# A smart "off-on" gate for the *in situ* detection of hydrogen sulphide with Cu(II)-assisted europium emission†

Zhenhao Liang,<sup>ab</sup> Tik-Hung Tsoi,<sup>b</sup> Chi-Fai Chan,<sup>c</sup> Lixiong Dai,<sup>bc</sup> Yudan Wu,<sup>a</sup> Guangyan Du,<sup>a</sup> Lizhi Zhu,<sup>ab</sup> Chi-Sing Lee,\*<sup>a</sup> Wing-Tak Wong,\*<sup>b</sup> Ga-Lai Law\*<sup>b</sup> and Ka-Leung Wong\*<sup>c</sup>

A water-soluble and emissive Eu-complex (EuL1) bearing a DO3A(Eu $^{3+}$ )-pyridine-aza-crown motif has been prepared and its Cu $^{2+}$  complex has been demonstrated to be a smart luminescence "off-on" gate for H<sub>2</sub>S detection in water with a nano-molar detection limit (60 nM). EuL1 binds to Cu $^{2+}$  ions selectively ( $K_B = 1.2 \times 10^5 \text{ M}^{-1}$ ) inducing 17-fold luminescence quenching and forming a 1:1 stoichiometric complex (EuL1-Cu $^{2+}$ ), which responds to H<sub>2</sub>S selectively with restoration of the original Eu emission of EuL1 followed by a further 40-fold luminescence enhancement, forming a 1:1 stoichiometric complex (EuL1-Na<sub>2</sub>S,  $K_B = 1.5 \times 10^4 \text{ M}^{-1}$ ). Without Cu $^{2+}$  ions, EuL1 showed non-specific binding towards H<sub>2</sub>S with only a 5-fold luminescence enhancement.

## Introduction

Hydrogen sulphide (H<sub>2</sub>S) is the smallest bioactive thiol that may act as a gaseous signalling agent,¹ and its production in different tissue types is associated with a wide range of physiological responses such as vascular smooth muscle relaxation,² mitochondrial ATP production,³ insulin-signalling inhibition,⁴ regulation of inflammation response⁵ and mediation of neurotransmission.⁶ Moreover, recent investigations show that abnormal levels of H<sub>2</sub>S are associated with a variety of diseases, such as neurodegenerative diseases,<sup>7</sup> diabetes⁶ and cancer.⁶ However, the biological targets of H<sub>2</sub>S and the mechanisms of these H<sub>2</sub>S-related physiological phenomena remain unclear. Therefore the development of responsive and reversible luminescence probes for non-invasive real time monitoring of H<sub>2</sub>S may be useful for understanding its biological modes of action.

One of the major approaches for developing luminescence H<sub>2</sub>S detection<sup>10</sup> is based on sulphide-specific chemical reactions, such as reduction of an azide<sup>11</sup> and nucleophilic addition of a sulphide ion.<sup>12</sup> This type of luminescence probe is generally irreversible and usually requires a considerably long incubation

As illustrated in Fig. 1, **EuL1** contains a DO3A–Eu<sup>3+</sup> complex and an aza-18-crown-6 moiety, which are linked to the 2- and 6-positions of a pyridine-containing chromophore constituting a switch-like structure. In the ground state, **EuL1** should be emissive due to the coordination of the pyridine chromophore

time. An alternative approach is based on CuS precipitation<sup>13</sup> due to the low-solubility of CuS ( $K_{\rm sp}=6.3\times10^{-36}$ ). These luminescence probes are generally reversible with low detection limits. We are particularly interested in developing H<sub>2</sub>S luminescence sensors based on organo-lanthanide complexes due to their water-solubility and unique photophysical properties, including line-like emission spectra and long luminescence lifetimes (micro to milli second scale) that can effectively separate the observing signal from biological autofluorescence noise and are suitable for time-gated detection. Recently, a few studies have been found in the literature with irreversible H<sub>2</sub>S lanthanide probes. Herein, we report the development of a novel responsive europium-based luminescence "off–on" gate for the *in situ* detection of H<sub>2</sub>S in water.

