Novel bis- and tris-cyclometalated iridium(III) complexes bearing a benzoyl group on each fluorinated 2-phenylpyridinate ligand aimed at development of blue phosphorescent materials for OLED†

Naoki Okamura, a Taiyo Nakamura, a Shigeyuki Yagi, *a Takeshi Maeda, a Hiroyuki Nakazumi, a Hideki Fujiwara b and Shiro Koseki b

Novel bis- and tris-cyclometalated iridium(III) complexes bearing a benzoyl group on each fluorinated 2-phenylpyridinate ligand were developed, aimed at the development of blue phosphorescent materials for organic light-emitting diodes (OLED). When acetylacetonate (acac) was employed as an ancillary ligand, the emission wavelength ($\lambda_{PL}$) of the 5'-benzoylated bis-cyclometalated complex was blue-shifted up to 479 nm (in dichloromethane at rt, emitting bluish green) in combination with fluorine substituents. Ancillary ligand replacement in the 2-(5-benzoyl-4,6-difluorophenyl)pyridinate-based bis-cyclometalated complex from acac to picolinate gave rise to a further blue shift of $\lambda_{PL}$ to 464 nm, and sky-blue emission was observed. The 2-(5-benzoyl-4,6-difluorophenyl)pyridinate-based homoletic triscyclometalated complex exhibited a more blue-shifted $\lambda_{PL}$ at 463 nm than any other bis- and tris-cyclometalated complexes developed here, emitting sky blue with a photoluminescence quantum yield of 0.90 (in dichloromethane at rt). Using this sky-blue phosphorescent tris-cyclometalated complex as an emitting dopant, a poly(9-vinylcarbazole)-based OLED was fabricated, and excellent blue emission with a Commission Internationale de L’Eclairage (CIE) chromaticity coordinate of (0.16, 0.28) was observed, where an external quantum efficiency ($\eta_{ext}$) of 1.81% was obtained. The OLED performance was drastically improved by using a solution-processed double-emitting layer device structure, and $\eta_{ext}$s of 8.55 and 7.46% were achieved for the present sky-blue phosphorescent bis- and tris-cyclometalated iridium(III) complexes, respectively (CIE chromaticity coordinates: (0.17, 0.33) and (0.17, 0.29), respectively).

1. Introduction

From the viewpoint of the development of highly efficient organic light-emitting diodes (OLED), electrophosphorescent devices have been attracting considerable attention for the last decade because they utilize both singlet and triplet excitons to achieve as high as 100% internal quantum efficiency, four times larger than that of electrofluorescent devices. As phosphorescent materials for OLED applications, organometallic complexes with a heavy metal center are reliable candidates, and organoiridium and organoplatinum complexes have been intensively developed, as demonstrated by the pioneering works of Thompson and coworkers because the strong spin–orbit coupling caused by the organometallic frameworks facilitates the intersystem crossing from the singlet state to the triplet. Especially, bis- and tris-cyclometalated iridium(III) complexes represented by (C^N)2Ir(LX) and (C^N)3Ir (C^N, 2-fluorophenyl)pyridinate-based homoleptic tris-cyclometalated ligand; LX, anionic ancillary ligand), respectively, show efficient phosphorescence with relatively high photoluminescence (PL) quantum yields, and their emission color is easily tuned by the well-designed C^N ligand. Although blue phosphorescent cyclometalated iridium(III) complexes are important as RGB emitters in the fabrication of OLED-based electric devices, such as full color displays and mercury-less illumination apparatuses, they are less frequently reported in comparison with green and red phosphorescent emitters. This is mainly because the structural variation of the C^N ligand to achieve the high-lying triplet level is considerably limited.
In the case of \((\text{C}^\text{N})_2\text{Ir}(\text{LX})\) and \((\text{C}^\text{N})_3\text{Ir}\), it is well known that the introduction of electron-withdrawing substituents, such as fluorene and trifluoromethyl, gives rise to stabilization of the highest occupied molecular orbital (HOMO) to yield a wide HOMO–LUMO energy gap (LUMO; lowest unoccupied molecular orbital), as a result, achieving the high-lying triplet level.\(^{1,2-3}\) For example, employing 2-(2,4-difluorophenyl)pyridine leads to sky-blue emission in combination with a picoline ancillary ligand.\(^{9,19-21}\) This \(\text{C}^\text{N}\) ligand is also effective in preparing a sky-blue phosphorescent emitter based on \((\text{C}^\text{N})_2\text{Ir}\).\(^{3}\) The \((\text{C}^\text{N})_2\text{Ir}(\text{LX})\)-type complex, consisting of 2-[3,5-bis(trifluoromethyl)phenyl]pyridine and dipivaloylmethane, is also useful as a blue emitter to fabricate a white phosphorescent OLED.\(^{23}\) Fewer examples of electron-withdrawing groups on the \(\text{C}^\text{N}\) ligand to obtain blue phosphorescence, however, have so far been reported, other than fluorene and fluoroalkyl substituents.

Recently, green phosphorescent \((\text{C}^\text{N})_2\text{Ir}(\text{LX})\)-type complexes consisting of 5’-benzoylated 2-phenylpyridine and acetylacetone (acac) were reported, where the PL maxima are blue-shifted by ca. 20 nm compared with \((\text{ppy})_2\text{Ir}(\text{acac})\) and \((\text{ppy})_3\text{Ir}\) (ppy; 2-phenylpyridinate).\(^{23}\) Thus, a benzoyl group is an effective electron-withdrawing group to obtain blue-shifted phosphorescence. Although blue-emitting organoiridium(III) complexes bearing fluoro groups as well as carbonyl groups, such as methoxycarbonyl\(^{24}\) and trifluoroacetyl,\(^{9,15,24}\) are reported, the impact of the combination of benzoyl with other electron-withdrawing group(s) on the emission color has never been investigated with respect to developing blue phosphorescent organoiridium complexes. Here, we report the synthesis and PL properties of novel bis- and tris-cyclometalated iridium(III) complexes bearing 5’-benzoylated 2-(4-fluorophenyl) and 2-(4,6-difluorophenyl)pyridinates as \(\text{C}^\text{N}\) ligands. We also report the fabrication and electroluminescent behavior of poly(9-vinylcarbazole)-based OLEDs using these phosphorescent complexes.

