determination**

X-ray diffraction measurements of H₂L¹ and 1 were performed on a Bruker D8 Venture, while those of 2 and 4 were performed on Bruker X8 APEX CCD and STOE diffractometers, respectively, both equipped with an Oxford Cryosystem cooler device. The single crystals of H₂L¹, 1, 2 and 4 were positioned at 35, 35, 40 and 40 mm from the detector, and 1401, 1071, 636 and 2136 frames were measured, each for 20, 10, 20 and 38 s over 0.4, 0.5, 1 and 1° scan width, respectively. The data were processed using SAINT software. Crystal data, data collection parameters, and structure refinement details are given in Table 1. The structures were solved by direct methods and refined by full-matrix least-squares techniques. All non-hydrogen atoms were refined with anisotropic displacement parameters. H atoms were inserted in calculated positions and refined with a riding model. The pyrrolidine and proline rings in one of the two crystallographically independent molecules of 1 were found to be disordered over two positions with an s.o.f. of 0.65:0.35 and 0.75:0.25, respectively, without using any restraints implemented in SHELXL2014. SADI and EADP restraints were applied to resolve the static disorder observed in the co-crystallised solvent molecules in H₂L¹. The single crystal of 4 was weakly diffracting and the resolution of the collected X-ray data was estimated to be 1.02 Å. Nevertheless, the structure could be solved and the electron density of the molecule is well-defined, allowing for the determination of the atomic connectivity and refinement with anisotropic temperature factors for all non-hydrogen atoms. The following software...

Antiproliferative activity

CH1 cells (human ovarian carcinoma) were a generous gift from Lloyd R. Kelland, CRC Centre for Cancer Therapeutics, Institute of Cancer Research, Sutton, UK. SW480 (human adenocarcinoma of the colon) and A549 (human nonsmall cell lung cancer) cells were kindly provided by Brigitte Marian (Institute of Cancer Research, Department of Medicine I, Medical University of Vienna, Austria). NIH/3T3 (ATCC CRL-1658) murine embryonic fibroblasts were cultured according to the ATCC (American Type Culture Collection) protocol. All cell culture media and reagents were purchased from Sigma-Aldrich Austria and plastic ware from Starlab Germany. CH1, SW480, and A549 cells were grown in 75 cm² culture flasks as adherent monolayer cultures in Minimum Essential Medium (MEM) supplemented with 10% heat-inactivated fetal calf serum, 1 mM sodium pyruvate, 4 mM l-glutamine and 1% non-essential amino acids (from 100× ready-to-use stock). NIH/3T3 cells were maintained in Dulbecco’s Modified Eagle’s Medium (DMEM) supplemented with 10% of bovine calf serum. Cultures were maintained at 37 °C under a humidified atmosphere containing 95% air and 5% CO₂.

Cytotoxic effects of the test compounds were determined by means of a colorimetric microculture assay [MTT assay; MTT = 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2-H-tetrazolium bromide]. Cisplatin (Teva) was used as a positive control. Cells were harvested from culture flasks by trypsinization and seeded by using a pipetting system (Biotek Precision XS Microplate Sample Processor) at densities of 3 × 10⁴ (A549), 1 × 10⁵ (CH1) and 2 × 10⁵ (SW480) in 100 μL per well aliquots in 96-well microculture plates. For 24 h, cells were allowed to settle and resume proliferation. Test compounds were then dissolved in DMSO, diluted in complete culture medium and added to the plates where the final DMSO content did not exceed 0.5%. After 96 h of drug exposure, the medium was replaced with 100 μL per well of a 1 : 7 MTT/RPMI 1640 mixture [MTT solution, 5 mg mL⁻¹ of MTT reagent in phosphate-buffered saline; RPMI 1640 medium, supplemented with 10% heat-inactivated fetal bovine serum and 4 mM l-glutamine], and plates were incubated at 37 °C for a further 4 h. Subsequently, the solution was removed from all wells, and the formazan crystals formed by viable cells were dissolved in 150 μL of DMSO per well. Optical densities at 550 nm were measured with a microplate reader (Biotek ELx808) by using a reference wavelength of 690 nm to correct for unspecified absorption. The quantity of viable cells was expressed relative to untreated controls, and

programs and computer were used: structure solution, SHELXS-97; refinement, SHELXL-97; molecular diagrams, ORTEP-3; computer, Intel Core Duo. CCDC 1471829–1471831 and 1492553.

