Vinyl monomers bearing a sulfonyl-(trifluoromethane sulfonyl) imide group: synthesis and polymerization using nitroxide-mediated polymerization†

Trang N. T. Phan,^{*a} Adèle Ferrand,^a Hien The Ho,^a Livie Liénafa,^a Marion Rollet,^a Sébastien Maria,^a Renaud Bouchet^b and Didier Gigmes^a

A series of water-soluble styrene and propyl (meth)acrylate based monomers bearing a sulfonyl(trifluoromethane sulfonyl) imide (STFSI) group was prepared. These monomers were synthesized in good yield from the corresponding chloride sulfonyl monomer and trifluoromethanesulfonamide. Their chemical structures were further confirmed by HR-MS and NMR spectroscopy. Nitroxide-mediated polymerization of the prepared monomers was then performed in aqueous solution at 100 °C, 90 °C and 75 °C for acrylate, styrene and methacrylate derivatives, respectively. Controlled polymerization was successfully achieved as illustrated by the linearity of $\ln([M]_0/[M])$ vs. $t^{2/3}$, the molar mass increase with conversion and the relatively low dispersity values for the resulting homopolymers. Compared to their neutral analogous polymers, the prepared anionic homopolymers exhibited a higher glass-transition temperature. This phenomenon was attributed to the electrostatic interactions between STFSI side groups along the polymer backbone.

Introduction

The bis(trifluoromethane sulfonyl) imide anion (TFSI or $(CF_3SO_2)_2N^-$) can be used in different applications depending on the nature of the associated cation, *i.e.* metallic or organic. When the TFSI anion is associated with a metal such as lithium, the blend of the corresponding salt with a polymer matrix was largely used as a solid or gel electrolyte for lithium-polymer batteries.^{1–4} Moreover, the association of this anion with cations such as imidazolium, pyrrolidonium, and pyridinium attached to a polymer backbone gave rise to a highly interesting family of polymeric ionic liquids (PILs).^{5,6} On the other hand, the neutral derivatives of TFSI have also been used in synthetic organic chemistry. For instance, $(CF_3SO_2)_2N-H$ is considered as a strong Brønsted acid and applied as a catalyst for organic reactions,^{7,8} while the *N*-fluoro derivative $(CF_3SO_2)_2N-F$ is a powerful reagent for electrophilic fluorination.^{9,10} The derivatives of TFSI have also been used as proton-

exchange membranes for fuel-cell application.^{11,12} Interest in the TFSI salt and its derivatives is mainly due to their properties induced by the presence of the CF_3SO_2 group.¹³ Indeed, the strong electron-withdrawing effect of this group enhances the acidity of the hydrogen in $(CF_3SO_2)_2N-H$ and ensures a large delocalization of the negative charge. For these reasons, $(CF_3SO_2)_2N^+M^+$ exhibits a high ionic conductivity and good resistance to oxidation.

In the field of solid polymer electrolytes (SPEs) designed for lithium batteries, many polymer/lithium salt systems have been considered. However, to date the most widely studied and used system consists of a mixture of LiTFSI dissolved in an aprotic polymer matrix of poly(ethylene oxide) (PEO). In such binary salt-polymer systems, the ionic conductivity could be high above the melting temperature of PEO but the Li^+ transference number, that gives the proportion of the current carried by Li^+ ions, remains very low ($t^+ < 0.2$),¹⁴ leading under current to the formation of an ionic concentration gradient that limits substantially the power performances. To avoid this problem, the anions were covalently attached to the polymer backbones to form single-ion conductor copolymers with a lithium transference number close to unity.^{15,16} However, these solid polymer electrolytes (SPEs) exhibit a low conductivity mostly owing to the low level of ionic dissociation of carboxylates¹⁵ or borates.¹⁶ Recently, we have developed a novel family of single-ion electrolytes (SIEL) based on BAB triblock

copolymers having a PEO middle block and anionic polymers based on styrene and methacrylate derivatives bearing the lithium sulfonyl(trifluoromethane sulfonyl) imide group as outer blocks.^{17,18} The SIEL materials containing lithium poly(styrene sulfonyl(trifluoromethane sulfonyl) imide) (denoted as PSSTFSILi) have shown outstanding performances in terms of conductivity ($1.3 \times 10^{-5} \text{ S cm}^{-1}$ at 60 °C), transport number ($t^+ > 0.85$), mechanical properties and electrochemical stability window.¹⁷ These remarkable properties build on the combination of soft PEO-rich phases that enable the conduction of Li^+ with rigid PSSTFSILi phases that provide mechanical strength and act as a reservoir of cations.

The use of block copolymers as SPEs to combine in the same material the two antagonistic properties (mechanical and conductivity) was firstly proposed by Sadoway *et al.*¹⁹ Since this study, interest in block copolymers as SPEs for lithium batteries has continuously grown. Block copolymers can be prepared by different methods, but the living/controlled polymerization is the only way, which allows the synthesis of block copolymers with a well-defined structure. The development of reversible-deactivation radical polymerization (RDRP) techniques in the past two decades has largely promoted the synthesis of block copolymers. Furthermore, RDRP is more tolerant to protic functional monomers than anionic or group transfer polymerization techniques, and can be run in many conventional solvents over a wide range of temperatures.^{20–24}

Taking advantage of the charge delocalization character of STFSI and the very interesting electrolytes obtained with a monomer bearing STFSI anion, we were encouraged to develop new monomer structures containing a STFSI side group, namely methacrylate and acrylate based monomers. Prior to performing the preparation of block copolymers devoted to SPEs for lithium batteries, we first investigated the aqueous-polymerization of three monomer derivatives of styrene, methacrylate and acrylate (Scheme 1) using the Nitroxide-Mediated Polymerization (NMP) technique. This investigation is crucial to ensure that the polymerization reaction is well controlled and produces well-defined water-soluble polymers.