2. Results and discussion

2.1. Synthesis and molecular structures

The 3’-benzoylated 2-phenylpyridine derivatives, \((\text{HC}^\text{N})_2\text{Ir}\) and \((\text{HC}^\text{N})_3\text{Ir}\), were newly prepared as the \(\text{C}^\text{N}\) ligands in accordance with Scheme 1; 2-fluoro-5-(pyridin-2-yl)benzonitrile (2) was obtained by the Suzuki–Miyaura coupling reaction of \(\text{HC}^\text{N}-\text{Br}\) with \(\text{HC}^\text{N}-\text{Br}\) and \(\text{HC}^\text{N}-\text{Br}\) was obtained in three steps from 3-bromobenzonitrile (1) in 82% yield, and was subjected to the addition of phenylmagnesium bromide, followed by hydrolysis, to yield \((\text{HC}^\text{N})_2\text{Ir}\) in 28% yield. On the other hand, \((\text{HC}^\text{N})_3\text{Ir}\) was obtained in three steps from 3-bromo-2,6-difluorobenzaldehyde. First, the starting material was subjected to the Stille coupling reaction with 2-(tributylstannyl)pyridine to obtain the phenylpyridine derivative 3 in 78% yield, which was reacted with phenylmagnesium bromide to yield the alcohol 4 in 58% yield. Finally, oxidation of 4 with pyridinium dichromate (PDC) in dichloromethane afforded \((\text{HC}^\text{N})_3\text{Ir}\) in 90% yield. To obtain the referential complexes, \((\text{HC}^\text{N})_1\text{Ir}\) was prepared in a similar way to the preparation of \((\text{HC}^\text{N})_2\text{Ir}\), although it was previously reported to be obtained by the Stille-type coupling reaction of \((3\text{-bromophenyl})\text{phenylmethane} \times 2\) (tributylstannyl)pyridine.\(^{23}\)

The syntheses of the 5’-benzoyl-substituted bis- and tris-cyclometalated iridium(III) complexes are shown in Scheme 2. The prepared benzoylated 2-phenylpyridines were reacted with hydrated \(\text{IrCl}_3\) to obtain \(\mu\)-chloro-bridged iridium(III) dimers \([\text{(C}^\text{N}^\text{X})_2\text{IrCl}_2]\) \((X = 1–3)\) as precursors. These dinuclear complexes were reacted with acetylacetone in the presence of \(\text{Na}_2\text{CO}_3\) to afford the corresponding bis-cyclometalated complexes, \(\text{Ir}^\text{1a}\) (the referential complex, reported in ref. 23), \(\text{Ir}^\text{2a}\), and \(\text{Ir}^\text{3a}\). The reaction of \([\text{(C}^\text{N}^\text{X})_3\text{IrCl}_2]\) with picolinic acid was also carried out under the same conditions to obtain the picoline analogue, \(\text{Ir}^\text{3b}\). The tris-cyclometalated complexes, \(\text{Ir}^\text{1c}\), \(\text{Ir}^\text{2c}\), and \(\text{Ir}^\text{3c}\), were also prepared by the microwave-assisted reaction of the corresponding \([\text{(C}^\text{N}^\text{X})_3\text{IrCl}_2]\) with \((\text{HC}^\text{N})_3\text{Ir}\) in 15–59% yields. The prepared complexes were characterized by \(^1\)H NMR, ESI-TOF mass spectrometry, and IR spectroscopy, as well as elemental analyses; \(^{13}\)C NMR spectra were also taken, except for the fluorinated compounds.

Among the developed cyclometalated iridium(III) complexes, the structures of \(\text{Ir}^\text{3a}\) and \(\text{Ir}^\text{3c}\) were characterized by X-ray crystallographic analysis, where suitable single crystals were obtained by slow diffusion of dichloromethane solutions of the complexes to hexane. Fig. 1 shows ORTEP drawings of \(\text{Ir}^\text{3a}\) and \(\text{Ir}^\text{3c}\), and the crystal data are summarized in Table S1 (ESI†). The selected bond lengths and angles around the iridium center are also summarized in Tables S2 and S3 (ESI†). In the structure of \(\text{Ir}^\text{3a}\), the ligands are arranged in a pseudo-octahedral geometry with a \(\text{cis}-\text{C}^\text{C}\) and \(\text{trans}-\text{N}^\text{X}^\text{N}\) configuration, as is observed for the typical bis-cyclometalated iridium(III) complexes so far reported.\(^{6,8,23}\) The bond lengths are also similar to the typical heteroleptic complexes: the lengths of the \(\text{Ir}^\text{–N}\), \(\text{Ir}^\text{–N}\), and \(\text{Ir}^\text{–N}\) bonds are 2.135(3), 2.140(3), and 2.139(3) \(\text{Å}\), respectively.
C, and Ir–O bonds are 2.04, 1.99–2.00, and 2.13 Å, respectively. Likewise, Ir-3c adopts a pseudo-octahedral geometry with a facial configuration, similar to typical phosphorescent homoleptic complexes, where the lengths of Ir–N and Ir–C bonds are 2.12–2.13 and 2.02–2.03 Å, respectively. It has been reported that the thermodynamically favored facial isomer is more emissive than the kinetically favored meridional one, and thus Ir-3c is expected to afford highly efficient phosphorescence. For Ir-3a and Ir-3c, the carbonyl moiety in each benzoyl group is distorted at 76.0–77.6° and 60.2–87.6°, respectively, with respect to the mean plane of the neighbouring phenyl ring of the C=N ligand. In addition, the phenyl and carbonyl moieties in the benzoyl group are twisted at 1.7–3.3° (Ir-3a) and at 2.9–25.4° (Ir-3c) to each other. The effect of the benzoyl group on the electronic structures is discussed below.

