The synthesis of α -nitroxy-substituted oxime derivatives has been achieved by an unprecedented metal-assisted addition of a nitrate anion to bis(oxy)enamines, which are readily available from nitronates or nitroalkanes. The method has a broad scope and provides access to α -nitroxy-oximes and their cyclic ethers including nitroxy-substituted isoxazolines and dihydro-1,2-oxazines, which are of interest as potential NO-donors and intermediates in the synthesis of bioactive molecules.

Introduction

Nitrate esters are widely used in pharmaceuticals as efficient NO donors¹ with vasodilative,^{1a} vasorelaxant,^{1b} and anti-tumor activities.^{1c} Since NO is associated with the cytotoxic and anti-microbial functions of the immune system, the introduction of a nitroxy group in natural molecules and pharmaceuticals significantly enhances their efficacy.^{1d} This strategy is widely applied in the design of hybrid drugs.^{1d-h}

In organic synthesis, nitrates are considered convenient substrates for nucleophilic substitution reactions, due to the good leaving group ability of the ONO₂ fragment.² Nitrates are employed as intermediates in the synthesis of alcohols³ and aldehydes⁴ from the corresponding halides. Furthermore, nitrates of small alcohols are also well-known high-energy materials and components of explosive compositions.⁵

Traditional methods for the introduction of the ONO₂ fragment in organic molecules are based either on the direct nitration of alcohols⁶ or on the nucleophilic S_N1-type substitution of halides in haloalkanes, upon the action of silver or mercury nitrate.⁷ Another method substantially less explored

is nucleophilic addition of a nitrate anion to double carbon-carbon bonds.^{8,9} Such processes are usually realized under oxidative conditions (Scheme 1, eqn (1)),⁸ or initiated by the addition of an electrophile to a C=C bond, followed by the nucleophilic attack of a nitrate anion on the carbocation or onium ion (Scheme 1, eqn (2)).⁹ However, examples of direct addition of a nitrate anion to an activated carbon-carbon double bond as well as its participation in S_N' type substitution reactions are, to the best of our knowledge, unprecedented to date.

The carbon–carbon double bond in bis(oxy)enamines **1**, readily available by silylation of nitronates,¹⁰ is easily attacked by some nucleophiles, thus forming α -substituted oximes and their ethers as a result of a formal S_N' substitution of the silyloxy group.¹¹ We were interested in employing nitrate anions as nucleophiles in reactions with bis(oxy)enamines, in order to obtain α -nitroxy-oximes and their cyclic ethers (Scheme 1, eqn (3)). These products are virtually unknown in the literature,¹² though first attempts to synthesize simple α -nitroxy-oximes (so-called “nitrosates”) by nitration of some olefins with N_2O_4 date back to the 19th century in the studies of Guthrie,^{13a} Wallach^{13b} and Ipatiew.^{13c} However, in those times the structure of “nitrosates” could not be determined unambiguously.

Results and discussion

Recently, we have demonstrated that the reactions of bis(oxy)enamines with halide anions are promoted by Lewis acids, in particular transition metal and magnesium salts.¹⁴ Therefore, to achieve the desired transformation we studied the interactions of model cyclic bis(oxy)enamine **1a** with a series of

main and transition group metal nitrates (Table 1). In our experiments, crystal hydrates were usually used as they were the most readily available form of metal nitrates. The latter were dissolved in tetrahydrofuran (in the event of insolubility, dimethylformamide was used as a solvent instead) and treated with a solution of **1a** in dichloromethane.

As can be seen from the data in Table 1, almost all studied metal nitrates produced the target product **2a** with full conversion of enamine **1a**. An exception was lithium nitrate which gave low conversion of the starting material (Table 1, entry 1). The major by-products identified in experiments were 3-hydroxy-methyl-substituted 1,2-oxazine **3a**, its trimethylsilyl ether **4a**, as well as formate **5a** and 1,4-butanediol ether nitrate **6a**. Products **5a** and **6a** arise from competitive addition of solvent to bis(oxy)enamine **1a** (*vide infra*). In reactions with magnesium, aluminium and gallium nitrates, the desired nitro-ester **2a** was obtained in 42–59% yields (Table 1, entries 2–4). The reaction of bis(oxy)enamine **1a** with lead and bismuth nitrates (Table 1, entries 5 and 6) produced formate **5a** in addition to dihydrooxazines **2a**, **3a** and **4a**. In the case of bismuth nitrate, formate **5a** was obtained as the major product (35% yield). Nitrates of early transition metals afforded nitrate ester **2a** in