Chemical Science Edge Article

to a  $\mathrm{Eu}^{3+}$  ion, which favours energy transfer from the organic chromophore to the  $\mathrm{Eu}^{3+}$  ion. Upon binding of the aza-18-crown-6 moiety with a  $\mathrm{Cu}^{2+}$  ion, pyridine is expected to coordinate with the  $\mathrm{Cu}^{2+}$  ion, resulting in luminescence quenching. The europium emission should be recovered after the displacement of the  $\mathrm{Cu}^{2+}$  ion upon copper sulphide precipitation.

### Results and discussion

#### Synthesis and photophysical properties of L1 and EuL1

Ligand L1 was readily prepared from (4-iodopyridine-2,6-diyl) dimethanol (1)<sup>14</sup> *via* a desymmetrization synthetic strategy. As shown in Scheme 1, a pyridine-containing chromophore (based on a D- $\pi$ -A motif) was established *via* a Sonogashira crosscoupling reaction between 1 and 1-ethynyl-4-propoxybenzene (2).<sup>15</sup> After converting both hydroxyl groups of 3 into the corresponding bromide, the aza-18-crown-6 and DO3A moieties were incorporated into 4 sequentially under basic conditions and afforded L1 in good yields. L1 was fully characterized using <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy and HRMS. Finally, acid hydrolysis of the *t*-butyl esters followed by Eu complex formation provided EuL1, which was characterized unambiguously using HRMS and HPLC (Table S1 and Fig. S1†).

Scheme 1 Synthesis of L1 and EuL1.

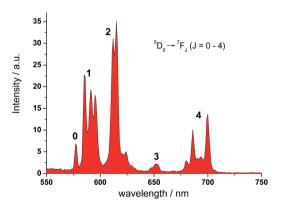

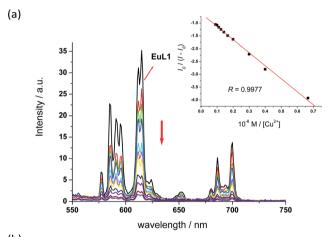

Fig. 2 Emission spectrum of EuL1 ( $H_2O$ ,  $\lambda_{ex} = 325$  nm,  $10~\mu M$ ).

In the UV-vis absorption spectrum, **L1** showed strong absorption bands at 235 and 310 nm in methanol which are attributed to the  $\pi$  to  $\pi^*$  transitions. The absorption bands were broadened and red-shifted in **EuL1** (245 and 333 nm,  $\varepsilon_{333~\rm nm}=7560~\rm M^{-1}~cm^{-1})$  in water (Fig. S2†). The excitation spectrum of **EuL1** at 615 nm showed maxima at 240 and 340 nm (Fig. S2†), evidencing an antenna effect due to energy transfer from the ligand to the Eu<sup>3+</sup> ion. The  $^5{\rm D}_0 \rightarrow ^7{\rm F}_J$  transitions of **EuL1** ( $\lambda_{\rm ex}=325~\rm nm$ ) were found at 578 (J=0), 585–603 (J=1), 604–637 (J=2), 646–658 (J=3), and 673–712 nm (J=4) in the emission spectrum (Fig. 2). The quantum yield of **EuL1** corresponding to the  $^5{\rm D}_0 \rightarrow ^7{\rm F}_2$  transitions of Eu<sup>3+</sup> ions in water is 0.5% (Table S2†).

#### Fluorimetric titration studies of EuL1

With **EuL1** in hand, its binding properties towards Cu<sup>2+</sup> ions were investigated. Upon the addition of 1 equiv. of Cu<sup>2+</sup> ions (CuCl<sub>2</sub> as the source of Cu<sup>2+</sup> ions), the absorption maximum of **EuL1** showed a slight red shift and the absorption ability slightly decreased due to the effect of the copper metal. In a titration study, **EuL1** exhibited a 17-fold quenching of the