One-dimensional ¹H and ¹³C NMR and two-dimensional ³H–¹H COSY and ¹H–¹³C HMBC NMR spectra were recorded on two Bruker Avance III spectrometers at 500.32 or 500.10 MHz, respectively, at room temperature, and using standard pulse programs. ¹H and ¹³C shifts are quoted relative to the solvent residual signals. Electrosporation ionisation mass spectrometry (ESI-MS) was carried out with a Bruker Esquire 3000 instrument and the samples were dissolved in methanol. Elemental analyses were performed at the Microanalytical Laboratory of the University of Vienna with a Perkin Elmer 2400 CHN Elemental Analyzer (Perkin Elmer, Waltham, MA). IR spectra were recorded on a Bruker Vertex 70 Fourier transform IR spectrometer by using the ATR technique. UV-vis absorption spectra were recorded on a JASCO V670 spectrophotometer, while CD spectra were recorded on a JASCO J1500 spectrometer. The spectra were recorded at room temperature in a cuvette with 10 mm path length.
50% inhibitory concentrations (IC\textsubscript{50}) were calculated from concentration–effect curves by interpolation. Evaluation is based on the means from three independent experiments. A slightly modified procedure was used to test the antiproliferative effect in NIH/3T3 murine embryonal fibroblast cells, which is provided in the ESI.†

Mechanisms of cell death: assay for apoptosis induction

The assay was carried out using an Annexin V-FITC Apoptosis Detection Kit (Cat. No. PF 032) from Calbiochem according to the manufacturer’s instructions. The concentration of the A549 cell suspension was adjusted to approximately 0.5 × 10\textsuperscript{6} cells per mL in MEM and the cell suspension was distributed in 1 mL aliquots into a 24-well plate, and then incubated overnight at 37 °C and 5% CO\textsubscript{2}. The next day, the medium was removed and replaced by 1 mL MEM containing the compounds except the control samples. A549 cells were incubated in the presence of the compounds at 20 μM in the 24-well plate at 37 °C for 3 h, and 12H-benzo[a]phenothiazine (M627)\textsuperscript{28} and cisplatin (Teva) at 20 μM were used as positive controls. After the incubation period the samples were washed with PBS and fresh MEM medium was added to the samples. The cells were incubated overnight at 37 °C and 5% CO\textsubscript{2}. The next day, 200 μL 0.25% Trypsin (Trypsin-Versen) was added to the samples until cells appeared detached followed by the addition of 400 μL of MEM supplemented with 10% bovine serum. The cells were collected in Eppendorf tubes and centrifuged at 2000g for 2 min. The harvested cells were resuspended in fresh serum free MEM culture medium. After this step, the apoptosis assay was carried out according to the rapid protocol of the kit. The fluorescence was analysed immediately using a ParTec CyFlow flow cytometer (Partec GmbH, Münster, Germany).

