[www.rsc.org/obc](http://www.rsc.org/obc)

[2.2]Paracyclophane-1,9-dienes substituted with *n*-octyl chains have been synthesised from the corresponding dithia[3.3]paracyclophanes using a benzyne induced Stevens rearrangement. The use of 2-(trimethylsilyl)phenyl trifluoromethanesulfonate and tetra-*n*-butylammonium fluoride as the *in situ* benzyne source gave significantly improved yields over traditional sources of benzyne and enabled the preparation of *n*-octyl substituted [2.2]paracyclophane-1,9-dienes on a multi-gram scale.

## Introduction

[2.2]Paracyclophanes have received considerable attention due to their confined molecular motions and the close proximity of the two stacked phenylene groups.<sup>1–3</sup> This restricted geometry gives rise to unique electronic and optical properties, characteristic NMR spectra and applications in asymmetric catalysis for planar chiral derivatives.<sup>4–10</sup> Linking of the phenylene groups by two *cis*-vinylene bonds in [2.2]paracyclophane-1,9-diene (**1**) results in extensive steric repulsion, with an intramolecular distance of just 2.85 Å between the phenylene group bridge head carbons.<sup>11</sup> The high ring strain of this class of molecules, calculated to be 176 kJ mol<sup>–1</sup> for cyclophanediene **1**, makes them interesting monomers in polymer science.<sup>2,12,13</sup> Specifically, alkoxy-substituted [2.2]paracyclophane-1,9-dienes have been used in ruthenium carbene initiated ring opening metathesis polymerisation (ROMP), forming soluble poly(phenylenevinylene)s (PPVs).<sup>14–18</sup> These conjugated polymers have been extensively studied for application in electronic and optoelectronic devices, and recently in fluorescence imaging.<sup>19–22</sup> Traditionally alkoxy groups have been appended to the polymer backbone to improve solubility, however, this results in a significant red-shift of the emission of these poly-

mers over that of the parent unsubstituted PPV.<sup>23</sup> By contrast alkyl substituted PPVs show minimal change in the energy of the band gap, in comparison to the parent PPV, whilst providing the required solubility.<sup>24</sup>

The introduction of alkyl groups on the phenylene groups of **1** has not been reported. It is of interest as PPVs prepared by the ROMP of [2.2]paracyclophane-1,9-dienes show greater control of the polymer structure, molecular weight and enable the preparation of block copolymers.<sup>14</sup>

Synthetic routes towards [2.2]paracyclophane-1,9-dienes are extremely limited (Scheme 1).<sup>25–28</sup> Boekelheide *et al.* reported a route from dithia[3.3]paracyclophane (**2**) that uses a benzyne induced Stevens rearrangement (BSR) to contract the dithiacyclophane ring (**3**), followed by oxidation of the phenyl sulfides (**4**) and a thermal *syn*-elimination to obtain **1**.<sup>25</sup> Recently Pasini *et al.* described a synthesis of **1** from **2** that involved a Pummerer rearrangement to give **5**, followed by ring contraction through photochemical sulfur extrusion to give **6** and a final thermal elimination of the acetate groups to produce **1**.<sup>26</sup> The BSR route generally gives low yields of the desired paracyclophanediene, whereas the Pummerer rearrangement gives improved yields but has been demonstrated only for synthesis of the parent [2.2]paracyclophane-1,9-diene and not for the substituted derivatives that are required to form soluble PPVs. The route of Boekelheide *et al.* utilises the diazotization of anthranilic acid with isoamyl nitrite as the *in situ* source of benzyne. A more convenient source of benzyne has been reported through the reaction of 2-(trimethylsilyl)phenyl trifluoromethanesulfonate (**7**) with tetra-*n*-butylammonium fluoride (TBAF).<sup>29,30</sup> This system offers a wider substrate scope, less toxic reagents, milder reaction conditions and much greater yields.<sup>31,32</sup>

In our previous reports on the synthesis of tetraoctyloxy-substituted [2.2]paracyclophane-1,9-dienes we have used the method of Boekelheide *et al.*, however, only low yields (<31%) were obtained.<sup>33</sup> Herein we report an improved process to prepare substituted [2.2]paracyclophane-1,9-dienes using **7** and TBAF·3H<sub>2</sub>O as the benzyne source and the use of this process to

prepare [2.2]paracyclophane-1,9-dienes with alkyl side chains, an important precursor to alkyl substituted PPVs by ROMP.