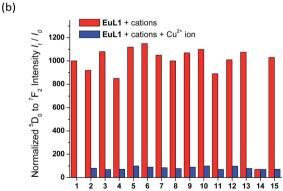

Fig. 3 (a) Fluorimetric titration of EuL1 (10  $\mu$ M) towards Cu<sup>2+</sup>. The inset shows the plot of  $I_0/(I-I_0)$  vs. [Cu<sup>2+</sup>] (0–20  $\mu$ M). I and  $I_0$  stand for intensity of europium emission  $^5D_0 \rightarrow ^7F_2$ . (b) Effects of various metal ions on the luminescence intensity of EuL1 (10  $\mu$ M). 1: EuL1 only; 2: Na<sup>+</sup>; 3: K<sup>+</sup>; 4: Ca<sup>2+</sup>; 5: Mg<sup>2+</sup>; 6: Ba<sup>2+</sup>; 7: Co<sup>2+</sup>; 8: Zn<sup>2+</sup>; 9: Ni<sup>2+</sup>; 10: Fe<sup>2+</sup>; 11: Mn<sup>2+</sup>; 12: Cu<sup>+</sup>; 13: Li<sup>+</sup>; 14: Cu<sup>2+</sup>; 15: all of the above metal ions except Cu<sup>2+</sup>. All spectra were acquired in water with excitation at 325 nm.

**Edge Article** 

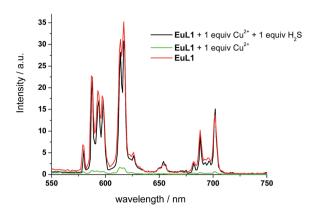

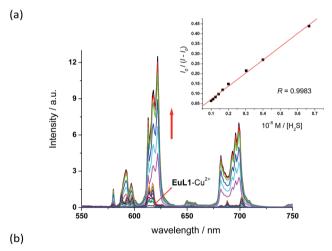

Fig. 4 The emission spectra of EuL1 (10  $\mu$ M) (red), with 1 equiv. of Cu<sup>2+</sup> ions (green), and with 1 equiv. of Cu<sup>2+</sup> ions and 1 equiv. of H<sub>2</sub>S (black). All spectra were acquired in water with  $\lambda_{ex}$  at 325 nm.

europium emission with an excess of  $\text{Cu}^{2+}$  ions and the Benesi-Hildebrand plot showed a 1 : 1 binding stoichiometry with  $K_{\text{B}} = 1.2 \times 10^5 \text{ M}^{-1}$  (inset of Fig. 3a). The Job's plot also supported the formation of a **EuL1**-Cu<sup>2+</sup> complex in a 1 : 1 ratio (Fig. S3†).

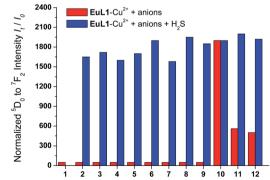

Fig. 5 (a) Fluorimetric titration of EuL1–Cu²+ (10  $\mu$ M, generated *in situ* with 2 equiv. of Cu²+) towards H<sub>2</sub>S (0–100  $\mu$ M). The inset shows the plot of  $I_0/(I-I_0)$  vs. [Na<sub>2</sub>S] (0–100  $\mu$ M). I and  $I_0$  stand for intensity of europium emission  $^5D_0 \rightarrow ^7F_2$ . (b) Effects of various anions on the luminescence intensity of EuL1 (10  $\mu$ M). 1: EuL1 only; 2: Cl¯; 3: SO<sub>4</sub>²−; 4: HSO<sub>4</sub>¬; 5: I¬; 6: CO<sub>3</sub>²−; 7: HPO<sub>4</sub>²−; 8: Br¬; 9: HCO<sub>3</sub>¬; 10: S²−; 11: GSH; 12: cysteine. All spectra were acquired in water with excitation at 325 nm.

In a competitive study, the addition of a large excess of various metal ions, such as Na $^+$ , K $^+$ , Ca $^{2+}$ , Mg $^{2+}$ , Ba $^{2+}$ , Co $^{2+}$ , Zn $^{2+}$ , Ni $^{2+}$ , Fe $^{2+}$ , Mn $^{2+}$ , Cu $^+$  and Li $^+$  ions, to **EuL1** resulted in only slight luminescence changes (red columns in Fig. 3b). The subsequent addition of excess Cu $^{2+}$  ions caused significant luminescence quenching (blue columns in Fig. 3b). These results indicate the high selectivity of **EuL1** towards Cu $^{2+}$  ions and that the binding between **EuL1** and Cu $^{2+}$  ions is not interfered by other metal ions. In a pH study, **EuL1** remains highly emissive and was quenched by Cu $^{2+}$  ions in the pH range 6 to 8 (Fig. S4 $^+$ ), indicating that **EuL1** is stable and can bind to Cu $^{2+}$  ions under physiological conditions.