Scheme 1 Chemical formulae of nitroxide (SG1), alkoxyamine (MAMA-SG1) and vinyl monomers bearing sulfonyl(trifluoromethane sulfonyl) imide.

All aqueous polymerizations were carried out using an SG1-based alkoxyamine bearing a carboxylic acid function (so-called MAMA-SG1 or BlocBuilder MA, Scheme 1). In its basic form, the carboxylate function confers water solubility to the alkoxyamine and thus allows various water-soluble monomers to be polymerized by NMP in homogeneous aqueous solution.

It is well known now that the NMP of methacrylate monomers using MAMA-SG1 alkoxyamine can be performed in a controlled manner by adding a small amount of co-monomer such as styrene,^{25,26} sodium 4-styrenesulfonate,^{27,28} acrylonitrile,^{29,30} *N,N*-dimethylacrylamide³¹ or vinylbenzyl carbazole.³² In the present work, potassium methacrylate-STFSI was copolymerized with potassium styrene-STFSI as a comonomer. To illustrate the features of a controlled polymerization process, kinetic studies were performed and the molar masses of the collected samples were analyzed by size exclusion chromatography with DMF/LiBr as the eluent. The thermodynamic behavior of the prepared water-soluble polymers was also characterized by using differential scanning calorimetry (DSC).

Experimental section

Materials

Sodium 4-styrenesulfonate (SSNa, >90%), 3-sulfopropyl methacrylate potassium salt (MASPK, 98%), 3-sulfopropyl acrylate potassium salt (ASPK, >99%), oxalyl chloride (>99%), triethylamine (TEA, >99%), anhydrous acetonitrile (ACN) and anhydrous *N,N*-dimethylformamide (DMF) were purchased from Aldrich. Trifluoromethanesulfonamide (TFSA) was received from TCI Europe. SG1 (85%) and alkoxyamine based on SG1 derived from methacrylic acid (MAMA-SG1, >99%, trade name BlocBuilder MA) were kindly supplied by Arkema. All the above commercial chemicals were used as received. Sodium MAMA-SG1 was obtained after the deprotonation of the MAMA-SG1 alkoxyamine with sodium hydroxide, as described previously.³³ All solvents and other reagents were synthesis grade and used without further purification.

Analytical techniques

¹H, ¹³C and ¹⁹F NMR spectra were recorded on a Bruker Advance 400 MHz spectrometer. Monomer conversion was determined by ¹H NMR analysis using DMSO-d₆ as the solvent.

High-resolution mass spectroscopy (HR-MS) experiments were performed in the negative ion mode on a time-of-flight mass spectrometer (Synapt-G2 HDMS, Waters) equipped with a pneumatically assisted electrospray ion source. Samples were analyzed with the following conditions: capillary voltage 2.28 kV, cone voltage 10 V, and desolvation gas (nitrogen) flow rate 100 L h⁻¹. Poly(ethylene glycol) oligomers with *m/z* 325.1868 and *m/z* 369.2130 were used for the calibration as internal references.

Differential scanning calorimetry (DSC) was carried out on a TA DSC Q20 using a heat/cool/heat cycle from -90 °C to 250 °C. The heating and cooling rates were 10 °C min⁻¹. The

glass-transition temperature, T_g , was determined from the second heating cycle of the DSC thermograms.

Size exclusion chromatography (SEC) experiments were performed on a Varian PL-GPC 120 apparatus, which was composed of a PL-AS-MT autosampler, an Agilent 1100 series pump, a degasser, an injection valve, a column oven and a refractive index (RI) detector. The following columns were used: one pre-column and two PL Resipore columns (300 mm \times 7.8 mm). The injection loop, the columns and the RI detector were in the same oven thermostated at 70 °C. The eluent was a solution of 0.1 M LiBr in *N,N*-dimethylformamide filtered through a 0.45 μ m nylon membrane and the flow rate was fixed at 0.7 mL min⁻¹. The samples were prepared in a mixture of eluent and toluene (0.25 vol%) as the flowmarker, filtered through a 0.2 μ m nylon filter (Interchim) and placed in an autosampler preheated at 50 °C. The sample concentration was 0.25 wt%. Calibration curves were established with either polystyrene (PS) standards or poly(methyl methacrylate) (PMMA) standards, both purchased from Agilent.

Synthesis of potassium 4-styrenesulfonyl(trifluoromethane sulfonyl) imide, SSTFSIK

SSTFSIK was prepared according to the literature.³⁴ The monomer was obtained as a white powder in 50% yield.

¹H NMR (400 MHz, DMSO-*d*₆, δ ppm): 5.38 (CH₂=CH-, d, 1H), 5.95 (CH₂=CH-, d, 1H), 6.77 (CH₂=CH-, dd, 1H), 7.64 (C₆H₄-, dd, 4H). ¹⁹F NMR (DMSO-*d*₆, δ ppm): -77.81. ⁷Li NMR (DMSO-*d*₆, δ ppm): -1.00. ¹³C NMR (DMSO-*d*₆, δ ppm): 116.78 (CH₂=CH-), 118.48 and 121.70 (-CF₃), 126.07-126.61 (-CH₂ aromatic), 135.74 (CH₂=CH-), 139.77 and 144.35 (-CH aromatic).

HR-MS (C₉H₇NO₄S₂F₃K): $m/z = [M - K^+]_{\text{found}} = 313.9775$ g mol⁻¹, $[M - K^+]_{\text{cal}} = 313.9769$ g mol⁻¹.