2.2. Light absorption and photoluminescent properties

UV-vis absorption spectra of the bis- and tris-cyclometalated iridium(III) complexes were obtained in dichloromethane at rt, as shown in Fig. 2, and the spectral data are also summarized in Table 1. The absorption spectra of Ir-1a–3a and Ir-3b are shown in Fig. 2a. In the case of Ir-1a, intense absorption bands are observed from 250–320 nm, which are assigned to the spin-allowed ligand-center (1LC, 1p–p*) transitions at the C=N ligand, and the next bands at 330–420 nm are assigned to spin-allowed metal-to-ligand charge transfer (1MLCT, 1d–p*) transitions from the iridium core to the C=N ligand. As seen in the magnified spectrum, the weak shoulder-like absorption band around 475 nm with a lower molecular absorptivity is assigned to the spin-forbidden 3MLCT transition. Similar spectral
features to Ir-1a are observed for the other bis-cyclometalated complexes, where the \(^3\)MLCT transition bands are blue-shifted to 465, 460 and 450 nm for Ir-2a, Ir-3a and Ir-3b, respectively, and the absorption onsets are also blue-shifted. This clearly indicates that the lowest triplet (T\(_1\)) energy increases with an increase in the number of fluorine substituents, as well as after the replacement of the acac ancillary ligand with picolinate. In the case of the tris-cyclometalated complexes, the absorption spectral profiles are almost similar to those of the bis-cyclometalated complexes bearing the corresponding C\(^{-}\)N ligands: the \(^1\)LC (250–300 nm), \(^3\)MLCT (300–410 nm), and \(^3\)MLCT (>440 nm) transitions are observed from the near-ultraviolet to the neighboring visible region (Fig. 2b). As observed for the bis-cyclometalated complexes, the \(^3\)MLCT transition band as well as the spectral onset is blue-shifted with an increase in the number of fluorine substituents.

The photoluminescence (PL) spectra of bis- and tris-cyclometalated iridium(III) complexes in dichloromethane at rt are shown in Fig. 3. The spectral data are summarized in Table 1, along with PL quantum yields (\(\Phi_{PL}\)) and PL lifetimes (\(\tau_{PL}\)). All the data were obtained for deaerated samples, which were kept away from luminescence quenching by oxygen. In the spectra of the bis-cyclometalated complexes (Fig. 3a), the \(\lambda_{PL}\) of Ir-1a was observed at 502 nm (green), and the emission band was blue-shifted with an increase in the number of fluorine substituents: Ir-2a and Ir-3a show their \(\lambda_{PL}\) at 483 (bluish green) and 479 nm (bluish green), respectively. For the C\(^{-}\)N-3-derived complexes, replacement of the acac ancillary ligand with picolinate gives rise to a further blue shift of 15 nm (\(\lambda_{PL}\) of Ir-3b; 464 nm), yielding sky-blue emission. Such a blue shift induced by picolinate is usually observed in typical bis-cyclometalated complexes.\(^{8,37}\) The blue shifts caused by the fluorine substituents as well as the ancillary ligand replacement are comparable to the blue-shifted spectral behaviour of the \(^3\)MLCT absorption \(\text{(vide supra)}\). The \(\Phi_{PL}\) values of Ir-1a, Ir-2a, Ir-3a and Ir-3b were determined as 0.81, 0.71, 0.80 and 0.82, respectively. Also, the \(\tau_{PL}\) of these complexes ranged from 1.01 to 1.97 \(\mu\)s, each of which was well fitted to a single-exponential decay. Fernández-Sánchez and coworkers reported \((\text{MeOCOdfppy})_2\text{Ir}(\text{pic})\) (MeOCODfppy, 2-(4,6-difluoro-5-methoxycarbonylphenyl)
pyridinate; pic, picolinate) and \((\text{CF}_3\text{CODfppy})_2\text{Ir(pic)}\) \((\text{CF}_3\text{CODfppy})_2\); 2,4,6-difluoro-5-(trifluoroacetyl)phenyl)pyridinate), which have a methoxycarbonyl and a trifluoroacetyl group, respectively, instead of the benzoyl group of \(\text{Ir-3b}\). The complexes exhibited blue and deep blue PL at 463 and 459 nm, where the \(\Phi_{\text{PL}}\) s are 0.44 and 0.08 in acetonitrile, respectively.\(^\text{24}\) The \(\lambda_{\text{PL}}\) of \(\text{Ir-3b}\) is comparable to that of \((\text{MeOOCODfppy})_2\text{Ir(pic)}\) and is red-shifted by 5 nm in comparison with that of \((\text{CF}_3\text{CODfppy})_2\text{Ir(pic)}\). One can see that this is because the electron-withdrawing ability of a benzoyl group is comparable to that of a methoxycarbonyl group and lower than that of a trifluoroacetyl group: the Hammett substituent constants \((\sigma_P)\) of benzoyl, methoxycarbonyl and trifluoroacetyl groups are 0.43, 0.45 and 0.80, respectively.\(^\text{24}\) On the other hand, the \(\Phi_{\text{PL}}\) of \(\text{Ir-3b}\) is 0.94 in acetonitrile, which is much higher than that of \((\text{MeOOCODfppy})_2\text{Ir(pic)}\) and \((\text{CF}_3\text{CODfppy})_2\text{Ir(pic)}\). As seen in Fig. 3b, the \(\lambda_{\text{PL}}\) s of \(\text{Ir-1c}, \text{Ir-2c}\) and \(\text{Ir-3c}\) were observed at 487 (bluish green), 470 (bluish green) and 463 nm (sky blue), respectively, blue-shifted by 14–17 nm in comparison with those of the corresponding acac-based bis-cyclometalated complexes. These blue shifts are caused by the relatively high ligand field strength of the \(\text{C}^\text{N}\) ligands in comparison with the acetylacetone and picolinate anions.\(^\text{23,28}\) Thompson and coworkers reported that \(\text{fac-(dfppy)}_2\text{Ir(dfppy; 2,4,6-difluoro-5-(trifluoroacetyl)phenyl)pyridinate}\) exhibits blue PL at 468 nm in dichloromethane at rt.\(^\text{3}\) In the present case, the \(\lambda_{\text{PL}}\) of \(\text{Ir-3c}\) is 5 nm shorter than that of \(\text{fac-(dfppy)}_2\text{Ir}\). This blue-shift is obviously brought about by the introduction of a benzoyl group to the \(\text{C}^\text{N}\) ligand. The \(\Phi_{\text{PL}}\) s of \(\text{Ir-1c}, \text{Ir-2c}\) and \(\text{Ir-3c}\) were determined as 0.82, 0.85 and 0.90, respectively. Their \(\tau_{\text{PL}}\) s were determined as 1.16–1.57 ms, similar to those of the corresponding bis-cyclometalated complexes. It is worthy to note that \(\text{Ir-3c}\) is more emissive than the representative blue phosphorescent organoiridium complexes, such as \(\text{fac-(dfppy)}_2\text{Ir(\Phi_{\text{PL}}; 0.43)}\) and \(\text{bis[4,6-difluoro-5-(trifluoroacetyl)phenyl]pyridinate-N,C}_2\text{Ir(\text{implement-N,O), FfpIr(\Phi_{\text{PL}}; 0.87)}}\).\(^\text{21}\)