To study the reversibility of the binding between EuL1 and Cu<sup>2+</sup> ions, a small amount of H<sub>2</sub>S (Na<sub>2</sub>S as the source of H<sub>2</sub>S) was added. The EuL1-Cu<sup>2+</sup> complex responded instantaneously (requiring only 40 s to reach saturation without stirring or shaking) (Fig. S5†), and Eu emission resumed with a similar profile for the emission spectrum to that of EuL1 (Fig. 4). This result indicated that the DO3A-Eu<sup>3+</sup> complex was not displaced by a Cu<sup>2+</sup> ion, forming the **EuL1**-Cu<sup>2+</sup> complex in the previous step. More interestingly, Eu emission was further enhanced (40-fold) with an excess of H<sub>2</sub>S and the Eu<sup>3+</sup> emission profile showed significant changes, suggesting binding between EuL1 and H<sub>2</sub>S (Fig. 5a). The Benesi-Hildebrand plot showed a 1:1 binding stoichiometry with  $K_{\rm B}=1.5\times10^4~{\rm M}^{-1}$  (inset of Fig. 5a).16 The detection limit of EuL1 towards H2S was calculated according to the  $3S_D$ /slope as low as 60 nM. Surprisingly, direct titration of EuL1 against H2S resulted in only about a 5fold luminescence enhancement with a non-linear relationship in the 1:1 Benesi-Hildebrand plot (Fig. 6). These results indicated that the Cu<sup>2+</sup> ion facilitates the specific 1:1 binding of EuL1 and H<sub>2</sub>S, presumably via pre-organizing the conformation of EuL1. On the other hand, non-specific binding (possibly a mixture of 1:1 and 2:1 binding) between EuL1 and H2S resulted without the favourable conformation that is induced by

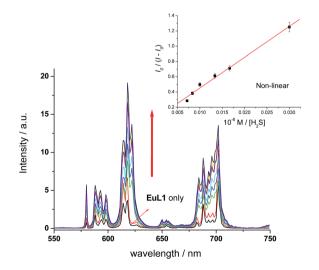

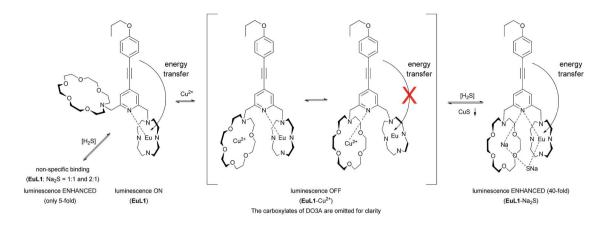

Fig. 6 Fluorimetric titration of EuL1 (10  $\mu$ M) towards H<sub>2</sub>S (0–300  $\mu$ M). The inset shows the plot of  $I_0/(I-I_0)$  vs. [H<sub>2</sub>S] (0–300  $\mu$ M). I and  $I_0$  stand for intensity of europium emission  $^5D_0 \rightarrow ^7F_2$ . All spectra were acquired in water with  $\lambda_{\rm ex}$  at 325 nm.

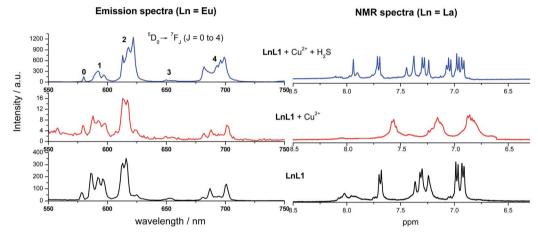

Fig. 7 Top: proposed binding mechanism of EuL1 towards  $Cu^{2+}$  and  $H_2S$  ( $Na_2S$  as the source of  $H_2S$ ). Bottom left: emission spectra of the Eu complexes ( $\lambda_{ex} = 325$  nm). Bottom right:  $^1H$  NMR spectra of the La complexes (6.5-8.5 ppm).