Synthesis of potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl acrylate, ASTFSIK

Oxalyl chloride (2.40 mL, 28.3 mmol) and *N,N*-dimethylformamide (0.50 mL) were added dropwise under argon to a three-necked round bottom flask containing anhydrous acetonitrile (30.0 mL) at 0 °C. The mixture was stirred for 1 h at room temperature. Then, the solution was chilled down to 0 °C and potassium 3-sulfopropyl acrylate (5.00 g, 21.6 mmol) was added into the solution under argon. The resulting solution was continuously stirred at 0 °C for 3 h and 2 h more at room temperature to achieve the formation of 3-(chlorosulfonyl) propyl acrylate. Then a solution of trifluoromethanesulfonamide (2.66 g, 1.79 \times 10⁻² mol) and triethylamine (6.80 mL, 4.91 \times 10⁻² mol) dissolved in acetonitrile (10.0 mL) at 0 °C under argon was added to the 3-(chlorosulfonyl) propyl acrylate solution. The reaction mixture was allowed to react at 0 °C for 2 h and then at room temperature for 16 h under argon. The reaction mixture was filtered off and the recovered white solid was washed with acetonitrile. The filtrate was concentrated under vacuum then dissolved in dichloromethane and washed successively with a saturated NaHCO₃ solution, a solution of 1 M chloride acid and a saturated NaCl solution, dried

over MgSO₄, filtered and evaporated under reduced pressure. The product was obtained as amber oil (5.20 g, 68% yield). To the cold solution of triethylammonium-3-sulfonyl(trifluoromethane sulfonyl) imide propyl acrylate (3.00 g, 7.04 \times 10⁻³ mol) in 30 mL of acetonitrile (30.0 mL) was slowly added potassium carbonate (1.94 g, 1.41 \times 10⁻² mol). After the complete addition of K₂CO₃, the mixture reaction was allowed to react at 0 °C to room temperature for 4 hours. The solution was then filtered and the filtrate was concentrated under vacuum. The yellowish solid was recrystallized from hot dichloromethane. The mixture solution was then kept at -20 °C for 3 h. The obtained solid was washed with cold *n*-pentane and dried under vacuum to obtain a white solid (60% yield).

¹H NMR (400 MHz, DMSO-*d*₆, δ ppm): 6.34 (CH₂=CH-, d, 1H), 6.18 (CH₂=CH-, dd, 1H), 5.95 (CH₂=CH-, d, 1H), 4.19 (-O-CH₂-, t, 2H), 3.05 (-CH₂-SO₂-, t, 2H), 2.01 (-CH₂-, m, 2H). ¹³C NMR (DMSO-*d*₆, δ ppm): 165.87 (C=O), 132.00 (CH₂=CH-), 128.71 (CH₂=CH-), 125.41-115.74 (-CF₃), 63.01 (-COOCH₂-), 51.72 (-CH₂SO₂-), 23.97 (-COOCH₂-). ¹⁹F NMR (DMSO-*d*₆, δ ppm): -77.54.

HR-MS (C₇H₉NO₆S₂F₃K): $m/z = [M - K^+]_{\text{found}} = 323.9832$ g mol⁻¹, $[M - K^+]_{\text{cal}} = 323.9829$ g mol⁻¹.

Synthesis of potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl methacrylate, MASTFSIK

A similar procedure to the synthesis of ASTFSIK was used to prepare MASTFSIK. In this case, 3-sulfopropyl methacrylate potassium salt was used instead of 3-sulfopropyl acrylate potassium salt. The product was obtained as a white powder (60% yield).

¹H NMR (400 MHz, DMSO-*d*₆, δ ppm): 6.04 (CH₂=C, s, 1H), 5.68 (CH₂=C, s, 1H), 4.17 (-O-CH₂-, t, 2H), 3.06 (-CH₂-SO₂-, t, 2H), 2.01 (-CH₂-, m, 2H), 1.88 (-CH₃-, s, 3H). ¹³C NMR (DMSO-*d*₆, δ ppm): 166.42 (C=O), 135.81 (CH₂=CH-), 125.75 (CH₂=CH-), 123.10-115.26 (-CF₃), 62.07 (-COOCH₂-), 51.25 (-CH₂SO₂-), 23.53 (-COOCH₂-), 17.94 (-CH₃). ¹⁹F NMR (DMSO-*d*₆, δ ppm): -77.53.

HR-MS (C₈H₁₁NO₆S₂F₃): $m/z = [M - K^+]_{\text{found}} = 337.9985$ g mol⁻¹, $[M - K^+]_{\text{cal}} = 337.9985$ g mol⁻¹.

General procedure for the NMP of different anionic monomers

Anionic monomer, SG1 and distilled water were placed in a three-neck flask equipped with a reflux condenser and a magnetic stir bar. The mixture was purged for 30 min with argon at 40 °C to remove oxygen. In parallel, the water-soluble alkoxyamine, sodium MAMA-SG1 was dissolved in 2 mL of distilled water and degassed by bubbling argon for 20 min at room temperature. This alkoxyamine solution was transferred, *via* a cannula, to the degassed monomer solution. The mixture was heated to appropriate temperature according to the monomer nature. The [SG1]/[MAMA-SG1] ratio was between 5% and 10%, and the monomer concentration in the polymerization mixture was varied from 10 to 30 wt%. For kinetic studies, samples were collected from the reaction mixture at given time intervals. Conversion and molecular weights were determined by ¹H NMR spectroscopy and LiBr-DMF SEC, respectively.

Table 1 Experimental conditions for the nitroxide-mediated polymerization of different anionic monomers in aqueous solution

Entry	Monomer	T (°C)	m_{monomer} (g)	$\text{mol}_{\text{MAMA-SG1}}$ (mmol)	r^a (%)	[Monomer] wt% in water	Target M_n^b at full conversion (g mol^{-1})

2	MASTFSIK/SSTFSIK	75	0.81/0.19	47.2	10	20	30 000
3	ASTFSIK	100	1.3	47.2	7	30	30 000

^a $r = 100 \times [\text{SG1}]_0 / [\text{MAMA-SG1}]_0$. ^b Theoretical number-average molar mass, calculated according to $M_n = \text{MM}(\text{MAMA-SG1}) + \text{conversion} \times \text{initial weight of the monomer} / \text{initial mol number of MAMA-SG1}$, with conversion = 1 and molar mass of the initiator, $\text{MM}(\text{MAMA-SG1}) = 381 \text{ g mol}^{-1}$.