^a Yields of all products were determined by ¹H NMR with an internal standard. ^b Conversion – 27%. ^c By-products were not identified. ^d Conversion – 82%.

moderate to good yields, while by-product **3a** was usually formed in 10–30% yield (Table 1, entries 7–16). It should be noted that employing anhydrous nitrates allows for the suppression of the formation of **3a**, but does not lead to the increase of the yield of nitrate **2a** due to the formation of unidentified by-products (*cf.* entries 9 and 10 in Table 1).

The best result was achieved with chromium(III) nitrate nonahydrate, which gave product **2a** in 71% yield (Table 1, entry 14). Changing of solvent to dimethylformamide led to a decrease of nitrate **2a** yield (Table 1, entry 15).

Yttrium, lanthanum and europium nitrates produced 3-hydroxymethyl-substituted 1,2-oxazine **3a** as the major product, while the yield of target **2a** did not exceed 24% (Table 1, entries 17–19). The formation of nitrate ester **2a** was also observed in reactions of enamine **1a** with ammonium nitrate and nitric acid (yield of 35% and 58% respectively, entries 20 and 21 in Table 1). Our attempts to use other non-metal based Lewis acids such as boron trifluoride to promote the addition of nitrate to enamine **1a** were not successful and led to **3a** as the major product (entry 22 in Table 1).

Reaction with chromium nitrate was subsequently studied in more detail. UV-Vis titration of chromium nitrate solution in THF with bis(ox)enamine **1a** revealed that the majority of chromium is present in the form of the aqueous complex $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$ (see the ESI†). This implies that a catalytic process could be designed using a catalytic amount of $\text{Cr}(\text{NO}_3)_3$, in combination with a cheaper nitrate source. Indeed, addition of 10 mol% of chromium nitrate in the reaction of **1a** with LiNO_3 led to a high conversion of the starting material (*cf.* entries 1 and 23 in Table 1). However, the yield of target **2a** was only 56% due to the formation of significant amounts of by-products.

Using the procedure with chromium nitrate in THF (procedure i, Table 2), a series of 3-nitroxymethyl-substituted 1,2-oxazines and isoxazolines **2a–j** from the corresponding bis(ox)enamines **1a–j** were prepared. As can be seen from Table 2, the reaction is well-tolerated with various substituents in bis(ox)enamines **1** and usually provides products in good yields. The structure of compound **2g** was confirmed by single-crystal X-ray diffraction analysis.

Similar to **1a**, the major by-products in reactions with bis(ox)enamines **1b–i** were 3-hydroxymethyl-substituted 1,2-oxazines **3** (typically, not more than 15%) and products of tetrahydrofuran insertion **6** (5–10%), which in some cases were isolated and characterized. In the case of bis(ox)enamine **1j**, ether **6j** was isolated in 18% yield. Furthermore, diether **7j** resulting from formal insertion of two tetrahydrofuran molecules was detected in trace amounts by high-resolution mass spectrometry (Table 2).

The synthesis of nitrates **2** can be accomplished directly from the corresponding cyclic nitronates **8**, which are synthetic precursors of bis(ox)enamines **1** (Scheme 2, procedure ii). In this procedure, bis(ox)enamines are generated *in situ* by silylation of nitronates **8** with trimethylsilyl triflate and triethylamine, followed by treatment of the reaction mixture with chromium nitrate solution in tetrahydrofuran. Such a one-pot

Table 2 Reaction of cyclic bis(ox)enamines **1a–j** with chromium nitrate

^a The product contains a small amount of the 4,6-*cis*-isomer (dr 13 : 1), probably formed *via* acid-promoted epimerization of acetal center C-6.¹⁴

Scheme 2 One-pot synthesis of nitrates **2** from nitronates **8**.

process is operationally simpler, however the yield of product **2a** is somewhat lower compared to a two-step procedure with isolation of bis(ox)enamine **1a** (*cf.* Scheme 2, eqn (1) and entry 14 in Table 1). Still, the application of a one-pot

procedure is beneficial in cases when bis(oxy)enamine **1** is labile upon isolation (for example bis(oxy)enamine generated from nitronate **8k**, see Scheme 2, eqn (2)).