the pre-complexation of a  $\mathrm{Cu}^{2^+}$  ion. This proposal was further supported by the dramatic luminescence drop of the  $\mathrm{EuL1}\text{-Na}_2\mathrm{S}$  complex upon heating (>70 °C) (Fig. S6†). This type of  $\mathrm{Cu}^{2^+}$ -assisted luminescence enhancement of Eu emission is unprecedented. In a competitive study,  $\mathrm{EuL1}\text{-Cu}^{2^+}$  showed insignificant changes in luminescence with a large excess of anions, including  $\mathrm{Cl}^-$ ,  $\mathrm{SO_4}^{2^-}$ ,  $\mathrm{HSO_4}^-$ ,  $\mathrm{I}^-$ ,  $\mathrm{CO_3}^{2^-}$ ,  $\mathrm{HPO_4}^{2^-}$ ,  $\mathrm{Br}^-$  and  $\mathrm{HCO_3}^-$ , and only small changes for GSH and cysteine (red columns in Fig. 5b). Upon the addition of  $\mathrm{H_2S}$ , the Eu emissions were recovered in all the above cases, indicating a high selectivity of  $\mathrm{EuL1}\text{-Cu}^{2^+}$  towards  $\mathrm{H_2S}$ .

#### Mechanistic studies

The binding mechanisms of EuL1 towards  $Cu^{2+}$  ions and the EuL1- $Cu^{2+}$  complex towards  $H_2S$  were studied using

Table 1 The ratio of  $^5D_0 \rightarrow ^7F_J$  (J=0 to 4) emission bands of EuL1, EuL1 + Cu<sup>2+</sup> and EuL1 + Cu<sup>2+</sup> + H<sub>2</sub>S<sup>a</sup>

$^{5}D_{0} \rightarrow$	$^{7}F_{0}$	$^{7}F_{1}$	$^{7}\mathrm{F}_{2}$	$^{7}\mathrm{F}_{3}$	$^{7}\mathrm{F}_{4}$
EuL1 EuL1 + Cu <sup>2+</sup>	0.01 0.08	1	1.22 1.86	0.08 0.15	0.55 0.91
$EuL1 + Cu^{2+} + H_2S$	0.48	1	3.98	0.15	1.95

<sup>&</sup>lt;sup>a</sup> All spectra were acquired in water with excitation at 325 nm.

a comparative analysis of the emission spectra of the Eu complexes and the  $^1H$  NMR spectra of La complexes. $^{17}$  As shown in Fig. 7, the profile of the emission spectrum of EuL1 did not change significantly upon the addition of  $Cu^{2+}$  ions. Comparing [EuL1], [EuL1 +  $Cu^{2+}$ ] and [EuL1 +  $Cu^{2+}$  +  $H_2S$ ], measured under the same solution conditions, similar spectra were observed for [EuL1] and [EuL1 +  $Cu^{2+}$ ] ( $^5D_0 \rightarrow ^7F_1: ^7F_2: ^7F_4$  of [EuL1] = 1:1.122:0.55 and  $^5D_0 \rightarrow ^7F_1: ^7F_2: ^7F_4$  [EuL1 +  $Cu^{2+}$ ] = 1:1.186:0.91, Table 1). This is correlated with the NMR data and shows that the  $Cu^{2+}$  ion is coordinated in the aza-crown. However, signal broadening was observed in the  $^1H$  NMR spectrum of LaL1, indicating rapid metal-ligand exchange. These results suggested that the pyridine moiety of the organic chromophore is rapidly switching between the DO3A–Eu $^{3+}$  and

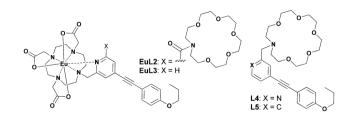

Fig. 8 The structures of the negative control compounds EuL2, EuL3, L4 and L5.

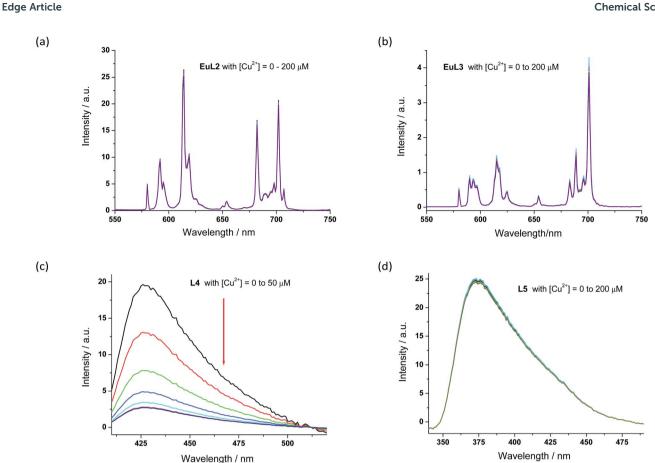

Fig. 9 The emission spectra of negative control compounds (10  $\mu$ M) with various concentration of Cu<sup>2+</sup> ions. (a): EuL2; (b): EuL3; (c): L4; (d): L5. All spectra were acquired in water with  $\lambda_{ex}$  at 325 nm.