Table 1 summarizes the experimental conditions of the performed polymerization experiments.

Because of the poor solubility of SSTFSIK in water, this monomer was converted to the lithium salt and then polymerized in diluted solution at 10 wt%. For the polymerizations of acrylate-STFSIK and methacrylate-STFSIK, targeted molar masses (M_n) of anionic polymers at 100% conversion were targeted at $30\,000 \text{ g mol}^{-1}$, while that of styrene-STFSiLi was targeted at $40\,000 \text{ g mol}^{-1}$.

Results and discussion

Monomers design and synthesis

Three vinyl monomers based on styrene and methacrylate and acrylate monomers functionalized with a sulfonyl(trifluoromethane sulfonyl) imide group were prepared (Scheme 1). These monomers were selected with the aim to elaborate thereafter single-ion block copolymer electrolytes for lithium batteries. By varying the composition and the structure of the investigated block copolymers, our motivation was to tune their corresponding electrolyte properties such as thermal stability, chain mobility and conductivity performance.

The synthesis of SSTFSIK was first described by Armand³⁵ and readapted by other authors.^{8,34,36} 4-Vinylbenzenesulfonyl chloride, as an intermediate compound, was synthesized and reacted *in situ* with trifluoromethanesulfonamide in the presence of triethylamine to yield a viscous liquid. Cation exchange of the liquid with an excess of LiOH in methanol yields the lithium styrene-STFSI derivative. A high purity product can be obtained after washing the solid with *n*-pentane and cold dichloromethane. The formation of the lithium styrene-STFSI monomer was proven by ¹⁹F NMR with a singlet at -77.81 ppm , to be compared with the signal of the starting

compound trifluoromethanesulfonamide $\text{CF}_3\text{SO}_2\text{NH}_2$, which is at -79.32 ppm . ¹H, ⁷Li and ¹³C NMR were also used to characterize the structure of SSTFSiLi (Fig. S1–S3†).

The synthetic route for potassium methacrylate-STFSI and potassium acrylate-STFSI is depicted in Scheme 2. The corresponding 3-sulfo-propyl (meth)acrylate potassium salts are commercially available and were converted into sulfonyl chloride derivatives upon reaction with oxalyl chloride in the presence of DMF as the catalyst (Vilsmeier–Haack reaction). The intermediate chloride products were then reacted with trifluoromethanesulfonamide in the presence of an excess of triethylamine. The use of an excess of triethylamine ensures the obtention of all monomers in their triethylammonium salt form avoiding the obtention of a mixture of salt and acid forms. The last step consisted of an ionic exchange of the triethylammonium ion with the potassium ion. This step was performed by using K_2CO_3 instead of Li_2CO_3 or LiOH used in the synthesis of SSTFSiLi. Indeed, the basicity of the latter is too strong and may induce the hydrolysis of the (meth)acrylate ester bond. The global yield was typically close to 60%. Each compound was characterized by ¹H, ¹⁹F, ¹³C NMR and HRMS. The ¹⁹F NMR spectra of the purified monomers (Fig. S4†) showed a shift of the characteristic signal of the trifluoromethyl group before and after the reaction. The combination of this result and those of other analyses indicates the formation of the right products. ¹H and ¹³C NMR spectra are shown in the ESI (Fig. S5–S8†).

Aqueous NMP of different anionic monomers bearing a sulfonyl(trifluoromethane sulfonyl) imide group

The NMP of hydrophilic monomers has been very seldom performed in aqueous solution. We found only a few examples available in the literature^{28,30,33,37–40} and among them only five articles^{28,33,38–40} that describe the use of SG1 nitroxide. In

Scheme 2 Synthetic route for the preparation of potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl methacrylate (MASTFSIK) and potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl acrylate (ASTFSIK).

Table 2 Characteristics of the obtained polymers

Polymer	Target M_n^a at full conversion (g mol^{-1})	Polymerization time (min)	Total conversion (NMR) (%)	M_n^b (th) (g mol^{-1})	M_n (SEC) (g mol^{-1})	Dispersity

M_n , the number-average molar mass, calculated according to the equation $M_n = \text{MM}(\text{MAMA-SG1}) + \text{conversion} \times \text{initial weight of monomer} / \text{initial mol number of MAMA-SG1}$, $\text{MM}(\text{MAMA-SG1}) = 381 \text{ g mol}^{-1}$. ^a Values calculated with conversion of 100%. ^b Values calculated with conversion determined by ¹H NMR.

these studies, the considered monomers were either neutral monomers (acrylamide, *N,N*-dimethylacrylamide, poly(ethylene glycol) methyl ether methacrylate)^{33,38,39} or anionic monomers (sodium 4-styrenesulfonate, methacrylic acid).^{28,33,40} Anionic monomers with a sulfonyl(trifluoromethane sulfonyl) imide group have never been investigated in aqueous medium using RDRP and we barely know if this kind of functional monomer could be polymerized in a controlled manner. Then the first aim of this work was to follow the polymerization kinetics and to determine the most appropriate conditions for achieving polymerization with all the controlled features. All characteristics of the obtained polymers are summarized in Table 2.