Procedure i did not prove to be applicable to acyclic bis(silyloxy)enamines **1l–o** (Schemes 3 and 4). In the corresponding experiments, only the formation of indecipherable product mixtures was observed. Interestingly, switching to anhydrous cobalt nitrate (procedure iii) in reaction with bis(oxy)enamine **1l** produced the desired labile trimethylsilyl ether of α -nitroso-oxime **2l** in 65% yield (Scheme 3). However, in reactions with acyclic bis(silyloxy)enamines **1m,o** the corresponding nitrates **2m,o** were identified in reaction mixtures by ^1H NMR and GC-MS in trace amounts (see the ESI †).

By conducting reactions with $\text{Co}(\text{NO}_3)_2$ in DMF, followed by desilylation with aqueous NaHSO_4 solution, labile α -nitroso-oximes **9** were obtained in reasonable yields (Scheme 4). In particular, by using this procedure, the simplest α -nitroso-oxime **9m** (2-(hydroxyimino)ethyl nitrate) was obtained from bis(oxy)enamine **1m** available from nitroethane. This product can be considered as a prospective intermediate in the synthesis of high-energy compounds. α -Nitroso-oximes **9m–o** are viscous liquids, which are unstable upon heating and slowly decompose at room temperature.

The mechanism of α -nitroso-oxime **2** formation deserves special discussion. In fact, depending on the nature of metal nitrate, the mechanism can be different. It is likely that the process involves initial Lewis acid-mediated cleavage of weak N–O bonds in initial bis(oxy)enamine **1**, and the subsequent addition of the nitrate anion to the resulting *N*-vinyl-*N*-alkoxy-nitrenium cation **A**¹⁵ (Scheme 5). This is confirmed by isolation of products **5** and **6**, which result from competitive addition of solvent to cation **A**. Thus, nitrates **2** are probably

Scheme 5 Plausible mechanism for the formation of α -nitroso-oxime ethers **2** from bis(oxy)enamines **1**.

formed as a result of $\text{S}_{\text{N}}1'$ substitution of the trimethylsilyloxy group in bis(oxy)enamines **1** for the nitrate anion.

The observed formation of α -hydroxy-oxime silyl ethers **4** can be explained by LA-mediated 1,3-migration of the trimethylsilyloxy group in initial bis(oxy)enamines **1**.^{15d} On the other hand, α -hydroxy-oxime cyclic ethers **3** may originate from either the addition of water to cation **A** or the hydrolysis of the corresponding trimethylsilyl ethers **4** (Scheme 5). The formation of an open-chain oxime **5a** in the reaction of **1a** with bismuth and lead nitrates (Table 1, entries 5 and 6) demonstrates the possibility of competitive coordination of these metals by *endo*- and *exo*-cyclic oxygen atoms in cyclic bis(oxy) enamines **1**.

Nitrate esters are frequently employed as intermediates in the total synthesis of pharmacologically relevant compounds.^{3,4b,c,7b,c,8a,b,16} Recently, we developed the synthesis of oxazolidinone **CMPO** (a highly potent phosphodiesterase 4 inhibitor) *via* the nitrate intermediate **2p** (Scheme 6).^{17a} The synthesis of nitrate **2p** was achieved by the nucleophilic substitution of bromine in 3-bromomethyl-substituted 1,2-oxazine **10p**. The latter was synthesized from cyclic nitronate **8p** with poor yield and conversion, as well as a high degree of epimerization of the acetal center C-6 (Scheme 6).^{17a} Employing the process developed here, we were able to optimize the synthesis of nitrate **2p** from nitronate **8p** by the silylation of the latter and treatment of the resulting bis(oxy)enamine **1p** with chromium nitrate. In this sequence, the yield of product **2p** is considerably higher and the degree of epimerization of C-6 is lower (*cf.* both approaches in Scheme 6). Unfortunately, one-pot synthesis of nitrate **2p** from nitronate **8p** using procedure ii was less efficient than the two-step procedure *via* isolation of enamine **1p** (Scheme 6).

Scheme 3 Synthesis of silyl ether **2l** from bis(oxy)enamine **1l**.

Scheme 4 Synthesis of α -nitroso-oximes **9m–o** from enamines **1m–o**.

Scheme 6 Two approaches to the synthesis of nitrate **2p** – key precursor of the PDE 4b inhibitor **CMPO**.