To determine the \(\text{T}_1\) energy values \((E_{\text{T}_1})\), the phosphorescence spectra were measured in deaerated 2-MeTHF glassy matrices at 77 K (Fig. S2, ESI), and the spectral data are also summarized in Table 1. All of the complexes are also intensely phosphorescent in the present case, the \(E_{\text{T}_1}/E_{\text{HOMO}}\) of \(\text{Ir-1c}\) and \(\text{Ir-3c}\), respectively, instead of the benzoyl group of \(\text{Ir-3b}\). The \(E_{\text{T}_1}/E_{\text{HOMO}}\) values were determined as \(-5.46, -5.55\) and \(-5.67\) eV, respectively, indicating that the HOMO is stabilized by an increase in the number of fluorine substituents. In addition, a benzoyl group also stabilizes the HOMO: the \(E_{\text{HOMO}}\) of \((\text{ppy})_2\text{Ir(acac)}\) is reported as \(-5.2\) eV.\(^\text{27}\) For \(\text{Ir-3b}, E_{\text{HOMO}}\) was determined as \(-5.81\) eV, larger in a negative direction than that of \(\text{Ir-3a}\) (\(-5.67\) eV). This indicates that the replacement of the ancillary ligand by picolinate also gives rise to stabilization of the HOMO level. In the case of the tris-cyclometalated complexes, the \(E_{\text{HOMO}}\) values were determined as \(-5.57, -5.73\) and \(-5.83\) eV for \(\text{Ir-1c}, \text{Ir-2c}\) and \(\text{Ir-3c}\), respectively. As is seen in the bis-cyclometalated complexes, the HOMO level of the tris-cyclometalated complex is stabilized by an increase in the number of fluorine substituents. Also, it is more stabilized in comparison with those of the corresponding bis-cyclometalated complexes \(\text{i.e., Ir-1a-3a}\).

### 2.4. DFT calculations

In order to discuss the effect of benzoyl and fluorine substituents on the \(E_{\text{HOMO}}\), density functional theory (DFT) calculations were performed for the tris-cyclometalated complexes, using the Gaussian 09 program package.\(^\text{23}\) The structures of \(\text{Ir-1c}, \text{Ir-2c}\) and \(\text{Ir-3c}\) were optimized using the B3LYP functional,\(^\text{13}\) where the crystal structure of \(\text{Ir-3c}\) was used as an initial structure. LanL2DZ and 6-31G+(d) basis sets were employed for iridium and the other atoms, respectively, where LanL2DZ is one of the relativistic effective core potential (RECP) basis sets and consists of relativistic effective potentials and their associated basis sets.\(^\text{24}\) The optimized structure and the spatial

### Fig. 4

Optimized geometry structure and electron configurations of (a) HOMO and (b) LUMO for \(\text{Ir-1c}\).
distributions of the HOMO and LUMO of \textit{Ir-1c} are shown in Fig. 4. Those of \textit{Ir-2c} and \textit{Ir-3c} are similar to \textit{Ir-1c} (Fig. S4, ESI†). The calculated energy levels of the HOMO and LUMO (\(E_{\text{HOMO,calcd}}\) and \(E_{\text{LUMO,calcd}}\), respectively) of these complexes are summarized in Table 3, together with the HOMO–LUMO energy gaps (\(E_{\text{g,calcd}}\)). The spatial distributions of the HOMOs and LUMOs of these complexes are almost the same as those of typical (ppy)\textsubscript{3}Ir-type complexes,\textsuperscript{19,27} and the carbonyl group shows an electronic contribution to both the HOMO and LUMO, in spite of disrupted \(\pi\)-conjugation due to deviation from the phenylpyridine plane. The \(E_{\text{HOMO,calcd}}\) value of each complex is comparable to the \(E_{\text{HOMO}}\) determined by CV, and an increase in the number of fluorine substituents leads to stabilization of the HOMO. Although the \(E_{\text{LUMO,calcd}}\) is also decreased by an increase in the fluorine substituents, the \(E_{\text{HOMO,calcd}}\) is decreased more drastically than \(E_{\text{LUMO,calcd}}\). This indicates that the high-lying triplet state is brought about by stabilization of the HOMO.