Aqueous NMP of lithium 4-styrenesulfonyl(trifluoromethane sulfonyl) imide

Conventional radical polymerization of potassium or sodium 4-styrene sulfonyl(trifluoromethane sulfonyl) imide using $\text{K}_2\text{S}_2\text{O}_8$ as the initiator^{34,36} as well as those using Reversible Addition–Fragmentation chain Transfer (RAFT) polymerization in DMF solution^{41,42} were already reported. Cloutet *et al.* have recently demonstrated that SSTFSIK could be polymerized with DMF as the solvent by the RAFT method to yield a homopolymer with low dispersity ($D = 1.02$) at high monomer conversion (98%) for a polymerization time of 14 hours. In the present study, lithium styrene-STFSI was polymerized at 90 °C in dilute aqueous solution (10 wt% of monomer) using sodium MAMA-SG1 as the initiator in the presence of 5 mol% of free SG1 nitroxide compared to alkoxyamine. It was demonstrated that the addition of free SG1 allows one to obtain better control of hydrophilic monomers polymerization in terms of kinetic evolution and dispersities.³³ To support that the NMP of Li styrene-STFSI was well-controlled, a complete kinetic study for a target M_n of 40 000 g mol^{-1} at full conversion was performed. Fig. 1 gives the kinetic plots of $\ln([M]_0/[M])$ vs. reaction time (t and $t^{2/3}$). The linearity of the kinetic plots when plotted as $\ln([M]_0/[M])$ vs. $t^{2/3}$ rather than t lies in the radical persistent effect. According to Fischer's⁴³ and Fukuda's⁴⁴ work, the minimization of the irreversible termination in the NMP process is governed by the persistent radical effect. Considering an alkoxyamine compound (RY) that decomposes into a transient radical (R[•]) and a persistent radical (Y[•]), this persistent radical effect leads to two unusual rate laws for R[•] and Y[•] during the intermediate regimes: $[Y^{\bullet}] = \left(\frac{3k_t k_d^2 [RY]_0^2}{k_c^2}\right)^{1/3} t^{1/3}$ and

Fig. 1 Evolution of $\ln([M]_0/[M])$ versus reaction time (t and $t^{2/3}$) for the NMP of lithium styrene-STFSI in aqueous solution at 90 °C using sodium MAMA-SG1 as the initiator in the presence of 5 mol% of free SG1.

$[R^{\bullet}] = \left(\frac{k_d [RY]_0}{3k_x k_c}\right)^{1/3} t^{-1/3}$, where k_d , k_c and k_t are the rate constants of the decomposition reaction, the combination reaction of RY and the termination reaction between two R[•], respectively. Consequently, the kinetic law of monomer concentration is thus given by $\ln\left(\frac{[M]_0}{[M]}\right) = \frac{3k_p}{2} \left(\frac{k_d [RY]_0}{3k_t k_c}\right)^{1/3} t^{2/3}$; hence, the plots of $\ln([M]_0/[M])$ versus time should show a downward curvature while the plots of $\ln([M]_0/[M])$ versus $t^{2/3}$ should be linear. This persistent radical effect was experimentally validated in the NMP of styrene and acrylates by different groups.^{45–47} On the other hand, in the case of high propagation rate constant monomers, an initial excess of persistent radicals is added at the beginning of the polymerization process to slow down its rate and improve the polymerization control.^{33,48} Under these conditions, the concentration of the transient radicals reaches the stationary value $[R^{\bullet}]_{\text{stationary}} = K[RY]_0/[Y^{\bullet}]_0$ (with $K = k_d/k_c$) and the linear evolution of the polymerization index $\ln([M]_0/[M])$ with time is generally observed.^{49,50} However, since the self-

termination of the propagating radicals increases with the polymerization time and causes an additional Y^* amount, when this released nitroxide concentration $[Y^*]$ exceeds the initial one $[Y^*]_0$, the behavior of the system turns to that observed without the initial persistent species. Fischer *et al.*⁵⁰ theoretically demonstrated that if $[Y^*]_0 > (3[\ln(10)]K[RY]_0k_t/k_p)^{1/2}$, the polymerization index $\ln([M]_0/[M])$ varies linearly with time. On the contrary, if $[Y^*]_0 < (3K[RY]_0k_t/k_p)^{1/2}$, the initial presence of the persistent species has no influence, and the polymerization index $\ln([M]_0/[M])$ increases linearly with $t^{2/3}$.

Depending on the polymerization system, the propagation can take place in the first mode or could happen in both modes and in certain cases; the presence of the persistent species has no influence and the kinetics vary with time as $t^{2/3}$. There are relatively few experimental studies that have investigated the effect of free nitroxide concentration on the NMP. Becer *et al.*⁵¹ in a systematic kinetic screening have studied the influence of the concentration of free nitroxide SG1 (0–10 mol% with respect to the initiator) on the NMP of styrene and *tert*-butyl acrylate. They found no significant effect of the introduction of a slight excess of free nitroxide for the styrene polymerization; however, the polymerization rate of *tert*-butyl acrylate was reduced with the increasing SG1 concentration. For an initial concentration of SG1 introduced in the polymerization medium ≥ 1 mol% with respect to the initiator, the polymerization index $\ln([M]_0/[M])$ varies linearly with time for both monomers.

In our case, as no values of k_p and k_t are available in the literature for lithium styrene-STFSI and the two other monomers studied in the present work, it is difficult for us to estimate precisely if the initial SG1 concentration introduced in the polymerization medium was higher than $(3[\ln(10)]K[MAMA-SG1]_0k_t/k_p)^{1/2}$ or lower than $(3K[MAMA-SG1]_0k_t/k_p)^{1/2}$. For the NMP of lithium styrene-STFSI in the presence of 5 mol% of SG1 with respect to MAMA-SG1, we found a linear fit of $\ln([M]_0/[M])$ with $t^{2/3}$ rather than with time. This suggests that the initial concentration of SG1 used was not enough to suppress the persistent radical effect conditions due probably to the fast activation step in the polar medium. The similar phenomenon was also observed in the Atom Transfer Radical Polymerization (ATRP) system by Zhang *et al.*⁵² They demonstrated through a full kinetic analysis of the CuBr-mediated ATRP of methyl methacrylate that when $[Cu(II)]_0/[Cu(I)]_0 \leq 0.1$, the reaction kinetics fits quite well Fischer's equation with $\ln([M]_0/[M])$ as a function of $t^{2/3}$ and when $[Cu(II)]_0/[Cu(I)]_0 \geq 0.1$, the reaction kinetics fits quite well with $\ln([M]_0/[M])$ as a function of t . In this case, the addition of at least 10 mol% of Cu(II) in the initial mixture is needed to neglect the persistent radical effect.