## Results and discussion

### Synthesis of 2-(trimethylsilyl)phenyl trifluoromethanesulfonate

Benzyne precursor 7 offers major advantages over traditional sources of benzene, but it is exceptionally expensive. Consequently, a method to prepare compound 7 on a large scale was developed and this was adapted from a procedure reported by Brimble *et al.*<sup>34</sup> The procedure involved the protection of the hydroxy group of 2-chlorophenol with TMSCl, followed by a retro-Brook rearrangement in the presence of molten sodium.<sup>35</sup> Reaction of 2-(trimethylsilyl)phenol with trifluoromethanesulfonic anhydride gave compound 7 in a good yield (overall 78%). The procedure could be scaled to provide multi-gram quantities (experimental procedure in ESI†).

### Synthesis of 4,7-dioctyl-[2.2]paracyclophane-1,9-diene

The initial step in the synthesis of 4,7-dioctyl-[2.2]paracyclophane-1,9-diene (15) and the two isomeric cyclophanedienes; 4,7,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene (20) and 5,8,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene (21) is the synthesis of 1,4-bis(bromomethyl)-2,5-bis(octyl)benzene (9). Preparation of compound 9 required the incorporation of two bromomethyl groups on the 2,5-positions of dioctylbenzene (8) and this was achieved by adapting the procedure of Tanaka *et al.* (Scheme 2).<sup>36</sup> Compound 8 was heated at reflux in acetic acid with HBr and paraformaldehyde, over 5 days to give 9 in a single step (see ESI†).

5,8-Dioctyl-2,11-dithia[3.3]paracyclophane (12) was prepared by the intramolecular cyclisation between an equimolar amount of 1,4-benzenedimethanethiol (11) and 9 (Scheme 2). A toluene solution of the two coupling components was added dropwise to a large volume of ethanol containing KOH. A slow addition is required to prevent oligomerisation. After column chromatography dithiacyclophane 12 was obtained as a colourless viscous oil in a yield of 43%.

The BSR of dithiacyclophane 12 was performed by the slow addition of TBAF·3H<sub>2</sub>O to a THF solution of 7 and 12 (Scheme 3). Isolation of the mixture of phenyl sulfides (13) was

Scheme 2 Synthesis of dithia[3.3]paracyclophanes; 12, 16 and 17, R = n-octyl.

Scheme 3 Synthesis of [2.2]paracyclophane-1,9-diene 15, R = n-octyl.

achieved using simple filtration through silica to remove biphenylene (by-product from the dimerisation of benzene). Compound **13** was obtained as a highly viscous yellow oil in a yield of 67%. The analogous reaction with isoamyl nitrite and anthranilic acid in 1,2-dichloroethane gave **13** in a yield of only 25% (ESI).

Oxidation of the phenyl sulfides to the corresponding phenyl sulfoxides (**14**) was performed using aqueous  $H_2O_2$  in acetic acid and toluene at room temperature. Compound **14** was isolated as a highly viscous oil in a yield of 96% after work-up, with no further purification performed. The thermal *syn*-elimination of the phenyl sulfoxide groups of compound **14** to obtain the corresponding *cis*-vinylene bonds of **15** was performed by refluxing in a mixture of xylenes in the presence of  $Cs_2CO_3$ . The addition of  $Cs_2CO_3$  gave slightly improved yields, presumably due to reaction of the acidic by-products of the elimination reaction. Purification by column chromatography gave cyclophanediene **15** as a clear oil in a yield of 57%.