Conclusions

In conclusion, we have demonstrated that the reaction of readily available *N,N*-bis(oxy)enamines with metal nitrates results in the addition of a nitrate anion to a double carbon-carbon bond, with the elimination of the trimethylsilyloxy-group from the nitrogen atom. Using reactions of bis(oxy)enamines with chromium and cobalt nitrates, a general method for the synthesis of poorly accessible α -nitroxy-oximes of cyclic and acyclic structures was developed. These oximes are prospective NO donors and intermediates in the synthesis of bioactive molecules. The simplest α -nitroxy-oxime, 2-(hydroxyimino)ethyl nitrate, a potential intermediate in the synthesis of high energy materials, has been synthesized in two steps from nitroethane. The efficiency of the suggested method for the total synthesis of bioactive compounds was demonstrated by the optimization of the synthesis of the highly potent PDE 4 inhibitor.

Experimental

All reactions were performed in oven-dried (150°C) glassware. Tetrahydrofuran was distilled first from LiAlH_4 , stored under sodium benzophenone ketyl and distilled using the vacuum trap-to-trap technique prior to use. CH_2Cl_2 , MeCN, Et_3N , and $(\text{CH}_3)_3\text{SiBr}$ were distilled from CaH_2 . Hexane and EtOAc were distilled without drying agents. Pentane was commercial grade and used as received.

Inorganic reagents were commercial grade and were used as received. Anhydrous cobalt(II) nitrate was prepared by

thermal decomposition of the corresponding hexahydrate as described in ref. 18. Initial cyclic nitronates **8a**^{10c} and **8p**^{17b} were synthesized according to literature methods. Bis(oxy)enamines **1a**,^{10c} **b**,^{10h} **c**,^{10g} **d**,^{10f} **e**,^{10c} **f**,¹⁴ **g**,^{10c} **h**,^{10f} **i**,¹⁰ⁱ **j**,¹⁰ⁱ **11**,^{10e} and **1m-o**^{10d} were obtained by silylation of the corresponding nitronates according to previously published procedures.

Column chromatography was performed using Kieselgel 40–60 μm 60A. Analytical thin-layer chromatography was performed on silica gel plates with QF-254. Visualization was accomplished with UV light and a solution of anisaldehyde/ H_2SO_4 in ethanol.

1D and 2D NMR spectra were recorded at room temperature in CDCl_3 on a Bruker AM 300 spectrometer. The chemical shifts (^1H , ^{13}C) are given in ppm (δ) relative to the solvent signal, and liquid ammonia was used as a reference compound in the ^{14}N NMR spectra. Multiplicities are indicated by s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), and br (broad). Trichloroethylene was used as an internal standard in quantitative NMR measurements.

FTIR spectra were recorded on a Bruker Alpha-T spectrometer. Peaks in IR-spectra data are reported in cm^{-1} with the following relative intensities: s (strong), m (medium), w (weak), br (broad), and sh (shoulder). UV-VIS spectra were recorded on a Shimadzu UVmini-1240 spectrometer (data are reported in nm). Elemental analysis (average of two combustions) was performed by the Analytical Laboratory of the Institute of Organic Chemistry. HRMS were measured on an electrospray ionization (ESI) instrument with a time-of-flight (TOF) detector. GC-MS was performed on a Chromatec 5000 with the Agilent DB-1MS column 122-0132. EI mass spectra were recorded on a Finnigan MAT Incos 50 spectrometer (70 eV). Optical rotation

angles were measured on a JASCO P2000 polarimeter. Concentrations c are given in g per 100 mL. $[\alpha]_D$ values are given in $10^{-1} \text{ deg cm}^2 \text{ g}^{-1}$.

General procedure for the synthesis of nitrates 2a–j,p (procedure i)

To a stirred solution of Cr(NO₃)₃·9H₂O (0.8 g, 2.0 mmol) in THF (4 mL) was added 2 mL of 0.5 M solution of bis(oxy)enamines **1a–j,p**. The resulting solution was stirred for 2 h at room temperature and poured into a mixture of EtOAc (50 mL) and 0.25 M NaHSO₄ solution (50 mL). The aqueous layer was back-extracted with EtOAc (50 mL). Combined organic layers were washed with 0.25 M NaHSO₄ solution (50 mL), water (50 mL), and brine (50 mL), dried (Na₂SO₄), and evaporated in a vacuum. The residue was subjected to column chromatography on silica gel to give nitrates **2a–j,p**. For determining analytical properties, products were recrystallized from pentane/Et₂O mixtures.