Results and discussion

Synthesis and characterization of proligands and metal complexes

The chiral 2-hydroxy-3-methyl-[S]-pyrrolidine-2-carboxylylate-5-methylbenzaldehyde 4-N-pyrrolidine-3-thiosemicarbazone was prepared in three steps as described recently for the unsubstituted at the terminal nitrogen atom of the thiosemicarbazide moiety derivative.\textsuperscript{19} First, 3-chloromethyl-2-hydroxy-5-methylbenzaldehyde\textsuperscript{21} was allowed to react with L-proline methyl ester hydrochloride in the presence of triethylamine with the formation of the desired conjugate. Condensation reaction of this latter compound with 4-N-pyrrolidine-3-thiosemicarbazide\textsuperscript{16} followed by hydrolysis of the methyl ester group afforded the corresponding TSC coupled via a methylene group to L-Pro moiety (H\textsubscript{2}L\textsubscript{1}). The formation of desired species has been confirmed by \textsuperscript{1}H and \textsuperscript{13}C NMR measurements, as well as by ESI mass spectrometry. The mass spectrum recorded in the positive ion mode showed peaks at m/z 391 due to [M + H]\textsuperscript{+} ions. Aqueous solution of H\textsubscript{2}L\textsubscript{1} at neutral pH is optically active. The racemate H\textsubscript{2}L\textsubscript{1} was obtained similarly by using the (R/S)-β3-homoproline methyl ester instead of the L-proline methyl ester hydrochloride. The latter was prepared via a four-step procedure by exploring the Arndt–Eistert reaction as a common method of homologisation of an α-amino acid into β-amino acid (e.g., proline to β\textsuperscript{3}-homoproline) as shown in Scheme S1.† Briefly, in the first step the secondary amine in L-proline was protected by reaction with benzyl chloroformate in aqueous KOH solution. Then the N-protected L-proline was converted into the acyl halide by treating with excess oxalyl chloride in dichloromethane followed by methylation with (trimethylsilyl)diazomethane and formation of the α-diazoylketone. This latter conversion, known as Wolff rearrangement, is the key step involving the insertion of a CH\textsubscript{2} group.\textsuperscript{29} The α-diazoylketone was further rearranged in dry methanol in the presence of silver benzoate and triethylamine. Finally the amino group was deprotected with H\textsubscript{2} in the presence of 10% PdC in dry methanol. The synthesis can be performed on a large scale with 51% overall yield of β3-homoproline methyl ester. The reaction of β3-homoproline methyl ester with 3-chloromethyl-2-hydroxy-5-methylbenzaldehyde in THF/CH\textsubscript{3}Cl\textsubscript{2} afforded [1-(4-formyl-2-hydroxy-5-methylbenzyl)-(R/S)-pyrrolidin-2-yl]acetic acid methyl ester, which was purified by column chromatography to give an orange oil in 80% yield. Condensation of this product with 4-N-pyrrolidine-3-thiosemicarbazide accompanied by hydrolysis of the ester group resulted in H\textsubscript{2}L\textsubscript{2} in 43% yield. The formation of the desired ligand precursor was confirmed by ESI mass spectrometry, which showed the presence of a peak with m/z 405, attributed to [M + H]\textsuperscript{+} ions, as well as by \textsuperscript{1}H and \textsuperscript{13}C NMR spectroscopy.

By reaction of H\textsubscript{2}L\textsubscript{1} with NiCl\textsubscript{2}-6H\textsubscript{2}O in ethanol at room temperature the red complex [Ni(H\textsubscript{2}L\textsubscript{1})Cl]Cl·3H\textsubscript{2}O was synthesised in 82% yield. Similarly, starting from PdCl\textsubscript{2} and CuCl\textsubscript{2}-2H\textsubscript{2}O the complexes [Pd(H\textsubscript{2}L\textsubscript{1})Cl]Cl·H\textsubscript{2}O and [Cu(H\textsubscript{2}L\textsubscript{1})Cl]Cl·0.7H\textsubscript{2}O were isolated in 47 and 59% yields, respectively. ESI mass spectra recorded in the positive ion mode exhibit a strong peak at m/z 447.26 and m/z 452, which can be assigned to [Ni(H\textsubscript{1}L\textsubscript{1})]\textsuperscript{+} and [Pd(H\textsubscript{1}L\textsubscript{1})]\textsuperscript{+}, respectively, while the negative ion mass spectrum of 2 contains a strong signal at m/z 530.93 due to [Pd(L\textsubscript{1})Cl]\textsuperscript{-}. By reaction of a methanolic solution of CuCl\textsubscript{2}-2H\textsubscript{2}O with H\textsubscript{2}L\textsubscript{2} the complex [Cu(H\textsubscript{2}L\textsubscript{2})Cl\textsubscript{2}]H\textsubscript{2}O was obtained in 55% yield. ESI mass spectra recorded in the positive ion mode, showed the presence of a strong peak at m/z 466.31 attributed to [Cu\textsuperscript{11}(HL\textsubscript{2})]\textsuperscript{+}, while in the negative ion mode, peaks at m/z 464.10 and 500.05 due to [Cu\textsuperscript{11}(HL\textsubscript{2})]\textsuperscript{-} and [Cu\textsuperscript{11}(L\textsubscript{2})Cl]\textsuperscript{-}, respectively, were observed, in agreement with the X-ray diffraction structure (vide infra).