#### Synthesis of 4,7,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene and 5,8,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene

The synthesis of tetraoctyl-substituted [2.2]paracyclophane-1,9-dienes; **20** and **21** required the conversion of compound **9** to dithiol compound **10**, to introduce *n*-octyl groups on to both phenylene groups. This was achieved by the reaction of **9** with thiourea followed by hydrolysis of the intermediate isothiouronium salt and acidification. Dithiacyclophanes **16** and **17** were prepared by the same procedure as described for dithiacyclophane **12** by the slow addition of a toluene solution containing an equimolar amount of **9** and **10**, to a large volume of ethanol containing KOH (Scheme 2). Purification by column chromatography gave a mixture of dithiacyclophanes **16** and **17** as a colourless solid in a combined yield of 40%. Integration of the  $ArCH_2S$  groups in the  $^1H$  NMR spectrum gave a ratio of **16** : **17** of 6 : 94. In relation to the synthesis of tetraoctyloxy-substituted [2.2]paracyclophane-1,9-dienes, performing the BSR on a single dithiacyclophane resulted in the formation of both cyclophanediene isomers, after the final *syn*-elimination, as a consequence of isomerisation in this reaction.<sup>33</sup> Consequently,

separation of **16** and **17** was not conducted due to this expected isomerisation.<sup>33</sup>

The mixture of dithiacyclophanes **16** and **17** was subjected to the BSR with compound **7** and  $TBAF \cdot 3H_2O$  (Scheme 4). After column chromatography the mixture of phenyl sulfides (**18**) was isolated as a viscous yellow oil in a yield of 83%. The analogous reaction with isoamyl nitrite and anthranilic acid in 1,2-dichloroethane gave **18** in a yield of only 32% (ESI). Oxidation of the phenyl sulfides of **18** to give **19** was performed with aqueous  $H_2O_2$  in toluene and acetic acid in an excellent yield (95%). Heating compound **19** at reflux in a mixture of xylenes with  $Cs_2CO_3$  resulted in the thermal *syn*-elimination of the phenyl sulfoxide groups and the formation of cyclophanedienes **20** and **21**. Purification by column chromatography gave cyclophanedienes **20** and **21** as a colourless oil in a combined yield of 45%. Integration of the phenylene group hydrogens in the  $^1H$  NMR spectrum gave the ratio of **20** : **21** to 17 : 83. Preparative separation of the two isomers was not possible through column chromatography, HPLC or recrystallisation (see ESI†). However, a single crystal of **20** was obtained for X-ray crystallography through multiple fractional crystallisations from hexane, at  $-10^{\circ}C$ .

#### Characterisation of intermediates **12**, **13**, **14** and 4,7-dioctyl-[2.2]paracyclophane-1,9-diene (**15**)

Dithia[3.3]paracyclophanes and [2.2]paracyclophane-1,9-dienes, where at least one phenylene group is substituted, are planar chiral as a consequence of restricted rotation of the phenylene group through the dithiacyclophane ring. Substitution with *n*-octyl chains causes both the methylene hydrogens of the alkyl chain and of the thioether bonds to become diastereotopic. The  $^1H$  NMR spectrum of dithiacyclophane **12** (Fig. 1a) showed two hydrogen environments for the unsubstituted phenylene group, which were observed as AA'XX' spin systems at 6.96 and 6.86 ppm. The hydrogens of the substituted phenylene group appear as a singlet at 6.64 ppm. Due to the planar chirality of these molecules the methylene hydrogens of the thioether bridges are diastereotopic and four doublets are observed, between 3.83–3.62 ppm, for the 8 hydrogens.

Scheme 4 Synthesis of [2.2]paracyclophane-1,9-dienes **20** and **21**,  $R = n$ -octyl.

Fig. 1  $^1\text{H}$  NMR spectra ( $\text{CDCl}_3$ ) of (a) dithia[3.3]paracyclophane 12 and (b) [2.2]paracyclophane-1,9-diene 15.

A large difference in chemical shift is observed between the two diastereotopic methylene hydrogens bonded to the substituted phenylene group. This is a consequence of the close proximity of one of these hydrogens to the *n*-octyl chain. The methylene hydrogens adjacent to the unsubstituted phenylene group have a similar chemical shift and appear close to the equivalent hydrogens in the unsubstituted dithiacyclophane 2.<sup>26</sup> The hydrogens of the methylene group of the *n*-octyl chain adjacent to the phenylene group are also diastereotopic and appear as doublet of doublets at 2.71 and 2.44 ppm.