General procedure for the synthesis of nitrates 2a,k from cyclic nitronates 8 (procedure ii)

To a stirred solution of nitronates **8a,k** (1.0 mmol) and triethylamine (0.17 mL, 1.2 mmol) in CH₂Cl₂ (3 mL) was added trimethylsilyl triflate (0.2 mL, 1.1 mmol) at -78°C under an argon atmosphere. After stirring the reaction mixture for 2 h at -78°C , a solution of Cr(NO₃)₃·9H₂O (0.8 g, 2.0 mmol) in THF (4 mL) was added *via* a syringe and the cooling bath was removed. After 2 h the resulting dark-colored solution was poured into a mixture of EtOAc (50 mL) and 0.25 M NaHSO₄ solution (50 mL). The aqueous layer was back-extracted with EtOAc (50 mL). Combined organic layers were washed with 0.25 M NaHSO₄ solution (50 mL), water (50 mL), and brine (50 mL), dried (Na₂SO₄), and evaporated in a vacuum. The residue was subjected to column chromatography on silica gel to give nitrates **2a,k** as well as by-products **6a** and **3k**, **6k**, respectively.

(6,6-Dimethyl-4-phenyl-5,6-dihydro-4*H*-1,2-oxazin-3-yl)methyl nitrate (2a). Yields: 71% (procedure i), 62% (procedure ii). White solid. Mp 50–51 °C. $R_f = 0.7$ (EtOAc/hexane = 1 : 1). ¹H NMR (CDCl₃, 300.13 MHz): 1.31 and 1.41 (2 s, 6 H, 2 CH₃), 1.95 (dd, $J = 12.0, 13.5 \text{ Hz}$, 1 H, H_{ax}C-5), 2.13 (dd, $J = 7.8, 13.5 \text{ Hz}$, 1 H, H_{eq}C-5), 3.51 (dd, $J = 7.8, 12.0 \text{ Hz}$, 1 H, H_{ax}C-4), 4.75 (d, $J = 12.4 \text{ Hz}$, 1 H, HC-ONO₂), 4.84 (d, $J = 12.4 \text{ Hz}$, 1 H, HC-ONO₂), 7.22 (d, $J = 6.7 \text{ Hz}$, 2 H, *o*-C₆H₅), 7.32–7.38 (m, 3 H, *m*- and *p*-C₆H₅). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 22.6 and 28.3 (2 CH₃), 37.8 (CH-4), 39.7 (CH₂-5), 72.0 (CH₂-ONO₂), 75.7 (C-6), 127.9, 128.1 and 129.4 (*o*-, *m*- and *p*-C₆H₅), 138.6 (*i*-C₆H₅), 151.3 (C=N). ¹⁴N NMR (CDCl₃, 21.69 MHz): -45.0 . FTIR (KBr): 1643 (s, ν_{as} ONO₂). UV-VIS (CH₂Cl₂): λ_{max} , nm 203,

Reactions of model bis(oxy)enamine **1a** with metal nitrates

To a stirred solution of metal nitrate (0.5 mmol) in 1 mL of solvent indicated in Table 1 was added 0.5 ml of 0.5 M solution of bis(oxy)enamine (0.25 mmol) in CH₂Cl₂. The mixture was stirred at r.t. for the time indicated in Table 1, and then poured into a mixture of EtOAc (25 mL) and 0.25 M NaHSO₄ solution (25 mL). The aqueous layer was back-extracted with EtOAc (25 mL). Combined organic layers were washed with 0.25 M NaHSO₄ solution (25 mL), water (25 mL), and brine (25 mL), dried (Na₂SO₄), and evaporated in a vacuum. The residue was analyzed by ¹H NMR with an internal standard. ¹H NMR of by-product **3a** is in accordance with published data.^{10h} A sample of pure **4a** was prepared by standard silylation (r.t., 18 h) of **3a** (0.3 mmol) with (CH₃)₃SiCl (0.6 mmol)/Et₃N (0.75 mmol) in CH₂Cl₂ (1 mL) followed by evaporation and extraction of the product with pentane (yield: 99%). M.p. = 51–55 °C. ¹H NMR (CDCl₃, 300.13 MHz): -0.04 (s, 9 H, (CH₃)₃Si), 1.33 and 1.37 (2 s, 6 H, 2 CH₃), 1.90 (dd, *J* = 12.8, 12.2 Hz, 1 H, HC-5), 2.11 (dd, *J* = 12.8, 8.1 Hz, 1 H, HC-5), 3.66 (dd, *J* = 12.2, 8.1 Hz, 1 H, HC-4), 3.95 (d, *J* = 11.7 Hz, 1 H, CHO), 4.03 (d, *J* = 11.7 Hz, 1 H, CHO), 7.10–7.38 (m, 5 H, *o*-, *m*-, *p*-C₆H₅). ¹³C NMR (CDCl₃, 75.47 MHz, HSQC): -0.37 ((CH₃)₃Si), 22.9 and 28.6 (2 CH₃), 36.9 (CH-4), 40.6 (CH₂-5), 63.0 (CH₂-O), 74.5 (C-6), 127.1, 128.6 and 128.8 (*o*-, *m*-, *p*-C₆H₅), 140.5 (*i*-C₆H₅), 158.0 (C=N). ²⁹Si NMR (CDCl₃, 59.63 MHz): 19.9. HRMS: *m/z* Calcd for [C₁₆H₂₆NO₂Si]⁺ 292.1727 ([M + H]⁺). Found: 292.1725.