X-ray crystallography

Fig. 1 shows the structure of the chiral ligand precursor H\textsubscript{4}L\textsubscript{1} with selected bond distances and angles quoted in the legend. The compound crystallizes in the monoclinic space group C2 with two crystallographically independent molecules in the asymmetric unit. The conformation adopted by H\textsubscript{4}L\textsubscript{1} is very close to that of the ligand in complexes 1 and 2 (vide infra). The proline moiety is in the zwitterionic form, which makes the atom N\textsubscript{4a} in addition to C\textsubscript{14a} chiral. A strong intramolecular hydrogen bonding O\textsubscript{1a}···H···N\textsubscript{1a} with an O\textsubscript{1a}···N\textsubscript{1a}}
of 2.595(4) Å and an O1a–H⋯N1a of 143.4° is evident in the structure of H\textsubscript{2}L\textsubscript{1}. The atoms N2a and N4a act as proton donors to O3a\(^{\text{\textprime}}\)(−x + 1, y, −z + 1) and O2b\(^{\text{\textprime}}\)(−x + 1, y, −z + 1), respectively, forming hydrogen bonds N2a–H⋯O3a\(^{\text{\textprime}}\) and N4a–H⋯O2b\(^{\text{\textprime}}\) with an N2a⋯O3a\(^{\text{\textprime}}\) of 2.736(5) Å, an N2a⋯O3a\(^{\text{\textprime}}\) of 155.5° and an N4a⋯O2b\(^{\text{\textprime}}\) of 2.857(5) Å, an N2a⋯O3a\(^{\text{\textprime}}\) of 136.7°.

The results of X-ray diffraction studies of 1, 2 and 4 are shown in Fig. 2 and 3. Compounds 1 and 2 are isoostructural and crystallised in the noncentrosymmetric monoclinic space group P2\(_1\), as pure enantiomers, as also confirmed by the Flack parameter quoted in Table 1, with two chiral atoms of the same configuration (vide infra). Complex 4 crystallised in the centrosymmetric monoclinic space group C2/c. The asymmetric unit in 1 and 2 consists of two crystallographically independent cations [M(H\textsubscript{2}L\textsubscript{1})Cl\textsubscript{2}]\(^+\) (M = Ni, Pd) and two chloride counterions, where H\textsubscript{2}L\textsubscript{1} is the charge-neutral proline–thiosemicarbazone hybrid, while that of 4 consists of one complex, [Cu(H\textsubscript{2}L\textsubscript{2})Cl\textsubscript{2}]. The ligands H\textsubscript{2}L\textsubscript{1} in 1 and 2 and H\textsubscript{2}L\textsubscript{2} in 4 act as a tridentate binding to the metal(II) via the phenolate oxygen atom O1, the nitrogen atom N1 and the thione sulfur S1 as shown in Fig. 2 and 3 for one of the two crystallographically independent cations [Ni(H\textsubscript{2}L\textsubscript{1})Cl\textsubscript{2}]\(^+\), [Pd(H\textsubscript{2}L\textsubscript{1})Cl\textsubscript{2}]\(^+\) and the complex [Cu(H\textsubscript{2}L\textsubscript{2})Cl\textsubscript{2}]. The ligands are deprotonated at O1, but protonated at N4, so that the overall protonation level does not change. Protonation at N4 makes this atom chiral (S configuration) in 1 and 2. The second chiral centre C14 has the same S configuration. According to the literature, the nitrogen atom of the L-proline ligand or moiety upon coordination to metal ions or protonation in most cases adopts the same configuration as the asymmetric carbon atom,\(^{30}\) although cases where the two atoms adopt opposite configurations are also known.\(^{31}\) The coordination geometry of nickel(II) and palladium(II) is square-planar. The fourth coordination place is occupied by a chlorido ligand.

The overall positive charge of the complex cation is counterbalanced by another chloride ion.

The Pd–O, Pd–N, Pd–Cl and Pd–S bond lengths in 2 are well-comparable to those found in the complex [Pd(HSal\textsubscript{4}Et)Cl]\(\cdot\)H\textsubscript{2}O, where HSal\textsubscript{4}Et = 2-hydroxybenzaldehyde 4-N-ethylothiosemicarbazone, at 2.019(2), 1.965(2), 2.3078(8) and 2.2456(9) Å, respectively.\(^{22}\) The protonated atom N4 in cation A acts as a proton donor in bifurcated hydrogen bonding interaction to O2a and Cl\(_2\)(x − 1, y, z − 1), while N4b in cation B acts as a proton donor to O1B and O2B as shown in Fig. S1.\(^{†}\) In addition, strong hydrogen bonding interactions N2a–H⋯Cl\(_2\) [N2a⋯Cl\(_2\) 3.157(6) Å, N2a⋯Cl\(_2\) 160.2°], N2b–H⋯Cl\(_2\)\(^{\text{\textprime}}\)(−x + 1, y − 0.5, −z + 1) [N2b⋯Cl\(_2\)\(^{\text{\textprime}}\) 3.162(0) Å, N2b⋯Cl\(_2\)\(^{\text{\textprime}}\) 156.5°] and O3b⋯H⋯Cl\(_2\)\(^{\text{\textprime}}\)(−x + 1, y + 0.5, −z + 1) [O3b⋯Cl\(_2\)\(^{\text{\textprime}}\) 2.926(0) Å, O3b⋯Cl\(_2\)\(^{\text{\textprime}}\) 170.4°] are evident in the crystal structure of 2. Closely similar hydrogen bonding interactions for 1 are quoted in Table S1.\(^{†}\)

