A smart "off-on" gate for the in situ detection of hydrogen sulphide with Cu(II)-assisted europium emission*

Zhenhao Liang,^{ab} Tik-Hung Tsoi,^b Chi-Fai Chan,^c Lixiong Dai,^{bc} Yudan Wu,^a Guangyan Du,^a Lizhi Zhu,^{ab} Chi-Sing Lee,^{*a} Wing-Tak Wong,^{*b} Ga-Lai Law^{*b} and Ka-Leung Wong*c

A water-soluble and emissive Eu-complex (EuL1) bearing a $DO3A(Eu^{3+})$ -pyridine-aza-crown motif has been prepared and its Cu²⁺ complex has been demonstrated to be a smart luminescence "off-on" gate for H₂S detection in water with a nano-molar detection limit (60 nM). EuL1 binds to Cu²⁺ ions selectively $(K_{\rm R} = 1.2 \times 10^5 \text{ M}^{-1})$ inducing 17-fold luminescence guenching and forming a 1:1 stoichiometric complex (EuL1-Cu²⁺), which responds to H_2S selectively with restoration of the original Eu emission of EuL1 followed by a further 40-fold luminescence enhancement, forming a 1:1 stoichiometric complex (EuL1-Na₂S, $K_{B} = 1.5 \times 10^{4} \text{ M}^{-1}$). Without Cu²⁺ ions, EuL1 showed non-specific binding towards H₂S with only a 5-fold luminescence enhancement.

Introduction

Hydrogen sulphide (H_2S) is the smallest bioactive thiol that may act as a gaseous signalling agent,1 and its production in different tissue types is associated with a wide range of physiological responses such as vascular smooth muscle relaxation,² mitochondrial ATP production,³ insulin-signalling inhibition,⁴ regulation of inflammation response⁵ and mediation of neurotransmission.6 Moreover, recent investigations show that abnormal levels of H₂S are associated with a variety of diseases, such as neurodegenerative diseases,7 diabetes8 and cancer.9 However, the biological targets of H₂S and the mechanisms of these H₂S-related physiological phenomena remain unclear. Therefore the development of responsive and reversible luminescence probes for non-invasive real time monitoring of H₂S may be useful for understanding its biological modes of action.

One of the major approaches for developing luminescence H₂S detection¹⁰ is based on sulphide-specific chemical reactions, such as reduction of an azide11 and nucleophilic addition of a sulphide ion.¹² This type of luminescence probe is generally irreversible and usually requires a considerably long incubation

^aLaboratory of Chemical Genomics, School of Chemical Biology and Biotechnology, Peking University Shenzhen Graduate School, Shenzhen University Town, Xili, Shenzhen 518055, China. E-mail: lizc@pkusz.edu.cn

time. An alternative approach is based on CuS precipitation¹³ due to the low-solubility of CuS ($K_{\rm sp} = 6.3 \times 10^{-36}$). These luminescence probes are generally reversible with low detection limits. We are particularly interested in developing H₂S luminescence sensors based on organo-lanthanide complexes due to their water-solubility and unique photophysical properties, including line-like emission spectra and long luminescence lifetimes (micro to milli second scale) that can effectively separate the observing signal from biological autofluorescence noise and are suitable for time-gated detection. Recently, a few studies have been found in the literature with irreversible H₂S lanthanide probes.12a Herein, we report the development of a novel responsive europium-based luminescence "off-on" gate for the *in situ* detection of H₂S in water.

As illustrated in Fig. 1, EuL1 contains a DO3A–Eu³⁺ complex and an aza-18-crown-6 moiety, which are linked to the 2- and 6positions of a pyridine-containing chromophore constituting a switch-like structure. In the ground state, EuL1 should be emissive due to the coordination of the pyridine chromophore

Chemical Science

to a Eu^{3+} ion, which favours energy transfer from the organic chromophore to the Eu^{3+} ion. Upon binding of the aza-18crown-6 moiety with a Cu^{2+} ion, pyridine is expected to coordinate with the Cu^{2+} ion, resulting in luminescence quenching. The europium emission should be recovered after the displacement of the Cu^{2+} ion upon copper sulphide precipitation.

Results and discussion

Synthesis and photophysical properties of L1 and EuL1

Ligand L1 was readily prepared from (4-iodopyridine-2,6-diyl) dimethanol (1)¹⁴ *via* a desymmetrization synthetic strategy. As shown in Scheme 1, a pyridine-containing chromophore (based on a D– π –A motif) was established *via* a Sonogashira cross-coupling reaction between 1 and 1-ethynyl-4-propoxybenzene (2).¹⁵ After converting both hydroxyl groups of 3 into the corresponding bromide, the aza-18-crown-6 and DO3A moieties were incorporated into 4 sequentially under basic conditions and afforded L1 in good yields. L1 was fully characterized using ¹H and ¹³C NMR spectroscopy and HRMS. Finally, acid hydrolysis of the *t*-butyl esters followed by Eu complex formation provided **EuL1**, which was characterized unambiguously using HRMS and HPLC (Table S1 and Fig. S1[†]).