5-Hydroxy-2-(hydroxyimino)-5-methyl-3-phenylhexyl formate (5a). To a stirred solution of Bi(NO₃)₃·5H₂O (0.485 g, 1.0 mmol) in DMF (2.0 mL) was added 1.0 mL of 0.5 M solution of bis(oxy)enamine **1a** (0.5 mmol) in CH₂Cl₂ at r.t. The mixture was stirred for 2.5 h at r.t. and then diluted with AcOEt (5 mL) and poured into a mixture of AcOEt (50 mL) and 0.25 M aqueous solution of NaHSO₄ (50 mL). The aqueous layer was back-extracted with AcOEt (50 mL). Combined organic layers were washed with water (30 mL), and brine (30 mL), dried (Na₂SO₄), and evaporated in a vacuum. The residue was subjected to column chromatography on silica gel (eluent: hexane/AcOEt = 10 : 1 → 5 : 1 → 1 : 1) to give 0.045 g (34%) of **5a**. Colorless oil. A mixture of *E*,*Z*-isomers, ratio 12 : 1.0. *R*_f = 0.38, 0.32 (2 isomers, EtOAc/hexane = 1 : 1). *E*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 1.26 and 1.30 (2 s, 6 H, 2 CH₃), 1.84 (dd, *J* = 15.0, 3.8 Hz, 1 H, HC-5), 2.1 (br, 1 H, OH), 2.48 (dd, *J* = 15.0, 10.9 Hz, 1 H, HC-5), 3.98 (dd, *J* = 10.9, 3.8 Hz, 1 H, HC-4), 4.58 (d, *J* = 14.6 Hz, 1 H, HC-O), 5.17 (d, *J* = 14.6 Hz, 1 H, HC-O), 7.12–7.38 (m, 5 H, *o*-, *m*-, *p*-C₆H₅), 7.91 (s, 1 H, HC=O), 10.7 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 27.9 and 31.5 (2 CH₃), 45.1 (CH-4), 47.3 (CH₂-5), 57.4 (CH₂O), 70.6 (C-6), 127.2, 127.9 and 129.2 (*o*-, *m*-, *p*-C₆H₅), 141.6 (*i*-C₆H₅), 156.9 (C=N), 160.0 (HC=O). *Z*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 1.39 and 1.47 (2 s, 6 H, 2 CH₃), 2.1 (br, 1 H, OH), 2.14 (dd, *J* = 12.8, 3.8 Hz, 1 H, HC-5), 2.58 (dd, *J* = 12.8, 12.6 Hz, 1 H, HC-5), 3.53 (m, 1 H, HC-4), 4.76

(d, $J = 14.7$ Hz, 1 H, HC-O), 5.53 (d, $J = 14.7$ Hz, 1 H, HC-O), 7.12–7.38 (m, 5 H, *o*-, *m*-, *p*-C₆H₅), 7.91 (s, 1 H, HC=O), 10.7 (br, 1 H, OH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT, characteristic signals): 40.3 and 43.7 (CH-4 and CH₂-5), 63.3 (CH₂O). Both isomers: HRMS: m/z Calcd for [C₁₄H₂₀NO₄]⁺ 266.1387 ([M + H]⁺). Found: 266.1377.