To further characterize the control of the chain growth polymerization, evolution of the theoretical and experimental M_n values was plotted (Fig. 2a). The experimental M_n values increased linearly with monomer conversion and the molar mass distributions were narrow as attested by the dispersity values. However, the experimental M_n values evaluated from the SEC calibration curve established with polystyrene stan-

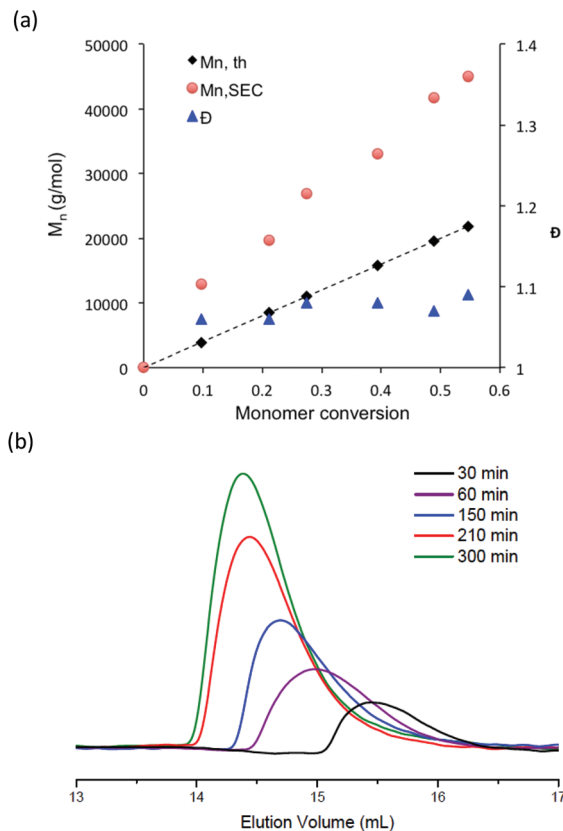

Fig. 2 (a) Evolution of theoretical and experimental M_n and dispersity with conversion; experimental M_n estimated by using the calibration curve established with polystyrene standards. (b) Size exclusion chromatograms (DMF solution with 0.1 mol L^{-1} of LiBr) for poly(lithium 4-styrene-STFSI) homopolymer at various polymerization times.

dards were considerably higher than the expected ones. According to the principle of the SEC technique, the determination of the polymer molecular weight is based on the hydrodynamic volume of the polymer in the mobile phase. DMF used for the SEC mobile phase is considered as a “poor” solvent for PS but as a “good” solvent for poly(styrene-STFSI), it means that PS is poorly solvated and poly(styrene-STFSI) is well solvated in DMF. Considering the two polymers with a similar length, the hydrodynamic volume of PS will be smaller than that of poly(styrene-STFSI). This explains why we obtained the experimental M_n values for poly(styrene-STFSI) which were higher than the expected values. The SEC traces (Fig. 2b) show the continuous shift to smaller retention volumes with the increasing reaction time and are all unimodal with no evidence of the presence of high molecular weight polymers that may be indicative of uncontrolled polymerization and/or termination reactions. These data show clearly the controlled nature of the aqueous NMP of lithium styrene-STFSI using MAMA-SG1 as the initiator. However, some tailing is observed at high elution volume of the SEC chromatograms, probably coming from the interactions between the polymer chains and stationary phase.

Aqueous NMP of potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl methacrylate

Apart from the synthesis of a specific nitroxide exclusively devoted to methacrylate monomers,⁵³ the NMP of methacrylate monomers using nitroxide agents is difficult to achieve due to a too high equilibrium constant for the propagation step and/or undesired side reaction.^{20,54,55} To favor the formation of stable chain-end alkoxyamine and obtain a controlled/living system, methacrylate monomers are usually copolymerized with a comonomer, which is well controlled by NMP. The NMP of hydrophilic methacrylate monomers was generally carried out in organic solvent solution such as dioxane, dimethylsulfoxide or ethanol. There is only one paper that describes the nitroxide-mediated copolymerization of hydrophilic methacrylate monomers in water solution.²⁸ In this study, the authors succeeded to control the SG1-mediated polymerization of methacrylic acid performed in water solution at 76 °C and in the presence of less than 10 mol% of sodium 4-styrenesulfonate. In the present work, potassium methacrylate-STFSI was copolymerized with potassium styrene-STFSI in water solution with a monomer content of 20 wt%, using sodium MAMA-SG1 as an alkoxyamine initiator and in the presence of 10 mol% of free-SG1 nitroxide. The initial molar fraction of potassium styrene-STFSI was chosen at 0.2 and polymerization reactions were performed at 65 °C and 75 °C. For the copolymerization performed at 65°, we observed polymerization kinetics to be extremely slow with a retardation period up to 80 min (Fig. S9†). During this period, neither of the two monomers was polymerized. From 80 min to 300 min, we observed nevertheless the linearity of $\ln([M]_0/[M])$ when plotted *versus* $t^{2/3}$, however, SEC chromatograms (not shown here) of these samples did not exhibit any shifts toward higher molar masses. When the polymerization was performed at 75 °C for a target M_n of 30 000 g mol⁻¹ at full conversion, we observed that the reaction was fast. Indeed, conversions close to 100% were reached within 100 min (Fig. 3a). $\ln([M]_0/[M])$ of individual monomers was also plotted *versus* $t^{2/3}$ with the aim to check the controlled character of the polymerization (Fig. 3b). As can be seen in Fig. 3b, $\ln([M]_0/[M])$ *versus* $t^{2/3}$ was almost linear for potassium styrene-STFSI and potassium methacrylate-STFSI at least until 70 min. However, at this time, the conversion of SSTFSI-K was quasi-complete (>92%) and about 60% for the overall monomer conversions. After the complete disappearance of the styrene monomer in the polymerization mixture, the control of methacrylate polymerization was lost. Indeed, to ensure good control of the methacrylate monomer the polymerization mixture must always contain at least 7–10 mol% of comonomer.^{25,56} Below 60% overall monomer conversions, the M_n increased linearly with monomer conversion (Fig. 4a) and dispersity values were low ($\mathcal{D} < 1.2$). Like for the polymerization of SSTFSI-Li discussed above, the experimental M_n values, derived from the calibration curve established with PMMA standards, were above the expected data. However, the difference between the experimental M_n values and the expected ones is now considerably reduced compared