A feature of note is the presence of short intermolecular contacts Ni⋯S and Pd⋯S between neighbouring complex cations of ca. 3.69–3.70 and 3.59–3.60 Å, respectively, as shown in Fig. S2 and S3.\(^{†}\) The interplanar separation between the aromatic rings of the interacting species is ca. 3.25 and 3.16 Å, in 1 and 2, respectively. Formation of short contacts of this type is not characteristic of the complex [Pd(HSal\textsubscript{4}Et)Cl]\(\cdot\)H\textsubscript{2}O mentioned previously.

The coordination polyhedron of copper(II) in 4 is described as a square-pyramid (r = 0.15).\(^{33}\) The tridentate ligand H\textsubscript{2}L\textsubscript{2} and one chloride occupy the basal plane, while the second chlorido ligand occupies the apical position. Comparison of the bond lengths Cu–Cl1 and Cu–Cl2 (see the legend to Fig. 3) indicates markedly weaker binding of the apical chlorido ligand to copper(II). The protonated atom N4 acts as a proton donor in intramolecular bifurcated hydrogen bonding interaction to O1 and Cl2 [N4⋯O1 2.624(10) Å, N4⋯O1 132.5°; N4⋯Cl1 3.684(8) Å, N4⋯Cl1 149.0°]. In addition, strong intramolecular hydrogen bonding interactions N2–H⋯Cl\(_{2}^{\text{\textprime}}\)(−x + 1, −y + 1, −z) [N2⋯Cl\(_{2}^{\text{\textprime}}\) 3.197(8) Å, N2–H⋯Cl\(_{2}^{\text{\textprime}}\) 156.6°] and O3⋯H⋯Cl\(_{2}^{\text{\textprime}}\)(x, −y + 1, z + 0.5) [O3⋯Cl\(_{2}^{\text{\textprime}}\) 2.925(7) Å, O3⋯H⋯Cl\(_{2}^{\text{\textprime}}\) 167.5°] are evident in the crystal structure of 4.

NMR spectroscopy

The \(^1\)H NMR spectra of 2 and H\textsubscript{2}L\textsubscript{1} have been analysed. The 2D homonuclear COSY \(^1\)H–\(^1\)H and heteronuclear HMBC \(^1\)H–\(^13\)C correlations were applied to assign the NMR signals (see Fig. S4†). The NMR spectra of H\textsubscript{2}L\textsubscript{1} are consistent with the X-ray diffraction structure. We note here the particular splitting of protons of the methylene group which connects the aromatic and proline rings. The two protons C\(_6\)H\(_3\) and C\(_8\)H\(_3\) are magnetically inequivalent due to their different spatial orientation with respect to the bond C\(_6\)H\(_3\)–N\(^4\)C\(_9\)O\(_3\). The simu...
The analysis of the $^1$H NMR spectra (Fig. 4) resulted in the geminal $^2J_{\text{C8a}-\text{C8b}}$ constant of 13 Hz and chemical shifts $\delta_{\text{C8a}} = 4.177$ and $\delta_{\text{C8b}} = 4.005$ ppm. The proton in the $\alpha$ position ($\delta_{\text{C9H}} = 3.554$ ppm) of the proline ring is split due to its vicinal proton-proton interaction with the two protons $\text{C}^{10}\text{H}_2$. 
The approximate dihedral angle for the conformation adopted in this case (Fig. 4, right) can be calculated by using the Karplus equation:34,35

\[
\gamma = \begin{cases} 
8.5 \cos^2 \phi - 0.28 & 0^\circ \leq \phi \leq 90^\circ \\
9.5 \cos^2 \phi - 0.28 & 90^\circ \leq \phi \leq 180^\circ 
\end{cases}
\]

The conformation of the proline ring in H3L1 is consistent with previously reported data.36,37