2-Phenyl-2-(trimethylsilyloxyimino)ethyl nitrate (2l) (procedure iii). To a stirred solution of anhydrous Co(NO₃)₂ (0.366 g, 2.0 mmol) in THF (4 mL) was added 2 mL of 0.5 M solution of bis(trimethylsilyloxy)enamine **1l**. The resulting solution was stirred for 2 h at room temperature and poured into a mixture of EtOAc (50 mL) and saturated aqueous solution of K₂CO₃ (50 mL). The aqueous layer was back-extracted with EtOAc (50 mL). Combined organic layers were washed sequentially with saturated aqueous solution of K₂CO₃ (50 mL), water (50 mL), and brine (50 mL), dried (Na₂SO₄), and evaporated in a vacuum. The residue was dissolved in diethyl ether and filtered through a short column filled with charcoal (0.5 cm) and Celite (0.5 cm) layers to remove polymer products and traces of inorganic salts. The filtrate was evaporated to give 202 mg (65%) of oxime **2l** as yellowish oil unstable at r.t. Purity *ca.* 85% (according to ¹H NMR with internal standard). A mixture of *Z/E*-isomers, ratio 9:1. *Z*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 0.35 (s, 9 H, (CH₃)₃Si), 5.69 (s, 2 H, CH₂-ONO₂), 7.39–7.46 and 7.63–7.67 (2 m, 4 H and 1 H, *o*-, *m*-, *p*-C₆H₅). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): -0.76 ((CH₃)₃Si), 64.3 (CH₂-ONO₂), 126.8, 128.6 and 129.9 (*o*-, *m*-, *p*-C₆H₅), 132.9 (*i*-C₆H₅), 154.8 (C=N). ²⁹Si NMR (CDCl₃, 59.63 MHz): 28.4. ¹⁴N NMR (CDCl₃, 21.69 MHz): -44.7. *E*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz, characteristic signals): 0.34 (s, 9 H, (CH₃)₃Si), 5.37 (s, 2 H, CH₂-ONO₂). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT, characteristic signals): -0.64 ((CH₃)₃Si), 62.2 (CH₂-ONO₂). Both isomers: FTIR (thin layer): 1644 (s, ν_{as} ONO₂). MS (EI): m/z (%) = 268 (8) [M]⁺, 207 (95) [M - CH₃ - NO₂]⁺, 192 (73) [M - CH₂ONO₂]⁺, 103 (20) [M - Ph - CH₂ONO₂]⁺, 77 (26) [Ph]⁺, 73 (100) [(CH₃)₃Si]⁺.

Synthesis of acyclic α -nitroxoximes **9m–o** (procedure iv)

To a stirred solution of anhydrous Co(NO₃)₂ (0.732 g, 4.0 mmol) in a mixture of DMF (4 mL) and CH₂Cl₂ (4 mL) was added 4 mL of 1 M solution of bis(trimethylsilyloxy)enamines **1m–o** (4.0 mmol) in CH₂Cl₂ at r.t. under an argon atmosphere. The mixture was stirred for 2.5 h at r.t., then poured into a mixture of AcOEt (100 mL) and 0.25 M aqueous solution of NaHSO₄ (100 mL) and intensively shaken for *ca.* 5 min. The aqueous layer was back-extracted with EtOAc (50 mL). The combined organic layers were washed with a 0.25 M aqueous solution of NaHSO₄ (70 mL), water (70 mL), and brine (70 mL), dried (Na₂SO₄), and concentrated in a vacuum. The residue was dissolved in 5 mL of Et₂O. Water (1 mL) was added and the mixture was intensively shaken for 1 min. The organic layer was separated and the water phase was washed with 5 mL of Et₂O. Combined organic layers were dried over Na₂SO₄ and the volatiles were evaporated. The residue was dried in a vacuum (10 Torr) to give α -nitroxoximes **9m–o**. **Caution!** Low molecular weight organic nitrates

are explosive. No attempts to prepare more than 0.2 g were made.

