Synthesis of radioiodinated probes to evaluate the biodistribution of a potent TRPC3 inhibitor†‡

Masayori Hagimori, a Takahiro Murakami, a Kinue Shimizu, b Motohiro Nishida, bc Takashi Ohshima^b and Takahiro Mukai*a

The transient receptor potential canonical 3 (TRPC3) channel is a member of the TRPC family that contributes to the entry of Ca²⁺ through the plasma membrane or modulates the driving force for Ca²⁺ entry channels. The pyrazole compound Pyr3 has recently been reported to be a selective TRPC3 inhibitor and has become an attractive research tool and therapeutic agent for the treatment of heart failure. However, the in vivo characteristics of Pyr3 have not been investigated. To monitor the fate of Pyr3 in vivo, we designed and synthesized a radioiodinated Pyr3 probe ([125]]I-Pyr3) by introducing radioiodine at the 2-position of the central phenyl ring of Pyr3. I-Pyr3 was shown to have direct TRPC3 inhibition activity similar to that of Pyr3 in TRPC3-overexpressing HEK293 cells. Using the tributyltin derivative as a radioiodination precursor, [1251]I-Pyr3 was successfully prepared with high radiochemical purity. Biodistribution studies of [1251] I-Pyr3 and [1251]I-Pyr8 (the esterolysis product of [1251]I-Pyr3) indicated high uptake of intact [1251]I-Pyr3 in the lung and rapid metabolism to [125]]I-Pyr8. These findings provide useful information about the in vivo kinetics of the selective TRPC inhibitor Pyr3.

1 Introduction

Changes in the intracellular concentration of the calcium ion ([Ca²⁺]_i) modulate a wide range of cellular processes, including secretion, gene expression, proliferation, and cell death. 1-4 Although [Ca²⁺]; is normally maintained in the 10-100 nM range, it is increased by the release of Ca²⁺ from intracellular stores and the endoplasmic reticulum (ER) on activation. In addition, [Ca²⁺]_i is increased by the influx of Ca²⁺ across the plasma membrane in response to extracellular stimulation.⁵ Abnormal changes in [Ca²⁺]_i influence intracellular Ca²⁺ homeostasis and can cause diseases.⁵

The transient receptor potential canonical (TRPC) channel is a subfamily of TRP channels and contributes to changes in [Ca²⁺]_i by serving as a Ca²⁺ entry pathway in the plasma membrane or by modulating the driving force for Ca2+ entry chan-

nels.6 It has been reported that TPRC channels are closely related to heart diseases, including cardiac hypertrophy and fibrosis, and cancer.7-10 TRPC channels can be divided into seven isoforms (TRPC1-TRPC7), and TRPC1 and TRPC3-7 are broadly expressed in mammals. 11,12 TRPC channels are activated in response to membrane receptors linked to phospholipase C (PLC), including PLCβ and PLCγ. TRPC3, TRPC6, and TRPC7 are directly activated by PLC-derived diacvlglvcerol (DAG).6

To elucidate the functions of a TRPC channel, several small molecules, such as SKF 96365, LOE908, and 2-APB, have been evaluated as TRP inhibitors. 13,14 However, the roles played by the TRPC channels have not been adequately characterized because these inhibitors exhibit low selectivity toward TRPC channels. BTP2 has been reported to be a TRPC channel inhibitor that does not influence mitochondrial Ca2+ signaling, ER Ca²⁺ release, or K⁺ channels in T-cells. However, BTP2 lacks TRPC subtype selectivity. 15-17 The pyrazole compound Pyr3 has been recently reported to be a selective TRPC3 inhibitor that directly inhibits the TRPC3 channel by binding to its extracellular side. 18 Pyr3 regulated the TRPC3-mediated Ca²⁺ influx in B lymphocytes and eliminated the B cell receptor-induced Ca2+ oscillation. Pyr3 also inhibited pressure overload-induced cardiac hypertrophy in mice with transverse aortic constriction.18 Furthermore, in an in vitro model of stent-induced arterial injury, Pyr3 prevented arterial injury by suppressing agonist-induced Ca2+ entry into vascular smooth muscles.19

Research Article MedChemComm

These findings suggest that Pyr3 could be used as a research tool and a therapeutic agent for the treatment of heart failure. Nevertheless, little is known about the in vivo characteristics of Pvr3, including its distribution, metabolism, and elimination. In addition, because the ester moiety of Pyr3 is easily hydrolyzed, Pyr3 is converted to Pyr8, the carboxylic acid derivative, which shows little TRPC3 inhibition. Radiolabeled probes are widely used to study the in vivo characteristics of drugs. Iodine radioisotopes (123I, 125I, and 131I) have higher specific activities than β-emitters, such as ³H or ¹⁴C, and are commonly used in biological assay and in vivo imaging. 125I has a relatively long half-life and emits low energy photons, thus the pyrazole compounds were labeled with ¹²⁵I. In this study, we synthesized the radiolabeled probes ([125]]I-Pyr3 and [125]I-Pyr8) (Fig. 1) and used them to monitor the fate of Pyr3 in vivo.