aza-18-crown-6-Cu2+ complexes, causing significant luminescence quenching. Moreover, the binding of Cu<sup>2+</sup> would also provide a favourable conformation for forming a new 1:1 complex with H2S. Upon the addition of H2S, the emission profile of EuL1 changed significantly,  $\Delta J = 2/\Delta J = 1$  for [EuL1 + Cu<sup>2+</sup> + H<sub>2</sub>S], <sup>18</sup> and the intensity ratio was about >200% higher for [EuL1] and [EuL1 + Cu<sup>2+</sup>]. This increase can be attributed to the lower symmetry of the complexes with the addition of sulphide ions (Fig. 7) and the <sup>1</sup>H NMR signals of LaL1 were sharpened. These results suggested new complex formation after the displacement of the Cu<sup>2+</sup> ion via CuS precipitation. This proposal is further supported by the HRMS spectrum of the EuL1-Na<sub>2</sub>S complex (Fig. S7†) and the change in the quantum yields (Table S2†). The EuL1-Na<sub>2</sub>S complex is highly emissive probably due to its rigid structure.

The proposed binding mechanism was also examined using a series of negative control compounds (Fig. 8).19 EuL2 showed no luminescence quenching upon the addition of Cu<sup>2+</sup> ions (Fig. 9a). This result indicated that the carbonyl linker of aza-18crown-6 may be too rigid for coordination between Cu<sup>2+</sup> and pyridine, which could be essential for Eu emission quenching. Without the aza-crown moiety, EuL3 also showed no luminescence quenching towards Cu<sup>2+</sup> (Fig. 9b), suggesting DO3A-Eu<sup>3+</sup> is stable with Cu<sup>2+</sup> and the aza-crown motif is important for the Cu<sup>2+</sup> binding. L4 bearing the pyridine-chromophore showed

profound luminescence quenching, but its phenyl analogue (L5) showed no significant change in luminescence upon the addition of Cu<sup>2+</sup> ions (Fig. 9c and d). These results indicated that the pyridine moiety of the chromophore is essential for the binding of Cu2+ to the aza-crown moiety. The results of this series of negative control compounds are in full agreement with the proposed mechanism in Fig. 7.

## Conclusions

In summary, we have prepared a water-soluble and emissive Eucomplex (EuL1) based on a DO3A(Eu3+)-pyridine-aza-crown motif, and studied its consecutive binding properties towards Cu<sup>2+</sup> and H<sub>2</sub>S extensively. **EuL1** binds to Cu<sup>2+</sup> ions selectively  $(K_{
m B} = 1.2 imes 10^5 \, {
m M}^{-1})$  inducing 17-fold luminescence quenching and forming a 1: 1 stoichiometric complex (EuL1-Cu<sup>2+</sup>), which responds to H2S selectively with restoration of the original EuL1 emission followed by a further 40-fold luminescence enhancement and a nano-molar detection limit (60 nM). Mass spectroscopic analysis showed the formation of a 1:1 stoichiometric complex (EuL1-Na<sub>2</sub>S) with  $K_B = 1.5 \times 10^4 \text{ M}^{-1}$ . Without Cu<sup>2+</sup> ions, EuL1 shows non-specific binding towards H2S with only a 5-fold luminescence enhancement. These results indicate that the Cu<sup>2+</sup> ion may pre-organize the conformation of EuL1 and facilitate the formation of the EuL1-Na<sub>2</sub>S complex. The studies on this unprecedented  $\text{Cu}^{2+}$ -assisted luminescence enhancement of Eu emission are still ongoing. With long-lived Eu emission, reversible binding properties, an instantaneous response and high selectivity towards  $\text{H}_2\text{S}$ , this Eu-based luminescence "off-on" gate could find suitable applications for