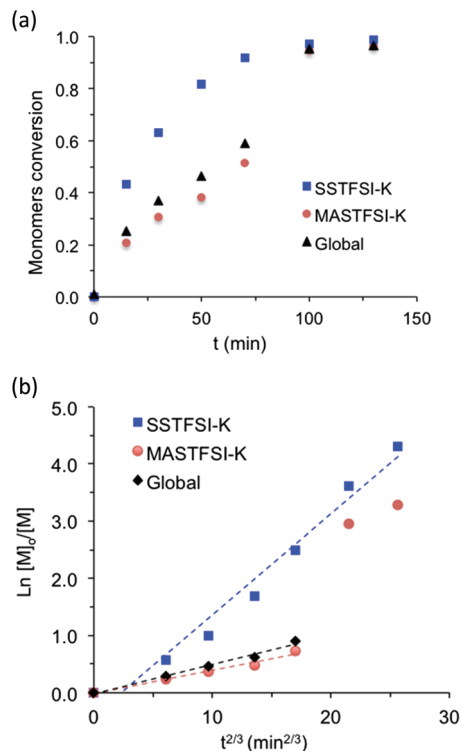

Fig. 3 Evolution of (a) monomer conversion vs. t and (b) $\ln([M]_0/[M])$ vs. $t^{2/3}$ for the nitroxide-mediated copolymerization of potassium methacrylate-STFSI and potassium styrene-STFSI in water solution at 75 °C using sodium MAMA-SG1 as the initiator in the presence of 10 mol% of free SG1.

to the case of poly(styrene-STFSI) since DMF is considered as a “theta” (quite good) solvent of PMMA. The controlled character of the polymerization was further attested by the shift of the SEC chromatograms with the polymerization time (Fig. 4b). The SEC peaks corresponding to the polymerization time of 100 min and 130 min were superimposed with the large distributions of molar masses indicating the loss of polymerization control.

From these results, it undoubtedly appeared that the SG1-mediated copolymerization of potassium methacrylate-STFSI and potassium styrene-STFSI under the employed conditions was fast and ill-controlled above 60% overall monomer conversion.

Aqueous NMP of potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl acrylate

In comparison with hydrophilic styrene or methacrylate monomers, hydrophilic acrylate monomers and anionic acrylate derivatives have been the subject of a limited number of studies. As far we are aware, there have been only a few reports of the polymerization of anionic acrylates by living radical polymerization in aqueous media and they were mainly from RAFT polymerization.^{57,58} In the present work, potassium 3-sulfonyl(trifluoromethane sulfonyl) imide propyl acrylate was polymerized at 100 °C in water solution using sodium

Fig. 4 (a) Evolution of theoretical and experimental M_n and dispersity with conversion; experimental M_n estimated by using the calibration curve established with PMMA standards. (b) Size exclusion chromatograms (DMF solution with 0.1 mol L^{-1} of LiBr) for the poly(SSTFSI-K-co-MASSTFSI-K) copolymer at various polymerization times.

MAMA-SG1 as sodium MAMA-SG1 alkoxyamine. The reaction temperature was chosen based on our previous work on the NMP of the cationic acrylate monomer.³³ Polymerization was performed with a target M_n of $30\,000 \text{ g mol}^{-1}$, a monomer concentration of 30 wt% in water and in the presence of 7 mol% of free SG1 to initiator. In all cases, the polymerization reactions proceeded smoothly with reaction kinetics following $\ln([M]_0/[M])$ as a function of $t^{2/3}$ (Fig. 5b). Monomer conversion was lower compared to styrene and methacrylate derivatives although the reaction temperature and monomer content were higher (Fig. 5a). The SEC chromatograms of the produced polymer shifted steadily to a lower elution volume with increasing monomer conversion (Fig. 6a). The evaluation of the molar masses from the calibration established with PMMA standards indicated low dispersity values ($\bar{D} < 1.2$) and molar masses increased linearly with conversion (Fig. 6b). However, the apparent M_n values are higher than the theoretical values based on conversion, as the polymer standard is not appropriate and also because of the difference of solvation between the polymer standard and the analyzed polymer in the mobile phase as well as the possible interactions between the polymer chain and the stationary phase.

Fig. 5 Evolution of (a) monomer conversion vs. t and (b) $\ln([M]_0/[M])$ vs. $t^{2/3}$ for the NMP of potassium propyl acrylate-STFSI in water solution at $100 \text{ }^\circ\text{C}$ using sodium MAMA-SG1 as the initiator in the presence of 7 mol% of free SG1.