In the UV-vis absorption spectrum, **L1** showed strong absorption bands at 235 and 310 nm in methanol which are attributed to the π to π^* transitions. The absorption bands were broadened and red-shifted in **EuL1** (245 and 333 nm, $\varepsilon_{333 \text{ nm}} = 7560 \text{ M}^{-1} \text{ cm}^{-1}$) in water (Fig. S2†). The excitation spectrum of **EuL1** at 615 nm showed maxima at 240 and 340 nm (Fig. S2†), evidencing an antenna effect due to energy transfer from the ligand to the Eu³⁺ ion. The ⁵D₀ \rightarrow ⁷F_J transitions of **EuL1** ($\lambda_{ex} = 325 \text{ nm}$) were found at 578 (J = 0), 585–603 (J = 1), 604–637 (J = 2), 646–658 (J = 3), and 673–712 nm (J = 4) in the emission spectrum (Fig. 2). The quantum yield of **EuL1** corresponding to the ⁵D₀ \rightarrow ⁷F₂ transitions of Eu³⁺ ions in water is 0.5% (Table S2†).

Fluorimetric titration studies of EuL1

With **EuL1** in hand, its binding properties towards Cu^{2+} ions were investigated. Upon the addition of 1 equiv. of Cu^{2+} ions (CuCl₂ as the source of Cu^{2+} ions), the absorption maximum of **EuL1** showed a slight red shift and the absorption ability slightly decreased due to the effect of the copper metal. In a titration study, **EuL1** exhibited a 17-fold quenching of the

Fig. 3 (a) Fluorimetric titration of EuL1 (10 μ M) towards Cu²⁺. The inset shows the plot of $I_0/(I - I_0)$ vs. [Cu²⁺] (0–20 μ M). *I* and I_0 stand for intensity of europium emission ${}^5D_0 \rightarrow {}^7F_2$. (b) Effects of various metal ions on the luminescence intensity of EuL1 (10 μ M). 1: EuL1 only; 2: Na⁺; 3: K⁺; 4: Ca²⁺; 5: Mg²⁺; 6: Ba²⁺; 7: Co²⁺; 8: Zn²⁺; 9: Ni²⁺; 10: Fe²⁺; 11: Mn²⁺; 12: Cu⁺; 13: Li⁺; 14: Cu²⁺; 15: all of the above metal ions except Cu²⁺. All spectra were acquired in water with excitation at 325 nm.

Fig. 4 The emission spectra of EuL1 (10 μ M) (red), with 1 equiv. of Cu²⁺ ions (green), and with 1 equiv. of Cu²⁺ ions and 1 equiv. of H₂S (black). All spectra were acquired in water with λ_{ex} at 325 nm.

europium emission with an excess of Cu²⁺ ions and the Benesi– Hildebrand plot showed a 1 : 1 binding stoichiometry with $K_{\rm B} =$ 1.2 × 10⁵ M⁻¹ (inset of Fig. 3a).¹⁶ The Job's plot also supported the formation of a **EuL1**–Cu²⁺ complex in a 1 : 1 ratio (Fig. S3[†]).

Fig. 5 (a) Fluorimetric titration of **EuL1**–Cu²⁺ (10 μ M, generated *in situ* with 2 equiv. of Cu²⁺) towards H₂S (0–100 μ M). The inset shows the plot of $I_0/(I - I_0)$ vs. [Na₂S] (0–100 μ M). *I* and I_0 stand for intensity of europium emission ⁵D₀ \rightarrow ⁷F₂. (b) Effects of various anions on the luminescence intensity of **EuL1** (10 μ M). 1: **EuL1** only; 2: Cl⁻; 3: SO₄²⁻; 4: HSO₄⁻; 5: I⁻; 6: CO₃²⁻; 7: HPO₄²⁻; 8: Br⁻; 9: HCO₃⁻; 10: S²⁻; 11: GSH; 12: cysteine. All spectra were acquired in water with excitation at 325 nm.