2.5. Fabrication of phosphorescent OLEDs

Using the developed bis- and tris-cyclometalated iridium(III) complexes as a phosphorescent dopant, we fabricated OLEDs consisting of a poly(9-vinylcarbazole) (PVCz) emitting layer (EML), device-1. The device structure is as follows: ITO (transparent anode, 150 nm, 10 \(\Omega\) per square)/poly(3,4-ethylenedioxythiophene):poly(styrene-sulfonate) (PEDOT:PSS, 10 nm)/EML (100 nm)/CsF (1.0 nm)/Al (cathode, 250 nm). The EML consists of PVCz (hole-transporting host material), 1,3-bis[5-(4-(tert-butyl)phenyl)-1,3,4-oxadiazol-2-yl]benzene (OXD-7, electron-transporting material), and the phosphorescent dopant in a ratio of 10 : 3.0 : 0.40 (wt/wt/wt). The electroluminescence (EL) spectra of the fabricated devices are shown in Fig. 5, and the device properties are also summarized in Table 4. In the case of the bis-cyclometalated complexes, the devices exhibited EL spectra almost identical to the PL spectra of the constituent emitting dopants; the EL wavelengths (\(\lambda_{\text{EL}}\)) of the \textit{Ir-1a}, \textit{Ir-2a}, and \textit{Ir-3a}-doped devices were 507, 485, and 481 nm, respectively. As for the Commission Internationale de L’éclairage (CIE) chromaticity coordinates (CIE \((x, y)\)), the \textit{Ir-3a}-doped device afforded a value of (0.19, 0.42). The ancillary ligand replacement from acac to picolinate allowed us to fabricate an OLED emitting further blue-shifted EL: the device doped with \textit{Ir-3b} exhibited sky-blue EL with a \(\lambda_{\text{EL}}\) of 469 nm and afforded a CIE \((x, y)\) of (0.18, 0.34), where the value of the \(y\)-axis was improved in comparison with the \textit{Ir-3a}-doped device. In terms of the device efficiency, the maximum external quantum efficiency (\(\eta_{\text{ext}}\)) decreased slightly with an increase in the fluorine substituents; 2.44 (@10.0 V), 2.13 (@10.0 V), and 1.90% (@9.5 V) for the \textit{Ir-1a}, \textit{Ir-2a}, and \textit{Ir-3a}-doped devices, respectively. In addition, the ancillary ligand replacement from acac to picolinate gave rise to deterioration of \(\eta_{\text{ext}}\) down to 1.72% (@10.5 V, the \textit{Ir-3b}-doped device). One can see that an increase in the \(E_{\text{T}}\) is likely to bring about a back energy transfer to OXD-7 (\(E_{\text{T}} = 2.7\) eV).\textsuperscript{22}

In the case of the tris-cyclometalated complexes, the \textit{Ir-3c}-doped device exhibited the most blue-shifted EL (\(\lambda_{\text{EL}}\): 462 nm) among the OLEDs fabricated in this study. As expected from the results described above, the \textit{Ir-1c}-doped device showed a better performance (\(\eta_{\text{ext}}\): 2.31% @ 11.0 V) than the \textit{Ir-2c} (\(\eta_{\text{ext}}\): 2.10% @ 10.5 V) and \textit{Ir-3c}-doped devices (\(\eta_{\text{ext}}\): 1.81% @ 8.0 V): the increase in the number of fluorine substituents afforded a comparable or higher \(E_{\text{T}}\) to facilitate the back energy transfer to OXD-7. In the \textit{Ir-3c}-doped device, however, both the \(x\) and \(y\)-axis values of the CIE chromaticity coordinate were improved in comparison with the \textit{Ir-3b}-doped device, yielding a CIE \((x, y)\) of (0.16, 0.28). This value is better than that of FIrpic (CIE \((x, y)\) of (0.17, 0.34)), which is frequently used as a blue phosphorescent material.\textsuperscript{22}

In order to improve the device efficiency of blue OLEDs, solution-processed multilayer OLEDs employing \textit{Ir-3} were fabricated (device-2), which have a so-called double-emitting layer (D-

In summary, novel blue phosphorescent bis- and tris-cyclometalated iridium(III) complexes with excellent PL quantum yields were successfully developed. In a series of bis-cyclometalated complexes, the 2-(4,6-difluoro-5-benzoylphenyl) pyridinate-based complex (Ir-3b) exhibited the most blue-shifted PL in combination with a picoline ancillary ligand. A PVCz-based OLED, using Ir-3b as an emitting dopant, exhibited sky-blue EL along with a CIE (x,y) of (0.18, 0.34). Further ligand replacement with the identical C^N ligand afforded a facial isomer of the homoleptic tris-cyclometalated complex (Ir-3c), which also exhibited sky-blue PL. This tris-cyclometalated complex was an excellent blue phosphorescent dopant for OLED application with respect to the chromaticity coordinates, where the Ir-3b-based device afforded a CIE (x,y) of (0.16, 0.28). Although the PVCz-based OLEDs employing OXD-7 as an electron-transporting material showed low \eta_{ext} (~2%), D-EML OLEDs doped with Ir-3 showed an improved \eta_{ext} of 6.68-8.55% without any considerable changes in the CIE coordinates. From the results of electrochemical and DFT studies, it was revealed that the blue-shifted PL and EL are mainly brought about by stabilization of the HOMO. Therefore, this work clearly demonstrates that the introduction of a benzoyl substituent into a fluorinated 2-phenylpyridinate cyclometalated ligand provides an opportunity to develop blue phosphorescent organoiridium(n) complexes with improved CIE chromaticity coordinates.