The  $^1\text{H}$  NMR spectrum of compound 13 exhibited a complex range of signals and complete characterisation was not possible. This is a consequence of the BSR not being regioselective and migration of the phenyl sulfide groups occurring to either carbon of the thioether bond. Consequently each of these carbon centres becomes a stereogenic centre and a large number of regio and stereoisomers are possible. The success of the BSR was confirmed by mass spectrometry (MS) with the molecular ion observed at 650 Da ( $m/z$ ) and through the fragmentation species by loss of a phenyl group and a phenyl sulfide group. Characterisation of phenyl-sulfoxide compound 14 by  $^1\text{H}$  NMR spectroscopy again proved difficult due to the large number of possible stereoisomers, and this was further complicated as each sulfoxide group is also a stereocentre. FT-IR spectroscopy confirmed the oxidation of the sulfide group through an intense absorbance observed at  $1041\text{ cm}^{-1}$ ,

which corresponded to the  $\text{S}=\text{O}$  stretch. Over oxidation to the sulfone did not occur to any significant degree, as minimal absorbances are observed between  $1160\text{--}1120\text{ cm}^{-1}$ , that are characteristic for this group.<sup>37</sup> MS measurements showed major molecular ions at 681 and 556 Da ( $m/z$ ) which corresponded to the expected species and the fragmentation species by loss of a phenyl sulfoxide group, respectively.

The  $^1\text{H}$  NMR spectrum of cyclophane-1,9-diene 15 (Fig. 1b) showed two hydrogen environments for the *cis*-vinylenes at 7.08 and 7.04 ppm. The two hydrogen environments of the unsubstituted phenylene group appear as two AA'XX' spin systems at 6.71 and 6.42 ppm, and the hydrogens of the substituted phenylene group appear as a upfield singlet at 6.11 ppm. As with dithiacyclophane 12 the hydrogens of the methylene group of the *n*-octyl chain bonded to the phenylene group are diastereotopic and appear as two sets of doublet of triplets at 2.55 and 2.23 ppm. The loss of the sulfoxide group was confirmed by FT-IR spectroscopy with no intense absorbance at  $1041\text{ cm}^{-1}$ . Further, an absorbance at  $690\text{ cm}^{-1}$  was associated with the out-of-plane stretch of the C-H bond of the *cis*-vinylene bond. High resolution MS (HR-MS) observed the molecular ion corresponding to 15 at 429.3510 Da ( $m/z$ ) (calc. 429.3516).

#### Characterisation of intermediates 16, 17, 18, 19 and 4,7,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene (20) and 5,8,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene (21)

The tetra-octyl substituted dithiacyclophane 17 is planar chiral as previously described for the dithiacyclophane 12. However, as dithiacyclophane 16 exhibits a plane of symmetry it is not chiral. The  $^1\text{H}$  NMR spectrum (Fig. 2a) of mixture of dithiacyclophanes 16 and 17 shows two singlets at 6.76 and 6.78 ppm, respectively, which correspond to the four equivalent hydrogens of the phenylene groups of each isomer. The hydrogens of methylene groups of the thioether bond are diastereotopic and two doublets are observed at 4.07 and 3.57 ppm for 16 and at 3.82 and 3.63 ppm for 17. The chemical shift difference between the two diastereotopic hydrogens of 16 is 0.50 ppm, whereas, for 17 a difference of just 0.19 ppm is observed. The multiplets between 2.82–2.69 and 2.48–2.35 ppm are assigned to the hydrogens of the methylene groups of the *n*-octyl chains adjacent to the phenylene group in both 16 and 17. As expected the product of the BSR, compound 18, exhibits a complex  $^1\text{H}$  NMR spectrum and as with 13 complete characterisation was not possible. MS confirmed the BSR with the molecular ion of the expected product observed at 874 Da ( $m/z$ ). Additional mass ions were observed that correspond to the fragmentation species by the loss of a phenyl group and a phenyl sulfide group.

After oxidation characterisation of the phenyl-sulfoxide compound 19 by NMR spectroscopy again proved difficult, however, a higher chemical shift of the phenyl sulfoxide groups was observed, in comparison to the phenyl sulfide group of 18. Oxidation was confirmed by FT-IR spectroscopy by the absorbance of the  $\text{S}=\text{O}$  stretch at  $1044\text{ cm}^{-1}$ . Over oxidation to the sulfone again was not detected. MS showed the

Fig. 2  $^1\text{H}$  NMR spectra ( $\text{CDCl}_3$ ) of (a) dithia[3.3]paracyclophanes **16** and **17**, and (b) [2.2]paracyclophane-1,9-dienes **20** and **21**,  $\text{R} = n\text{-octyl}$ .

presence of the oxidised product at 906 Da ( $m/z$ ) corresponding to the expected molecular species and the fragmentation species by loss of a phenyl sulfoxide group at 780 Da ( $m/z$ ).