As can be seen from Fig. 3, the C8H2 group in 2 has a different splitting pattern and chemical shift in comparison with H3L1. A similar change in chemical shift is observed for C8H. The downfield shift of proton resonances of the proline ring in 2 can be related to double protonation of the proline group (amine nitrogen and carboxylato groups) in the complex in comparison with single protonation in the zwitterionic form of the ligand precursor. The single crystal X-ray analysis shows that the proline nitrogen (N4) is protonated in both forms of the ligand precursor. The single crystal X-ray analysis in comparison with single protonation in the zwitterionic form shows that the proline nitrogen (N4) is protonated in both H3L1 and in 2. In 2 an additional protonation of the ligand at O3a was also proved by X-ray analysis. The protonation state of N4 is also preserved in solution (DMSO), in accord with the additional splitting of two protons of the C8H2 group. The modification in the splitting pattern of C8H signals can be associated with the change in spatial orientation of the C8H2 group after coordination. According to the simulation of the NMR spectra the best fit between theoretical and experimental spectra indicates the same magnitude of vicinal coupling constant between the protons C8H and HN4 and C8H and HN4 and corresponds to the dihedral angle of 40° (JCHH-CH = 5.0 Hz) (Fig. 3). This value corresponds to an average conformational position upon rotation around the C8H–N2C2 single bond on the time scale of NMR spectroscopy. The protonation also affects the splitting of the α proton (C8H), and all 1H NMR resonances are upfield shifted (δCH = 4.419, δCH = 4.307 and δCH = 4.509 ppm). The HN4 signal appears in the 1H NMR spectra at 9.97 ppm as a broad signal (13.0 Hz) as a consequence of splitting and chemical exchange in solution. The correlations between HN4 and C8H and C8H were confirmed by the presence of cross peaks in COSY 1H spectra (Fig. S5†). The geminal JHH, constant is of the same magnitude of 13.0 Hz.

Dissolution of the red solid of 1 in methanol resulted in the formation of a green solution suggesting a change in coordination geometry of nickel(n). The 1H NMR spectrum of 1 showed broad lines, which indicated the presence of paramagnetic species in solution. We determined the effective magnetic moment of 1 in CD3OD (1.58 × 10−2 M) at 298 K by using the NMR method of Evans.38 The value amounts to 3.26 B.M., which is typical for octahedral nickel(n) complexes with d8 electronic configuration.39 The CD spectrum of a methanolic solution of 1 (Fig. 4, green trace) indicates the presence of asymmetric centres in the molecule. The CD signals are correlated to the absorption bands for the ligand precursor and show the absence of CD signals in the visible region. The absence of CD signals in the visible region of the spectrum indicates that the proline moiety with its two asymmetric centres is not bound to the nickel(n) in solution.

The electronic absorption spectrum of 1 in methanol in the visible and NIR regions shows three bands with a λmax of 865 (11 560 cm−1), 770 (12 987 cm−1) and 620 (16 129 cm−1) nm (Fig. 5) which can be attributed to $^3A_2g \rightarrow ^3T_2g(F), ^3A_2g \rightarrow ^1E_g(D)$ and $^3A_2g \rightarrow ^3T_1g(F)$ transitions of Ni(n) in an octahedral environment, respectively.40 Spin-allowed transitions are known to give broad absorption bands, while spin-forbidden transitions are usually sharp.41 For nickel(n) (d8) in an octahedral environment $^3A_2g$ is the ground term and the spin allowed transition $^3A_2g \rightarrow ^3T_2g(F)$ is equal to the value of the crystal field splitting (10 Dq).42 The value (11 560 cm−1) is consistent with those reported for octahedral nickel(n) complexes.43 The third characteristic transition $^3A_2g \rightarrow ^3T_1g(P)$ is expected in the range of 19 000–27 000 cm−1, which is obscured by strong intraligand absorption bands.

Stability in aqueous solution

Quite recently we reported on complex formation reactions of copper(n) with l-Pro-STSC in 30% (w/w) DMSO/H2O.19 Several determined thermodynamic cumulative stability constants (log β([CuL]) = 21.58(3), log β([CuL]) = 17.54(3) and log β([CuL]) = 6.97(4)) along with the computed pM (= −log [M]) value of 13.4 (pH 7.4, cCu = 1 μM; cL/cCu = 10) undoubtedly indicate significantly high stability of copper(n) complexes, which are closely related to those studied in this work (3 and 4). In addition, we monitored the behaviour of 4 in aqueous solution with 1% DMSO by UV-vis spectroscopy. The data (Fig. S6 and S7†) indicate that the complex remains intact over 24 h in solution.
Cytotoxicity and the mechanism of cell death