3. Conclusions

In summary, novel blue phosphorescent bis- and tris-cyclometalated iridium(III) complexes with excellent PL quantum yields were successfully developed. In a series of bis-cyclometalated complexes, the 2-(4,6-difluoro-5-benzoylphenyl) pyridinate-based complex (Ir-3b) exhibited the most blue-shifted PL in combination with a picoline ancillary ligand. A PVCz-based OLED, using Ir-3b as an emitting dopant, exhibited sky-blue EL along with a CIE (x,y) of (0.18, 0.34). Further ligand replacement with the identical C^N ligand afforded a facial

4. Experimental

4.1. Synthesis

All chemicals used for synthesis were purchased from Sigma-Aldrich Co., Tokyo Chemical Industry Co., Ltd, and Wako Pure Chemical Industries, Ltd and used without further purification. NMR spectra (\textsuperscript{1}H and \textsuperscript{13}C) were obtained on a Jeol JNM-ECX400 (400 MHz for \textsuperscript{1}H and 100 MHz for \textsuperscript{13}C) spectrometer, using TMS as an internal standard (0.00 ppm). Electrospray ionization (ESI) mass spectra were measured on a Jeol JMS-T100LP. Elemental analyses were carried out on a J-Science Lab MICRO CORDER J10 analyzer.
4.2. General procedure of synthesis of 1 and 2

To a mixture of 2-iodypyridine (0.25 g, 1.2 mmol), arylboronic acid (1.8 mmol), and PdCl2(PPh3)2 (0.069 g, 0.098 mmol) in a solvent mixture of benzene (5 mL) and ethanol (2 mL) was added Na2CO3aq (2 M, 5 mL). Then, the mixture was heated at 80 °C for 24 h under nitrogen. After cooling, the solution was removed on a rotary evaporator. The residue was dissolved in dichloromethane, and the solution was washed with water (50 mL × 2) and sat. brine, and then dried over anhydrous MgSO4. The solvent was removed on a rotary evaporator, and the residue was purified by silica gel column chromatography using dichloromethane as eluent to obtain the target arylpyridine derivative.

3-(Pyridin-2-yl)benzonitrile (1). 95% yield. 1H NMR (400 MHz, CDCl3) δ 7.31 (ddd, J = 1.4, 4.8 and 7.4 Hz, 1H), 7.57 (t, J = 7.8 Hz, 1H), 7.68 (td, J = 1.4 and 7.8 Hz, 1H), 7.71–7.75 (m, 1H), 7.80 (dt, J = 1.8 and 7.8 Hz, 1H), 8.23 (td, J = 1.4 and 7.8 Hz, 1H), 8.31 (t, J = 1.4 Hz, 1H), 8.70–8.73 (m, 1H). This compound has been reported in ref. 37.

2-Fluoro-5-(pyridin-2-yl)benzonitrile (2). 81% yield. 1H NMR (400 MHz, CDCl3) δ 7.34 (m, 2H, masked by CHCl3), 7.32 (d, J = 2.91 (td, J = 1.4 and 9.2 Hz, 1H), 7.37 (m, 2H), 7.42 (d, J = 2.91 (td, J = 1.4 and 9.2 Hz, 1H), 7.59 (dd, J = 1.8 Hz, 1H), 7.69–7.73 (m, 2H), 7.87 (d, J = 8.2 Hz, 2H), 8.15 (dd, J = 2.5 and 6.6 Hz, 1H), 8.18–8.23 (m, 1H), 8.65–8.69 (m, 1H), IR (KBr, cm−1) 602, 756, 849, 1157, 1250, 1435, 1472, 1504, 2223. ESI-MS: m/z [M + H]+ calcd for C12H7F2NO: 220.06; found: 220.07. Anal. calcd for C, 77.79; H, 4.35; N, 5.06.

4.3. Synthesis of 2,6-difuoro-3-(pyridin-2-yl)benzaldehyde (3)

A mixture of 3-bromo-2,6-difluorobenzaldehyde (0.442 g, 2.03 mmol) and Pd[PPh3]2 (0.121 g, 0.104 mmol) in dry toluene (10 mL) was heated up to 80 °C, then 2-(tributylstannyl)pyridine (0.884 g, 4.40 mmol) was added. The mixture was refluxed for 24 h. After the solution was cooled to rt, the reaction mixture was quenched with a saturated aqueous KF solution (10 mL). The solution was dissolved in dichloromethane (100 mL), washed with water (50 mL × 2) and sat. brine (100 mL), and then dried over anhydrous MgSO4. The solvent was removed on a rotary evaporator, and the residue was purified by silica gel column chromatography using ethyl acetate/hexane (2/3, v/v) as eluent to afford a white solid of 3 (0.346 g, 1.59 mmol, 78%). 1H NMR (400 MHz, CDCl3) δ 7.13 (dt, J = 1.4 and 9.2 Hz, 1H), 7.30–7.34 (m, 2H), 8.20 (td, J = 6.4 and 8.7 Hz, 1H), 8.74 (td, J = 1.4 and 5.0 Hz, 1H), 10.40 (s, 1H). IR (KBr, cm−1) 501, 679, 756, 847, 1227, 1296, 1589, 1643. ESI-MS: m/z [M + H]+ calcd for C12H12F2NO: 220.06; found: 220.07. Anal. calcd for C, 65.76; H, 3.22; N, 6.39. Found: C, 65.62; H, 3.50; N, 6.30.