2 Results and discussion

2.1 Chemistry

Pyr3 comprises two structural ethyl-3motifs: group trifluoromethylpyrazole-4-carboxylate and trichloroacrylic amide group. The trichloroacrylic amide group of Pyr3 is critical for the observed TRPC3-selective inhibition. 18 The effect of introducing a functional group to the central phenyl ring of Pyr3 on TRPC3 channel inhibition or selectivity has not been reported. We designed ethyl 1-(2-[125]]iodo-4-(2,3,3-trichloroacrylamido)phenyl)-5-(trifluoromethyl)-1H-pyrazole-4-carboxylate, [125]I-Pyr3, to introduce radioiodine at the 2-position of the central phenyl ring of Pyr3. Nonradioactive I-Pyr3 was synthesized via the route outlined in Scheme 1. Reaction of 2-bromo-1-fluoro-4nitrobenzene with hydrazine hydrate, followed by treatment with ethyl 2-(ethoxymethylene)-4,4,4-trifluoro-3-oxobutyrate, afforded the pyrazole derivative 3 in 94% yield. Treatment of 3 with zinc dust and aqueous NH₄Cl afforded the amine 4 in 95% yield. A bromo to tributyltin exchange reaction using Pd(PPh₃)₄ and a subsequent iododestannylation reaction yielded the iodine derivative 6. I-Pyr3 was prepared from 6 in 60% yield by treatment with 2,3,3-trichloroacryloyl chloride. Alkaline hydrolysis of the ester moiety of I-Pyr3 afforded the carboxylic acid derivative, I-Pyr8, in 18% yield.

2.2 Measurement of intracellular Ca²⁺ concentration

The ability of Pyr derivatives to inhibit TRPC3-mediated Ca²⁺ influx in vitro was evaluated using TRPC3-overexpressing

HEK293 cells (Fig. 2). I-Pyr3 showed potent inhibition of the TRPC3 channel-mediated Ca²⁺ influx that was only slightly poorer than that of the mother compound (Pvr3). 18 This result suggested that the introduction of iodine at the 2-position of the central phenyl ring of Pyr3 did not affect its ability to inhibit the TRPC3-mediated Ca2+ influx and that 125I-labeled I-Pvr3 could be a promising probe to monitor the fate of Pyr3 in plasma.

2.3 Radiosynthesis

The radioiodinated analog [125I]I-Pyr3 was obtained via the iododestannylation of tributyltin precursor 7, which was obtained from the reaction of amine 5 with 2,3,3-

trichloroacryloyl chloride. However, its radiochemical yield was only 15% when N-chlorosuccinimide was used as an oxidant. After the optimization of reaction conditions, the radiochemical yield of [125]I-Pvr3 improved to 39% when chloramine-T was used as an oxidant (Scheme 2). The carboxylate analog [125]I-Pyr8 was also obtained in high yield (84%) via the alkaline hydrolysis of the ester moiety of [125]I-Pyr3. The radiochemical purities and specific activities of these [125] I-labeled compounds were greater than 98% and greater than 26.3 GBq µmol⁻¹, respectively.

2.4 Stability studies

The in vitro stability of [125I]I-Pyr3 in 20 mM phosphate buffer (PB; pH 7.4) or mouse plasma at 37 °C was evaluated using radio-TLC analysis (Fig. 3). The radioactivity of [125I]I-Pyr3 remained >95% intact for 24 h in PB, while the radioactivity of [125]I-Pvr3 rapidly decreased and completely disappeared after 6 h in mouse plasma. The metabolite of [125I]I-Pyr3 was identified as [125I]I-Pyr8, indicating the rapid hydrolysis of the ester group of $[^{125}I]I$ -Pyr3.

2.5 In vivo biodistribution in normal mice

To characterize the in vivo kinetics of Pvr3, a biodistribution study of [125I]I-Pyr3 was carried out in normal ddY mice (Table 1). The radioactivity of [125] I-Pyr3 cleared rapidly from the blood pool and showed considerable accumulation in the lung, small intestine, and liver 10 min after injection. In addition, accumulation of radioactivity was broadly observed in the stomach, heart, kidney, and muscle. The thyroid accumulation was low, indicating high stability against in vivo deiodination. Because [125]I-Pyr3 was hydrolysed to [125]I-Pyr8, the distribution of radioactivity after administration of [125]I-Pyr3 might reflect the distribution of [125]I-Pyr8. Therefore, we performed a biodistribution study of [125I]I-Pyr8 (Table 2). Similar to [125I]I-Pyr3, [125I]I-Pyr8 showed rapid blood clearance and considerable accumulation of radioactivity in the small intestine and liver. However, the lung radioactivity after administration of [125]I-Pvr8 was dramatically lower compared to that after [125I]I-Pyr3 administration. These results indicated that [125]I-Pyr3 is broadly distributed, especially to the lung, as an intact form at early times post-injection, and that this is followed by rapid metabolism to [125] I-Pyr8.

3 Conclusions

We successfully designed and synthesized [125I]I-Pyr3 and [125I]I-Pyr8 and used these compounds for the *in vivo* characterization of the selective TRPC3 inhibitor Pyr3. The ability of I-Pyr3 to inhibit TRPC3-mediated Ca²⁺ influx was comparable to Pyr3. Biodistribution studies of [125I]I-Pyr3 and [125I]I-Pyr8 in normal mice showed that [125I]I-Pyr3 is highly distributed to the lung as an intact form at early times post-injection and that this is followed by rapid metabolism to [125I]I-Pyr8. These findings provide useful information about the *in vivo* kinetics of the selective TRPC inhibitor Pyr3.