The  $^1\text{H}$  NMR spectrum of the mixture of cyclophanedienes **20** and **21** (Fig. 2b) showed the four hydrogens of the phenylene groups of each isomer to appear as singlets at 6.10 and 6.34 ppm, respectively. The four equivalent *cis*-vinylene hydrogens are observed as singlets at 7.07 ppm for **20** and at 6.92 ppm for **21**. The hydrogens of the methylene group of the octyl chain bonded to the phenylene group are diastereotopic and are observed in cyclophanediene **20** as two doublets of triplets at 2.59 and 2.31 ppm. In cyclophanediene **21** the equivalent hydrogens appear as two doublets of triplets at 2.52 and 2.15 ppm. HR-MS of the mixture of isomers **20** and **21** observed the molecular ion at 652.5925 Da ( $m/z$ ) (calc. 652.5942).

#### Solid-state structure of 4,7,12,15-tetraoctyl-[2.2]paracyclophane-1,9-diene

The solid-state structure of cyclophanediene **20** was determined by X-ray crystallography (Fig. 3). The intramolecular distance between the two carbon atoms of the phenylene groups bonded to the *n*-octyl group is 3.21 Å, whilst the equivalent distance between the two unsubstituted carbons is 3.13 Å. The intramolecular distance between the two carbons of the

Fig. 3 Solid-state structure of **20** as ORTEP plot. Hydrogen atoms are omitted for clarity.

phenylene group bonded to the vinylene bond is shorter at 2.80 Å.

The highly strained nature of the molecule is shown by the large distortion in the phenylene groups as the carbon atoms bonded to the vinylene bond lie between 0.17 and 0.21 Å out of the plane of the ring. The vinylene bond length is 1.34 Å, which is in agreement with that of a standard *cis*-vinylene bond 1.32 Å.<sup>38</sup> In comparison to the unsubstituted cyclophanediene **1**, no significant differences in the intramolecular distances of the phenylene groups are present and a comparable vinylene bond length of 1.33 Å is observed.<sup>11</sup>

## Conclusion

[2.2]Paracyclophane-1,9-dienes substituted with two and four *n*-octyl chains have been prepared from the corresponding dithia[3.3]paracyclophanes. The use of benzyne precursor **7** and TBAF·3H<sub>2</sub>O as the *in situ* source of benzyne in the BSR gave significantly improved yields over the traditional source of anthranilic acid and isoamyl nitrite. A yield of 67% was obtained for **13** and 83% for **18**, in comparison to 25 and 32% from the traditional reaction. The tetraoctyl substituted [2.2]paracyclophane-1,9-dienes were isolated as a mixture of the structural isomers **20** and **21** in ratio of 17:83. A single crystal of **20** was obtained by fractional crystallisation and the highly strained nature of this molecule was shown from the solid state structure by the large distortion of the bridging atoms of the phenylene group from the plane of the ring. The ability to prepare these alkyl substituted cyclophanedienes on a multi-gram scale offers great potential in polymer science where they can be subjected to ROMP to obtain PPVs with semiconducting and fluorescent properties.