4.4. General procedure of synthesis of HC*N-1, HC*N-2, and HC*N-3

A solution of phenylmagnesium bromide was prepared by dropwise addition of bromobenzene (1.57 g, 10 mmol) in 15 mL of dry THF via a dropping funnel to magnesium turnings (0.323 g, 13.3 mmol) suspended in dry THF (5 mL) under N2 at rt, where vigorous stirring was essential. The obtained solution of the Grignard reagent (12 mL) was added slowly to a solution of 1–3 (2 mmol) in dry THF (4 mL), and then the reaction mixture was heated at reflux for 5 h. After cooling, 1 M H2SO4 (10 mL) was added, and the obtained mixture was stirred at rt for 2 h, followed by neutralization using a saturated aqueous solution of NaHCO3. After the mixture was concentrated on a rotary evaporator, dichloromethane (50 mL) was added to the residual solution. This mixture was vigorously shaken in a separation funnel, and the organic layer was separated, washed with water (50 mL × 2) and sat. brine, and then dried over anhydrous MgSO4. The solvent was removed on a rotary evaporator, and the residue was purified by silica gel column chromatography using ethyl acetate/hexane (1/3, v/v) to obtain the product.

Phenyl-3-(pyridin-2-yl)phenyl)methanone (HC*N-1). 81% yield. 1H NMR (400 MHz, CDCl3) δ 7.22–7.29 (m, 1H), 7.49 (t, J = 7.6 Hz, 2H), 7.58–7.62 (m, 2H), 7.75–7.78 (m, 2H), 7.81–7.86 (m, 3H), 8.26 (td, J = 1.4 and 7.8 Hz, 1H), 8.39 (t, J = 1.8 Hz, 1H), 8.69 (d, J = 5.0, 1H). This compound has been reported in ref. 23.

2-Fluoro-5-(pyridin-2-yl)phenyl)(phenyl)methanol (4).

(2-Fluoro-5-(pyridin-2-yl)phenyl)(phenyl)methanone (HC*N-2). 28% yield. 1H NMR (400 MHz, CDCl3) δ 7.22–7.29 (m, 2H, masked by CHCl3), 7.48 (t, J = 7.7 Hz, 2H), 7.60 (tt, J = 1.4 and 7.3 Hz, 1H), 7.69–7.79 (m, 2H), 8.77 (d, J = 8.2 Hz, 2H), 8.15 (dd, J = 2.5 and 6.6 Hz, 1H), 8.18–8.23 (m, 1H), 8.65–8.69 (m, 1H), IR (KBr, cm−1) 602, 756, 849, 1157, 1250, 1312, 1412, 1504, 1597, 1659. ESI-MS: m/z [M + Na]+ calcd for C18H12FNNaO: 300.08; found: 300.07. Anal. calcd for C18H12F3NO: C, 77.97; H, 4.36; N, 5.05. Found: C, 77.79; H, 4.35; N, 5.06.

(2,6-Difluoro-3-(pyridin-2-yl)phenyl)(phenyl)methanol (4).

4.5. Synthesis of 2,6-difuoro-3-(pyridin-2-yl)phenyl)(phenyl)methanone (HC*N-3)

To a solution of 4 (0.243 g, 0.820 mmol) in dichloromethane (40 mL) was added a 4 Å molecular sieve (0.832 g) and pyridinium dichromate (0.539 g, 1.45 mmol) at rt. The reaction mixture was stirred at rt for 8 h, then the suspension was filtered over a Celite® pad, and the solution was evaporated to dryness. The residue was dissolved in dichloromethane (100 mL), and the solution was washed with water (50 mL × 2) and sat. brine (100 mL), and then dried over anhydrous MgSO4. The solvent was removed on a rotary evaporator, and the residue was purified by silica gel column chromatography using ethyl acetate/chloroform (1/10, v/v) as eluent to afford a pale yellow oil, HC*N-3 (0.217 g, 0.735 mmol, 90%). 1H NMR (400 MHz, CDCl3) δ 7.10–7.16 (m, 1H), 7.24–7.30 (m, 1H, masked by CHCl3), 7.49 (t, J = 7.7 Hz, 2H), 7.62 (t, J = 7.7 Hz, 1H), 7.72–7.75 (m, 2H), 7.90
(d, J = 7.7 Hz, 2H), 8.16 (dd, J = 6.8 and 8.6 Hz, 1H), 8.72 (d, J = 4.3 Hz, 1H). IR (KBr, cm$^{-1}$) 764, 1065, 1126, 1258, 1319, 1582, 1666, 3063. ESI-MS: m/z [M + Na]$^+$ calcd for C$_{18}$H$_{11}$F$_2$NNaO: 318.07; found: 318.07. Anal. calcld for C$_{18}$H$_{11}$F$_2$NNaO: C, 73.72; H, 3.75; N, 4.74. Found: C, 73.21; H, 3.94; N, 4.77.

4.6. General procedure of synthesis of μ-chloro-bridged iridium[μ] dimers [{C$^N$-X}Ir$_2$Cl$_2$]

The μ-chloro-bridged iridium[μ] dimers [{C$^N$-X}Ir$_2$Cl$_2$] (X = 1–3) were prepared according to the conventional procedure.$^6$ To a solution of the cyclometalated ligand (HC$^N$-X, 2.5 mmol) in 2-ethoxyethanol (50 mL) was added a solution of IrCl$_3$·3H$_2$O (1.2 mmol) in water (50 mL), and the mixture was heated at 100 °C in an oil bath for 18 h. After cooling, water (100 mL) was added, and the obtained precipitate was collected by filtration and washed with ethanol (20 mL) and hexane (20 mL) to afford [{C$^N$-X}Ir$_2$Cl$_2$] in 83, 88 and 74% yields for X = 1, 2 and 3, respectively. The obtained materials were highly insoluble, and thus were used in the next reaction without further purification in accordance with conventional procedures.