Thermodynamic behavior of water-soluble polymers bearing a sulfonyl(trifluoromethane sulfonyl) imide group

The thermodynamic behavior of the prepared polymers was studied by differential scanning calorimetry (DSC). For this purpose, samples were heated between $40 \text{ }^\circ\text{C}$ and $250 \text{ }^\circ\text{C}$ for styrene and methacrylate based polymers and between $-90 \text{ }^\circ\text{C}$ and $150 \text{ }^\circ\text{C}$ for acrylate based polymers. DSC traces of these polymers are shown in Fig. S10 and S11.† We found that the T_g of the homopolymer lithium PSSTFSI was $172 \text{ }^\circ\text{C}$, which is in good agreement with those reported in the literature. For example, the lithium PSSTFSI synthesized by free-radical polymerization presents a T_g value of about $152 \text{ }^\circ\text{C}$,^{34,41} however Long *et al.* have noted that T_g varied significantly depending on the choice of the counterion; in particular, voluminous cations or divalent cations lead to polymer networks with a higher T_g .⁴¹ Recently, Hadziioannou *et al.* showed that PSSTFSIK samples obtained by RAFT polymerization exhibited also high T_g values which increased from $179 \text{ }^\circ\text{C}$ to $239 \text{ }^\circ\text{C}$ as the polymer molar masses varied from 6000 g mol^{-1} to $80\,000 \text{ g mol}^{-1}$.⁴² The poly(SSTFSIK-co-MASTFSIK) copolymer exhibits two T_g values at $132 \text{ }^\circ\text{C}$ and $174 \text{ }^\circ\text{C}$ with a high heat flow amplitude for the first T_g . The observation of two T_g values suggests that the copolymer is not random but rather a gradient copolymer with a rich part of methacrylate and a rich part of styrene. Thus, the first T_g was attributed to PMASTFSIK and the second, close to the T_g value observed for PSSTFSILi previously, to PSSTFSIK. As expected for the polyacrylate back-

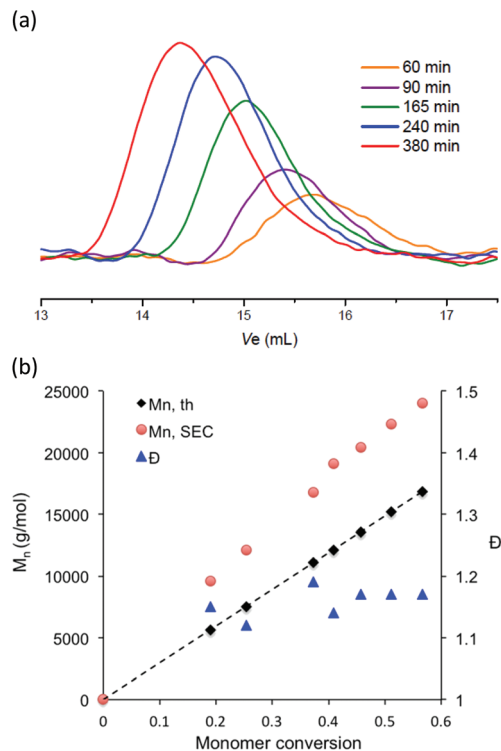

Fig. 6 (a) Size exclusion chromatograms (DMF solution with 0.1 mol L^{-1} of LiBr) for poly(ASTFSI-K) at various polymerization times. (b) Evolution of theoretical and experimental M_n and dispersity with conversion; experimental M_n estimated by using the calibration curve established with PMMA standards.

bone, the T_g value of the PASTFSIK homopolymer was much lower than those observed for styrene and methacrylate based polymers, which was 17°C . However, one can note that thermal transition took place on a very large temperature domain. By comparison with the corresponding polystyrene and poly(propyl (meth)acrylate), all the studied water-soluble polymers bearing a sulfonyl(trifluoromethane sulfonyl) imide group exhibit higher T_g values (50°C to 80°C) due to strong electrostatic interactions between the potassium or lithium STFSI groups. These anionic polymers with their interesting thermodynamic behavior will probably give rise to the good block copolymer electrolytes for lithium battery when they associate with a ionic conductor block.

Conclusion

Besides higher performance batteries, safer battery technologies are the next major issues in the battery industry. For this purpose, we have recently developed single-ion solid block copolymer electrolytes.¹⁷ In order to gain more information on such kinds of electrolytes and improve their performances, other anionic monomers bearing a sulfonyl(trifluoromethane sulfonyl) imide group, namely potassium propylmethacrylate-STFSI and potassium propylacrylate-STFSI, were successfully synthesized with good yield (60%) and fully characterized by

HR-MS and ^1H , ^{13}C and ^{19}F NMR spectroscopy. Then, nitroxide-mediated polymerization of these hydrophilic monomers bearing an STFSI anion (SSTFSILi, MASTFSIK and ASTFSIK) in homogeneous aqueous medium was achieved using a SG1-based alkoxyamine bearing a carboxylic acid group. These polymerizations present the typical features of controlled polymerization, such as the linearity of $\ln([M]_0/[M])$ as a function of $t^{2/3}$ up to high conversions, a linear increase of the molecular weight with conversion and low dispersity values ($D < 1.2$). In the case of the methacrylate-based monomer, 20 mol% of the styrene based monomer was required to reach good polymerization control. The NMP in water yields well-defined polymers with methacrylate, styrene and acrylate based water-soluble monomers at 75 , 90 , and 100°C , respectively. The obtained protocol will be usefully applied in the preparation of block copolymers devoted to SPE for lithium batteries. Furthermore, these anionic polymers show a higher glass transition temperature compared to their neutral analogous polymers. The thermodynamic behavior of these anionic polymers once associated with the PEO block should lead to interesting solid electrolytes for lithium batteries.

Acknowledgements

The present work was undertaken within the French ANR program under the contract COPOLIBAT 2, no. ANR-13-PRGE-0002-02. The authors wish to thank Arkema for kindly providing the MAMA-SG1 initiator and the nitroxide SG1. They are grateful to Jean-Pierre Bonnet for his help in MASTFSIK synthesis.