The antiproliferative activity of the two organic hybrids H₂L¹ and H₂L² and the four metal complexes 1–4 was investigated in the human cancer cell lines A549 (nonsmall cell lung carcinoma), CH1 (ovarian carcinoma) and SW480 (colon carcinoma) by means of the colorimetric MTT assay. Generally, CH1 cells are more sensitive to the compounds investigated in this work, giving up to 5 times lower IC₅₀ values than SW480 cells, while A549 cells are less sensitive, giving up to 9 times higher IC₅₀ values than SW480 cells. The ligand precursors H₂L¹ and H₂L² and complexes 1–4 show different cytotoxic potencies, with IC₅₀ values ranging from 0.9 to 308 μM (Table 2). The following structure–activity relationships are of note: (i) impact of metal coordination as compared to the ligand precursors; (ii) negligible role of square-planar coordination geometry of metal complexes in the underlying mechanism of their cytotoxicity; (iii) the impact of substitution at the terminal nitrogen atom of the thiosemicarbazide moiety and (iv) the effect of increasing the structural flexibility of the amino acid moiety by the insertion of a methylene group and (iv) the elimination geometry of metal complexes in the underlying mechanism of their cytotoxicity; (vii) impact of metal coordination as compared to the ligand precursors; (ii) negligible role of square-planar coordination geometry of metal complexes in the underlying mechanism of their cytotoxicity; (iii) the impact of substitution at the terminal nitrogen atom of the thiosemicarbazide moiety and (iv) the effect of increasing the structural flexibility of the amino acid moiety by the insertion of a methylene group between the pyrrolidine ring and the carboxylic group (proline amino acid moiety by the insertion of a methylene group and (iv) the elimination geometry of metal complexes in the underlying mechanism of their cytotoxicity; (vii) impact of metal coordination as compared to the ligand precursors; (ii) negligible role of square-planar coordination geometry of metal complexes in the underlying mechanism of their cytotoxicity; (iii) the impact of substitution at the terminal nitrogen atom of the thiosemicarbazide moiety and (iv) the effect of increasing the structural flexibility of the amino acid moiety by the insertion of a methylene group between the pyrrolidine ring and the carboxylic group (proline amino acid moiety by the insertion of a methylene group and (iv) the elimination geometry of metal complexes in the underlying mechanism of their cytotoxicity.

In Table 2, IC₅₀ values for the cancer cells. The antiproliferative activity in all three cell lines, in line with other reported data. The IC₅₀ values of the nickel(II) complex related to 3, we can conclude that the role of coordination geometry in the underlying mechanism of cytotoxicity seems to be marginal, if any, when we compare the IC₅₀ values of 1–3 with those of H₂L¹. This conclusion remains valid if we exclude 1 from the series due to the change in coordination geometry in solution to octahedral. Substitution at the terminal nitrogen atom of the thiosemicarbazide moiety, namely pyrrolidine vs. NH₂, has a marked effect on cytotoxicity as well, which can be compared with that of metal coordination. A 23- (CH1) and more than 10-fold (SW480) decrease of IC₅₀ values is achieved via this substitution for metal-free compounds, and a 5- to 5.5-fold decrease is achieved for the same structural modification in copper(II) complexes. Insertion of a CH₂ group between the pyrrolidine ring and the COOH group of the amino acid moiety reduces markedly the antiproliferative activity of both the ligand precursor and its copper(II) complex. Based on IC₅₀ values a maximal 8-fold drop in cytotoxicity was observed on going from 3 to 4. The antiproliferative activity of complex 3 is slightly lower, but comparable to the clinical drug cisplatin. Compounds found to be active (H₂L¹, H₂L², complexes 3 and 4) in human cancer cells were tested for their antiproliferative activity in the noncancerous murine embryonal fibroblast (NIH/3T3) cell line as well. They showed no selectivity as their IC₅₀ values for the normal cells are comparable to those obtained for the cancer cells.