4.7. General procedure of synthesis of bis-cyclometalated complexes

A mixture of [{C$^N$-X}Ir$_2$Cl$_2$] (0.10 mmol), acetylacetone or picolinic acid (0.40 mmol), and Na$_2$CO$_3$ (0.18 g, 1.7 mmol) in 2-ethoxyethanol (30 mL) was heated at 100 °C under nitrogen for 2 h. After cooling, the solvent was removed on a rotary evaporator. The residue was dissolved in dichloromethane, and the solution was washed with water (20 mL × 2) and sat. brine, and dried over anhydrous Na$_2$SO$_4$. The solvent was removed on a rotary evaporator, and the residue was puriﬁed by alumina column chromatography using dichloromethane as eluent. Further puriﬁcation was carried out by recrystallization from chloroform–hexane or dichloromethane–hexane.

Bis[2-(5-benzoylphenyl)pyridinato-N,C$^2$]iridium(III) (Ir-1a).

A mixture of [{C$^N$-X}Ir$_2$Cl$_2$] (0.050 mmol) and HC$^N$-X (0.55 mmol) in glycerol (30 mL) was added. This flask was set up in a J-Science Lab GM-IC Microwave Applicator, and irradiated with microwaves (2450 MHz, 300 W), and the suspension was refuxed for 1 h. After cooling, the reaction mixture was added to 100 mL of 3% NaCl$_2$aq. The resultant suspension was extracted with ethyl acetate/hexane (1/2, v/v), and dried over anhydrous Na$_2$SO$_4$. The solvent was removed on a rotary evaporator, and the residue was puriﬁed by silica gel column chromatography using ethyl acetate/hexane (2/1, v/v) as eluent. Further puriﬁcation was carried out by recrystallization from chloroform–hexane or dichloromethane–hexane.

4.8. General procedure of synthesis of tris-cyclometalated complexes

In a 50 mL round-bottom flask, a mixture of [{C$^N$-X}Ir$_2$Cl$_2$], (0.050 mmol) and HC$^N$-X (0.55 mmol) in glycerol (30 mL) was added. This flask was set up in a J-Science Lab GM-IC Microwave Applicator, and irradiated with microwaves (2450 MHz, 300 W), and the suspension was refuxed for 1 h. After cooling, the reaction mixture was added to 100 mL of 3% NaCl$_2$aq. The resultant suspension was extracted with ethyl acetate/hexane (1/2, v/v) as eluent. Further puriﬁcation was carried out by recrystallization from chloroform–hexane or dichloromethane–hexane.
chromated Mo-K\textsubscript{α} recorded relative to an Ag/AgNO\textsubscript{3} (0.1 M) reference electrode in tetrabutylammonium perchlorate as a support electrolyte at room temperature. The potentials were measured in deaerated acetonitrile, where the \( \text{SIR92} \) (ref. 39) programs for \text{Crystal Structure 4.0} (ref. 41) and \text{Crystal Structure 3.8} (ref. 42) software packages for \text{Ir-3a} and \text{Ir-3c}, respectively. The crystal data and refinement details of the crystal structure determination are given in Table S1 (ESI\textsuperscript{†}).

4.12. Fabrication of OLEDs
For fabrication of OLEDs, PVCz \( (M_w = 25\,000–50\,000) \) was purchased from Sigma-Aldrich Co., and used after purification by reprecipitation from THF to methanol. PEDOT:PSS (Clevios P CH 8000) and OXD-7 were purchased from Heraeus GmbH and Luminescence Technology Corp., respectively. BPOPB was prepared according to a literature report.\textsuperscript{36} Cesium fluoride and aluminium wires were purchased from Wako Pure Chemical Industries, Ltd. and the Nilaco Co., respectively.

Fabrication of device-1. A pre-patterned ITO glass substrate as an anode was routinely cleaned by ultrasonic treatment in an aqueous detergent solution, distilled water, acetone, chloroform, hexane and 2-propanol. PEDOT:PSS (40 nm) was spin-coated onto an ITO layer pretreated with UV-O\textsubscript{3} and then dried at 115 °C for 1 h. For fabrication of an EML, a mixture of PVCz, OXD-7, and an organoiridium(III) complex in dry toluene was filtered through a 0.2 μm Millex-FG filter (Millipore). The obtained stock solution was then spin-coated onto the PEDOT:PSS layer under an argon atmosphere. Thereafter, cesium fluoride (1.0 nm) and aluminium (250 nm) layers were successively embedded on the EML by vacuum deposition with a base pressure of \( 1.0 \times 10^{-4} \) Pa. Finally, the device was covered with a glass cap and encapsulated with a UV-curing epoxy resin under a dry argon atmosphere to keep oxygen and moisture away from the device. The emitting area was 10 mm\textsuperscript{2} (2 mm × 5 mm). The device fabrication was carried out in a glovebox filled with dry argon, except for the preparation of the PEDOT:PSS layer.

Fabrication of device-2. A PEDOT:PSS layer (40 nm) was fabricated on an ITO glass substrate using the same method as for device-1. For fabrication of an EML-1, a mixture of PVCz and an organoiridium(III) complex in dry toluene was filtered through a 0.2 μm Millex-FG filter (Millipore). The obtained stock solution was then spin-coated onto the PEDOT:PSS layer under an argon atmosphere. Then, for fabrication of an EML-2, a mixture of BPOPB and an organoiridium(III) complex in dry 2-propanol was filtered through a 0.2 μm Millex-FG filter (Millipore). The obtained stock solution was then spin-coated onto the EML-1 under an argon atmosphere. Thereafter, cesium fluoride (1.0 nm) and aluminium (250 nm) layers were embedded, and then the device was covered with a glass cap in the same way as device-1.