## Experimental

### Methods

Nuclear magnetic resonance (NMR) spectra were obtained on Bruker spectrometers operating at either 300, 400 or 500 MHz, for <sup>1</sup>H nuclei and 75, 101 or 126 MHz for <sup>13</sup>C nuclei. Chemical shifts are reported in ppm relative to the indicated residual solvent (<sup>1</sup>H NMR spectroscopy: CDCl<sub>3</sub>;  $\delta$  = 7.26 ppm and <sup>13</sup>C NMR spectroscopy: CDCl<sub>3</sub>;  $\delta$  = 77.00 ppm). All coupling constants (*J* values) are reported in hertz (Hz) and the following abbreviations are used to indicate multiplicity: s = singlet, d = doublet, t = triplet, dt = doublet of triplets, ddd = doublet of doublet of doublets, q = quartet, AA'XX' = AA'XX' spin system, and m = multiplet. HR-APCI mass spectra were obtained using a Thermo Scientific Exactive plus EMR. APCI-MS analysis was performed on Agilent technologies 6120 quadrupole LC/MS. HR-EI-MS were recorded on a Thermo Finnningham MAT95XP. GC-MS (EI/CI) were performed on an Agilent 5975C Triple Axis GC-MS. Fourier transform-infrared spectroscopy (FT-IR) was conducted using a Nicolet iS5 (Thermo Scientific) with an iD5 attenuated total reflection accessory. The abbreviations: w = weak, m = medium, s = strong and vs = very strong are used to denote relative absorbance intensities. Elemental compositions of carbon, hydrogen and sulfur atoms were measured using a Flash 2000 Organic Elemental Analyser (Thermo Scientific). Slow additions were performed using a Watsons-Marlow 205S peristaltic pump.

### Materials

All reactions were carried out under an argon or nitrogen atmosphere using standard Schlenk techniques. Anhydrous THF was freshly distilled over sodium/benzophenone. All other anhydrous solvents and reagents were purchased from Apollo Scientific, Sigma-Aldrich, Fisher Scientific, Alfa Aesar or

Acros and used as received. Deoxygenated solvents were prepared either by purging with argon or nitrogen. Column chromatography was performed using silica gel (60 Å, 230–400 mesh). Petroleum ether refers to the fraction obtained at 40–60 °C.

**Synthesis of 1,4-bis(bromomethyl)-2,5-bis(octyl)benzene (9).** Compound **8** (53.0 g, 175 mmol) and paraformaldehyde (21.0 g, 701 mmol) were dissolved in 33 wt% HBr(acetic acid) (123 mL) and heated under reflux for 5 days. The reaction was cooled to RT and the suspension poured onto ice. The precipitate was isolated by filtration and washed with water. The dark brown residue was dissolved in chloroform (500 mL) and the organic layer washed with 2 M NaHCO<sub>3</sub>(aq) (3 × 250 mL). The organic layer was dried over MgSO<sub>4</sub>, filtered and the solvent removed *in vacuo* to reveal a dark brown solid. The residue was recrystallised from ethanol to reveal colourless crystals (33.8 g, 40%). <sup>1</sup>H NMR, (CDCl<sub>3</sub>, 400 MHz):  $\delta$  7.14 (2H, s, ArH), 4.49 (4H, s, ArCH<sub>2</sub>Br), 2.66 (4H, t, *J* = 7.9 Hz, ArCH<sub>2</sub>CH<sub>2</sub>), 1.69–1.58 (4H, m, ArCH<sub>2</sub>CH<sub>2</sub>), 1.46–1.22 (20H, m, CH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>CH<sub>3</sub>), 0.89 (6H, t, *J* = 6.9 Hz, CH<sub>2</sub>CH<sub>3</sub>). <sup>13</sup>C NMR, (CDCl<sub>3</sub>, 126 MHz):  $\delta$  139.68, 135.88, 131.75, 31.86, 31.76, 31.31, 30.83, 29.71, 29.44, 29.24, 22.58, 14.11. MS (EI, M<sup>+</sup>): calc. for [C<sub>24</sub>H<sub>40</sub>Br<sub>2</sub>]<sup>+</sup>: *m/z* 488, found *m/z* 488.