The mechanism of cytotoxicity induced by H₂L¹, H₂L² and complexes 3 and 4 was assessed by analysis of A549 cells stained with Annexin-V and propidium iodide (PI) using flow cytometry. Compounds M627 and cisplatin were used as positive controls. Apoptosis is a fundamental mode of cell death which performs a regulatory function during normal development, in tissue homeostasis, and in some disease processes. In normal viable cells phosphatidylserine (PS) is located on the cytoplasmic surface of the cell membrane. Upon induction of apoptosis, rapid alterations in the organisation of phospholipids in most cell types occur, leading to exposure of PS on the cell surface. In this assay a fluorescein isothiocyanate (FITC) conjugate of Annexin-V (a Ca-dependent phospholipid-binding protein with a high affinity for PS) was used, allowing detection of apoptosis. Since membrane permeabilisation is observed in necrosis, necrotic cells will also bind Annexin-V-FITC. PI is used to distinguish between viable, early apoptotic and necrotic or late apoptotic cells. Necrotic cells bind Annexin-V-FITC and stain with PI, while PI is excluded from viable (FITC negative) and early apoptotic (FITC positive) cells. In the absence of phagocytosis the final stages of apoptosis involve necrotic-like disintegration of the total cell; thus cells in late apoptosis will be labeled with both FITC and PI. The fluorescence of PI (FL3) is plotted versus Annexin-V fluorescence (FL1) as shown in Fig. 6 for the positive controls and complex 4. The early apoptotic cells in percentage were compared for the tested compounds (Fig. S8†). Elevated early apoptosis was observed for one of the studied ligand precursors (H₂L²) and complexes 3 and 4 as well as for cisplatin and M627 compared with the DMSO control. According to these

³ Applied protocol described in the ESI. ² Taken from ref. 44. ¹ Taken from ref. 45. ⁴ Not determined.
High H2L1, 24.7% and decreases in all three cell lines in the following rank order: H2L1: 51.9%, H2L2: 68.7% vs. complex 3: 24.7% and 4: 30.1% at the applied concentration (20 µM).

Conclusions

Two homologous L-proline- and β3-homoproline-thiosemicarbazone conjugates H2L1 and H2L2 were synthesised via multistep procedures. Substitution of the terminal amino group by pyrrolidine should presumably increase the lipophilicity, while insertion of one CH2 group between the pyrrolidine moiety and the COOH group of the amino acid enhanced the structural flexibility of the potential ligand. Both ligands were found to form square-planar and square-pyramidal complexes [Ni(H2L1)Cl]Cl·1.3H2O (1:1-1.3H2O), [Pd(H2L1)Cl2]Cl·H2O (2·H2O), [Cu(H2L1)Cl]Cl·0.7H2O (3:0.7H2O) and [Cu(H2L2)Cl]2·H2O (4·H2O), by reactions of the ligand precursors with the corresponding metal salts in ethanol or methanol. The two homologous ligand precursors and four metal complexes proved to be suitable for performing antiproliferative activity assays and to establish the notable and clear-cut structure–cytotoxicity relationships for three human cancer cell lines (A549, CH1 and SW480). The metal ions exert marked effects in a divergent manner: copper(II) modulates the cytotoxic potency of H2L1 and H2L2 in a beneficial way, whereas coordination to nickel(II) and palladium(II) impairs the antiproliferative activity of H2L1. The cytotoxicity of H2L1 and metal complexes 1–3 decreases in all three cell lines in the following rank order: 3 > H2L1 > 1 > 2. Complex 3 exhibits the highest biological activity in all three cell lines with IC50 values of 2.4, 0.9 and 1.0 µM in A549, CH1 and SW480 cells, respectively. On the other hand, compounds H2L1 and H2L2 and complexes 3 and 4 do not display selectivity to cancerous cell lines over normal cells. The flow cytometry analysis of A549 cells doubly stained with Annexin-V/PI showed induced early apoptosis in the case of H2L2 and complexes 3 and 4. The role of the square-planar geometry in 1–3 (or more strictly in 2 and 3) in the underlying mechanism of cytotoxicity seems to be negligible, while structural modifications at the terminal amino group of thiosemicarbazide and amino acid moieties have a significant impact on the antiproliferative activity of both ligand precursors and copper(II) complexes. Substitution of the terminal NH2 group of the thiosemicarbazide moiety by a pyrrolidinyl one resulted in a 23- (in CH1 cells) and >10-fold enhancement of cytotoxicity of metal-free compounds, and a 5- to 5.5-fold increase for the corresponding copper(II) complexes. In contrast, homologisation via insertion of a CH2 group between the pyrrolidine ring and the carboxylate moiety of the amino acid reduced markedly the cytotoxicity of the ligand and its copper(II) complex. The SARs found will be explored further for the development of effective anticancer agents in the reported series of thiosemicarbazone–proline hybrids.