In a competitive study, the addition of a large excess of various metal ions, such as Na⁺, K⁺, Ca²⁺, Mg²⁺, Ba²⁺, Co²⁺, Zn²⁺, Ni²⁺, Fe²⁺, Mn²⁺, Cu⁺ and Li⁺ ions, to **EuL1** resulted in only slight luminescence changes (red columns in Fig. 3b). The subsequent addition of excess Cu²⁺ ions caused significant luminescence quenching (blue columns in Fig. 3b). These results indicate the high selectivity of **EuL1** towards Cu²⁺ ions and that the binding between **EuL1** and Cu²⁺ ions is not interfered by other metal ions. In a pH study, **EuL1** remains highly emissive and was quenched by Cu²⁺ ions in the pH range 6 to 8 (Fig. S4⁺), indicating that **EuL1** is stable and can bind to Cu²⁺ ions under physiological conditions.

To study the reversibility of the binding between EuL1 and Cu^{2+} ions, a small amount of H_2S (Na₂S as the source of H_2S) was added. The EuL1-Cu²⁺ complex responded instantaneously (requiring only 40 s to reach saturation without stirring or shaking) (Fig. S5[†]), and Eu emission resumed with a similar profile for the emission spectrum to that of EuL1 (Fig. 4). This result indicated that the DO3A-Eu³⁺ complex was not displaced by a Cu^{2+} ion, forming the **EuL1**- Cu^{2+} complex in the previous step. More interestingly, Eu emission was further enhanced (40-fold) with an excess of H_2S and the Eu^{3+} emission profile showed significant changes, suggesting binding between EuL1 and H₂S (Fig. 5a). The Benesi-Hildebrand plot showed a 1:1 binding stoichiometry with $K_{\rm B} = 1.5 \times 10^4 \ {\rm M}^{-1}$ (inset of Fig. 5a).¹⁶ The detection limit of EuL1 towards H₂S was calculated according to the $3S_{\rm D}$ /slope as low as 60 nM. Surprisingly, direct titration of EuL1 against H2S resulted in only about a 5fold luminescence enhancement with a non-linear relationship in the 1:1 Benesi-Hildebrand plot (Fig. 6). These results indicated that the Cu^{2+} ion facilitates the specific 1 : 1 binding of EuL1 and H₂S, presumably via pre-organizing the conformation of EuL1. On the other hand, non-specific binding (possibly a mixture of 1:1 and 2:1 binding) between EuL1 and H₂S resulted without the favourable conformation that is induced by

Fig. 6 Fluorimetric titration of **EuL1** (10 μ M) towards H₂S (0–300 μ M). The inset shows the plot of $I_0/(I - I_0)$ vs. [H₂S] (0–300 μ M). *I* and I_0 stand for intensity of europium emission ${}^5D_0 \rightarrow {}^7F_2$. All spectra were acquired in water with λ_{ex} at 325 nm.

Fig. 7 Top: proposed binding mechanism of EuL1 towards Cu²⁺ and H₂S (Na₂S as the source of H₂S). Bottom left: emission spectra of the Eu complexes ($\lambda_{ex} = 325$ nm). Bottom right: ¹H NMR spectra of the La complexes (6.5–8.5 ppm).

the pre-complexation of a Cu^{2+} ion. This proposal was further supported by the dramatic luminescence drop of the **EuL1**–Na₂S complex upon heating (>70 °C) (Fig. S6†). This type of Cu^{2+} assisted luminescence enhancement of Eu emission is unprecedented. In a competitive study, **EuL1**– Cu^{2+} showed insignificant changes in luminescence with a large excess of anions, including Cl⁻, SO₄²⁻, HSO₄⁻, I⁻, CO₃²⁻, HPO₄²⁻, Br⁻ and HCO₃⁻, and only small changes for GSH and cysteine (red columns in Fig. 5b). Upon the addition of H₂S, the Eu emissions were recovered in all the above cases, indicating a high selectivity of **EuL1**–Cu²⁺ towards H₂S.

Mechanistic studies

The binding mechanisms of EuL1 towards ${\rm Cu}^{2+}$ ions and the $EuL1{\rm -Cu}^{2+}$ complex towards H_2S were studied using

Table 1 The ratio of ${}^5D_0 \to {}^7F_J$ (J = 0 to 4) emission bands of EuL1, EuL1 + Cu^{2+} and EuL1 + Cu^{2+} + H_2S^a

^a All spectra were acquired in water with excitation at 325 nm.