**Synthesis of 1,4-bis(thiolatomethyl)-2,5-bis(octyl)benzene (10).** Compound **9** (33.0 g, 67.6 mmol) and thiourea (12.3 g, 162 mmol) were dissolved in deoxygenated THF (700 mL) and heated under reflux for 5 hours. The suspension was cooled to RT and the solvent removed *in vacuo* to reveal a white solid. Deoxygenated water (700 mL) and KOH (11.37 g, 203 mmol) were added and heated under reflux for 5 hours. The reaction was cooled to RT, neutralised with 50% H<sub>2</sub>SO<sub>4</sub>(aq) (v/v) and extracted with DCM (3 × 300 mL). The organic layers were combined, dried over MgSO<sub>4</sub>, filtered and the solvent removed *in vacuo* to reveal a yellow solid. The product was dissolved in CHCl<sub>3</sub> and precipitated into MeOH. The precipitate was isolated by filtration, washed with MeOH and dried under vacuum to reveal a fine white powder (16.1 g, 60%). <sup>1</sup>H NMR, (CDCl<sub>3</sub>, 500 MHz):  $\delta$  7.05 (2H, s, ArH), 3.71 (4H, d, *J* = 7.1 Hz, ArCH<sub>2</sub>SH), 2.62 (4H, t, *J* = 7.9 Hz, ArCH<sub>2</sub>CH<sub>2</sub>), 1.67 (2H, t, *J* = 7.1 Hz CH<sub>2</sub>SH), 1.65–1.56 (4H, m, ArCH<sub>2</sub>CH<sub>2</sub>), 1.45–1.22 (20H, m, CH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>CH<sub>3</sub>), 0.89 (6H, t, *J* = 7.0 Hz, CH<sub>2</sub>CH<sub>3</sub>). <sup>13</sup>C NMR, (CDCl<sub>3</sub>, 126 MHz):  $\delta$  138.29, 137.64, 130.31, 32.13, 31.88, 31.32, 29.81, 29.49, 29.28, 25.95, 22.67, 14.11. MS (APCI, M<sup>−</sup>): calc. for [C<sub>24</sub>H<sub>42</sub>S<sub>2</sub> − 1H]<sup>−</sup>: *m/z* 394, found *m/z* 394; calc. for [C<sub>24</sub>H<sub>42</sub>S<sub>2</sub> − 1SH]<sup>−</sup>: *m/z* 361, found; *m/z* 361.

**Synthesis of 5,8-dioctyl-2,11-dithia[3.3]paracyclophane (12).** Compound **11** (8.72 g, 51.2 mmol) and compound **9** (25.0 g, 51.2 mmol) were dissolved in deoxygenated toluene (1000 mL). This solution was added dropwise to KOH (8.62 g, 154 mmol) in deoxygenated ethanol (2500 mL), over 72 hours at RT. After a further 2 hours the solvent was removed *in vacuo* and the residue dissolved in diethyl ether (500 mL). Water (500 mL) was added and the solution neutralised with 6 M HCl<sub>(aq)</sub>. The organic layer was further washed with water (2 × 500 mL), dried over MgSO<sub>4</sub>, filtered and the solvent removed *in vacuo* to reveal an orange oil. The residue was purified by column

chromatography (DCM: petroleum ether, 10:90 (v/v)) yielding a colourless oil (10.9 g, 43%).  $^1\text{H}$  NMR, ( $\text{CDCl}_3$ , 500 MHz):  $\delta$  6.96 (2H, AA'XX',  $J_{app}$  = 7.9, 1.7 Hz, ArH), 6.86 (2H, AA'XX',  $J_{app}$  = 7.9, 1.7 Hz, ArH), 6.64 (2H, s, ArH), 3.92 (2H, d,  $J$  = 14.7 Hz,  $\text{ArCH}_2\text{S}$ ), 3.83 (2H, d,  $J$  = 15.2 Hz,  $\text{ArCH}_2\text{S}$ ), 3.77 (2H, d,  $J$  = 15.2 Hz,  $\text{ArCH}_2\text{S}$ ), 3.62 (2H, d,  $J$  = 14.7 Hz,  $\text{ArCH}_2\text{S}$ ), 2.71 (2H, ddd,  $J$  = 14.7, 8.8, 6.0 Hz,  $\text{ArCH}_2\text{CH}_2$ ), 2.42 (2H, ddd,  $J$  = 14.7, 8.8, 6.0 Hz,  $\text{ArCH}_2\text{CH}_2$ ), 1.55–1.22 (24H, m,  $\text{CH}_2(\text{CH}_2)_6\text{CH}_3$ ), 0.90 (6H, t,  $J$  = 6.7 Hz,  $\text{CH}_2\text{CH}_3$ ).  $^{13}\text{C}$  NMR, ( $\text{CDCl}_3$ , 101 MHz):  $\delta$  137.64, 134.96, 132.94, 131.65, 129.28, 127.72, 37.72, 34.68, 32.78, 31.86, 30.56, 29.78, 29.52, 29.27, 22.65, 14.10.