2-(Hydroxyimino)ethyl nitrate (9m). A yellowish volatile liquid unstable upon heating and chromatography (purity *ca.* 90% determined by ¹H NMR with internal standard). Yield: 32% (with respect to purity). A mixture of *E/Z*-isomers, ratio 1.4:1. *E*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 5.05 (d, $J = 5.5$ Hz, 2 H, CH₂ONO₂), 7.54 (t, $J = 5.5$ Hz, 1 H, =CH), 8.39 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 68.6 (CH₂ONO₂), 143.7 (C=N). *Z*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 5.29 (d, $J = 3.7$ Hz, 2 H, CH₂ONO₂), 6.91 (t, $J = 3.7$ Hz, 1 H, =CH), 8.74 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 65.8 (CH₂ONO₂), 145.1 (C=N). Both isomers: ¹⁴N NMR (CDCl₃, 21.69 MHz): -45.8. FTIR (thin layer): 3306 (s, br, OH), 2917 (m, CH), 1645 (s, ν_{as} ONO₂), 1426 (m), 1277 (s), 935 (m, sh), 852 (s). MS (EI): $m/z = 76$ [CH₂ONO₂]⁺, 58 [M - NO₃]⁺, 57 [M - HNO₃]⁺, 46 [NO₂]⁺, 44 [M - CH₂ONO₂]⁺.

2-(Hydroxyimino)propyl nitrate (9n). A yellowish volatile liquid unstable upon heating and chromatography (purity *ca.* 80% determined by ¹H NMR with internal standard). Yield: 25% (with respect to purity). A mixture of *E/Z*-isomers, ratio 6.3:1. *E*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 1.98 (s, CH₃), 4.98 (s, CH₂ONO₂), 9.12 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 12.0 (CH₃), 73.1 (CH₂ONO₂), 151.2 (C=N). *Z*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 1.96 (s, CH₃), 5.33 (s, CH₂ONO₂), 9.12 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT, characteristic signals): 15.7 (CH₃), 64.5 (CH₂ONO₂). Both isomers: ¹⁴N NMR (CDCl₃, 21.69 MHz): -45.2. FTIR (thin layer): 3272 (s, br, OH), 2923 (m, CH), 1730 (m), 1644 (s, ν_{as} ONO₂), 1438 (m), 1288 (s), 945 (m, sh), 921 (m), 851 (s). MS (EI): $m/z = 135$ [M + H]⁺, 76 [CH₂ONO₂]⁺, 58 [M - NO₃]⁺, 46 [NO₂]⁺, 44 [M - CH₂ONO₂]⁺.

Methyl 4-(hydroxyimino)-5-(nitroxy)pentanoate (9o). Yellowish oil unstable upon heating and chromatography (purity *ca.* 70% determined by ¹H NMR with internal standard). Yield: 27% (with respect to purity). Column chromatography (hexane/EtOAc = 5:1) on silica gel at -15 °C provided a sample of individual **12c**, which was used for further analysis. A mixture of *E/Z*-isomers, ratio 3.8:1. $R_f = 0.55$ (EtOAc/hexane = 1:1). *E*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 2.50–2.70 (m, 4 H, CH₂-CH₂), 3.70 (s, 3 H, OCH₃), 5.07 (s, 2 H, CH₂ONO₂), 9.18 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 22.0 and 29.7 (CH₂-CH₂), 52.0 (OCH₃), 72.5 (CH₂ONO₂), 153.0 (C=N), 173.2 (C=O). *Z*-Isomer: ¹H NMR (CDCl₃, 300.13 MHz): 2.50–2.70 (m, 4 H, CH₂-CH₂), 3.80 (s, 3 H, OCH₃), 5.33 (d, $J = 3.7$ Hz, 2 H, CH₂ONO₂), 9.03 (br, 1 H, NOH). ¹³C NMR (CDCl₃, 75.47 MHz, DEPT): 25.7 and 29.9 (CH₂-CH₂), 52.0 (OCH₃), 66.8 (CH₂ONO₂), 155.1 (C=N), 173.9 (C=O). Both isomers: ¹⁴N NMR (CDCl₃, 21.69 MHz): -45.2. FTIR (thin layer): 3382 (s, br, OH), 2957 (m, sh, CH), 1733 (s, C=O), 1644 (s, ν_{as} ONO₂), 1440 (m), 1368 (m), 1283 (s, sh), 1203 (m), 1176 (m), 983 (m, sh), 851 (s), 640 (w). HRMS: m/z Calcd for [C₆H₁₀N₂O₆Na]⁺ 229.0431 ([M + Na]⁺). Found: 229.0434. MS (EI): $m/z = 206$ [M]⁺.