a comparative analysis of the emission spectra of the Eu complexes and the ¹H NMR spectra of La complexes.¹⁷ As shown in Fig. 7, the profile of the emission spectrum of **EuL1** did not change significantly upon the addition of Cu^{2+} ions. Comparing [**EuL1**], [**EuL1** + Cu^{2+}] and [**EuL1** + Cu^{2+} + H₂S], measured under the same solution conditions, similar spectra were observed for [**EuL1**] and [**EuL1** + Cu^{2+}] (${}^5D_0 \rightarrow {}^7F_1 : {}^7F_2 : {}^7F_4$ of [**EuL1**] = 1 : 1.122 : 0.55 and ${}^5D_0 \rightarrow {}^7F_1 : {}^7F_2 : {}^7F_4$ [**EuL1** + Cu^{2+}] = 1 : 1.186 : 0.91, Table 1). This is correlated with the NMR data and shows that the Cu^{2+} ion is coordinated in the aza-crown. However, signal broadening was observed in the ¹H NMR spectrum of **LaL1**, indicating rapid metal-ligand exchange. These results suggested that the pyridine moiety of the organic chromophore is rapidly switching between the DO3A–Eu³⁺ and

Fig. 8 The structures of the negative control compounds EuL2, EuL3, L4 and L5.

Fig. 9 The emission spectra of negative control compounds (10 μ M) with various concentration of Cu²⁺ ions. (a): EuL2; (b): EuL3; (c): L4; (d): L5. All spectra were acquired in water with λ_{ex} at 325 nm.

aza-18-crown-6–Cu²⁺ complexes, causing significant luminescence quenching. Moreover, the binding of Cu²⁺ would also provide a favourable conformation for forming a new 1:1 complex with H₂S. Upon the addition of H₂S, the emission profile of **EuL1** changed significantly, $\Delta J = 2/\Delta J = 1$ for [**EuL1** + Cu²⁺ + H₂S],¹⁸ and the intensity ratio was about >200% higher for [**EuL1**] and [**EuL1** + Cu²⁺]. This increase can be attributed to the lower symmetry of the complexes with the addition of sulphide ions (Fig. 7) and the ¹H NMR signals of **LaL1** were sharpened. These results suggested new complex formation after the displacement of the Cu²⁺ ion *via* CuS precipitation. This proposal is further supported by the HRMS spectrum of the **EuL1**–Na₂S complex (Fig. S7†) and the change in the quantum yields (Table S2†). The **EuL1**–Na₂S complex is highly emissive probably due to its rigid structure.

The proposed binding mechanism was also examined using a series of negative control compounds (Fig. 8).¹⁹ **EuL2** showed no luminescence quenching upon the addition of Cu^{2+} ions (Fig. 9a). This result indicated that the carbonyl linker of aza-18crown-6 may be too rigid for coordination between Cu^{2+} and pyridine, which could be essential for Eu emission quenching. Without the aza-crown moiety, **EuL3** also showed no luminescence quenching towards Cu^{2+} (Fig. 9b), suggesting DO3A–Eu³⁺ is stable with Cu^{2+} and the aza-crown motif is important for the Cu^{2+} binding. **L4** bearing the pyridine-chromophore showed profound luminescence quenching, but its phenyl analogue (L5) showed no significant change in luminescence upon the addition of Cu^{2+} ions (Fig. 9c and d). These results indicated that the pyridine moiety of the chromophore is essential for the binding of Cu^{2+} to the aza-crown moiety. The results of this series of negative control compounds are in full agreement with the proposed mechanism in Fig. 7.

Conclusions

In summary, we have prepared a water-soluble and emissive Eucomplex (EuL1) based on a DO3A(Eu³⁺)–pyridine–aza-crown motif, and studied its consecutive binding properties towards Cu²⁺ and H₂S extensively. EuL1 binds to Cu²⁺ ions selectively ($K_B = 1.2 \times 10^5 \text{ M}^{-1}$) inducing 17-fold luminescence quenching and forming a 1 : 1 stoichiometric complex (EuL1–Cu²⁺), which responds to H₂S selectively with restoration of the original EuL1 emission followed by a further 40-fold luminescence enhancement and a nano-molar detection limit (60 nM). Mass spectroscopic analysis showed the formation of a 1 : 1 stoichiometric complex (EuL1–Na₂S) with $K_B = 1.5 \times 10^4 \text{ M}^{-1}$. Without Cu²⁺ ions, EuL1 shows non-specific binding towards H₂S with only a 5-fold luminescence enhancement. These results indicate that the Cu²⁺ ion may pre-organize the conformation of EuL1 and facilitate the formation of the EuL1–Na₂S complex. The studies

on this unprecedented Cu^{2+} -assisted luminescence enhancement of Eu emission are still ongoing. With long-lived Eu emission, reversible binding properties, an instantaneous response and high selectivity towards H₂S, this Eu-based luminescence "off–on" gate could find suitable applications for H₂S imaging in biological systems.
