A multi-dimensional quasi-zeolite with $12 \times 10 \times 7$-ring channels demonstrates high thermal stability and good gas adsorption selectivity†

Jie Liang, Wei Xia, Junliang Sun, Jie Su, Maofeng Dou, Ruqiang Zou, Fuhui Liao, Yingxia Wang and Jianhua Lin

A novel quasi-zeolite PKU-15, with a rare 3-dimensional structure containing interconnected large (12-ring), medium (10-ring) and small (7-ring) multi-pore channels, was hydrothermally synthesised and characterised. A unique tri-bridging O$^{2-}$ ion is found to be encapsulated in the cage-like (Ge,Si)$_2$O$_{11}$ building unit and energetically stabilises the PKU-15 framework. The removal of this oxygen atom would convert PKU-15 into a hypothetical zeolite PKU-15H. Thus, PKU-15 can be considered as a unique ‘quasi-zeolite’, which bridges porous germanates and zeolites. Owing to the absence of terminal Ge–OH groups in its structure, PKU-15 shows a remarkably high thermal stability of up to 600 °C. PKU-15 is also the first microporous germanate that exhibits permanent porosity, with a BET area of 428 m$^2$ g$^{-1}$ and a good adsorption affinity toward CO$_2$.

Introduction

Zeolites, typically having a 3-dimensional (3D), 4-connected framework built from vertex-sharing TO$_4$ tetrahedra ($T = $ Si, Al, Ge, etc.), are crystalline porous materials with well-defined pores of molecular dimensions. Owing to their tunable pore systems, these materials have been widely used in catalysis, gas separation, and ion-exchange. Multi-pore zeolites with interconnected channels of different sizes are particularly important, as they allow the preferential diffusion of reactants and products through different channels when they are used as catalysts. About 40 multi-pore zeolite frameworks have been found; however, only one of them (ITQ-22) has a 3D structure containing fully interconnected channels with small (8-ring), medium (10-ring), and large (12-ring) pores. With this unique pore architecture, ITQ-22 shows a higher selectivity in the synthesis of ethylbenzene and cumene by the alkylation of benzene with ethanol and 2-propanol, respectively, as compared with ZSM-5 (10$^5$-$^6$ $^4$) cages of the zeolite framework is substantial. On the one hand, extra-framework anions encapsulated inside the small cages, during the process. Generally, these anions can be removed together with organic templates during calcination. But in some cases, the interactions between OH$^-$ /F$^-$ and the T atoms are so strong that these anions can become part of the framework as terminal groups and/or bridging species, for instance in the gallophosphate Mu-28, the AFR-type aluminophosphate (AlPO$_4$-40), the SFO-type aluminophosphate (SSZ-51) and the ZON-type gallophosphate (DAB-2). The effect of extra-framework anions encapsulated inside the small cages of the zeolite framework is substantial. On the one hand, these anions make their adjacent T atoms 5- or 6-coordinated, resulting in the porous compounds becoming ‘quasi-zeolites’. On the other hand, theoretical calculations reveal that the inclusion of OH$^-$ and F$^-$ in the small building units may provide additional stabilisation energy for the formation of as-made zeolites. Although the occlusion of OH$^-$ or F$^-$ in zeolite cages is common, little is known regarding the effect of O$^{2-}$ anions encapsulated inside similar cages on the structures of zeolites. Herein we report the first example of a quasi-zeolite |(CH$_3$)$_3$N(C$_3$H$_7$)$_2$|$_2$(Ge$_{10.75}$Si$_{1.25}$O$_{19}$O$_{12}$)[Ge$_3$O$_3$O$_6$] (denoted as PKU-15) with a unique tri-bridging O$^{2-}$ anion encapsulated within the cage-like (Si$_3$Ge$_2$)$_2$O$_{11}$ building unit. The interaction between the trapped O$^{2-}$ anion and the PKU-15 framework was also investigated by theoretical calculations. PKU-15 represents...
a unique fully interconnected multi-pore system with large (12-ring), medium (10-ring), and small (7-ring) channels. Its thermal stability and gas adsorption properties were also investigated.

Results and discussion

PKU-15 was hydrothermally synthesised by using trimethylpropylammonium hydroxide (Me$_3$PrN’OH$^-$) as the structure-directing agent (SDA). A single crystal with the size 280 × 40 × 20 μm$^3$ was selected for X-ray diffraction studies (Fig. S1†). The phase purity was confirmed by the agreement between the experimental powder X-ray diffraction pattern and the simulated one based on the single crystal X-ray diffraction results (Fig. S2†).

PKU-15 crystallizes in the orthorhombic space group Pnma (no. 62) with the lattice constants $a = 16.8108(5)$ Å, $b = 19.7138(7)$ Å and $c = 23.9394(9)$ Å. The framework is built from a novel (Ge,Si)$_{12}$O$_{31}$ cluster and GeO$_3$ 3-ring units. The 3-ring unit is rare in silicates, but is relatively common in germanates due to the favourable bond parameters of [GeO$_4$] units.$^{22}$ The (Ge,Si)$_{12}$O$_{31}$ cluster, consisting of three GeO$_5$ trigonal bipyramids and nine (Ge,Si)O$_4$ tetrahedra, is a novel building unit (BU) which has never been reported before (Fig. 1a). In each (Ge,Si)$_{12}$O$_{31}$ cluster, an oxygen anion is encapsulated within the BU and linked to three Ge atoms (Ge1, Ge2 and Ge3), making them 5- rather than 4-coordinated, with a trigonal bipyramidal geometry. This produces a Ge$_3$O$_7$ trimer in the centre of the cluster (Fig. 1b). Nine (Ge,Si)O$_4$ tetrahedra are then connected to the trimer through corner-sharing oxygen atoms, giving rise to the non-centrosymmetric (Ge,Si)$_{12}$O$_{31}$ cluster [simplified as (Ge,Si)$_{12}$ hereafter].

The PKU-15 framework can be described as (Ge,Si)$_{12}$O$_{25}$ layers interconnected by GeO$_3$ 3-rings (Fig. 2). The (Ge,Si)$_{12}$O$_{25}$ layer is formed solely by (Ge,Si)$_{12}$ clusters, where one (Ge,Si)$_{12}$ cluster connects to two neighbouring clusters by sharing a pair of oxygen vertices along the $a$-axis, and to another two clusters by sharing one corner of the tetrahedron along the $b$-axis. Such a connection gives rise to the (Ge,Si)$_{12}$O$_{25}$ layer with elliptical 10-ring holes in the $ab$-plane (Fig. 2a). Neighbouring (Ge,Si)$_{12}$O$_{25}$ layers, related by an $a$-glide normal to the $c$-axis, are then linked via GeO$_3$ 3-rings, forming the 3D framework of PKU-15 (Fig. 2b and c). The PKU-15 framework can be sketched as a 4,8-heterocoordinated sqc21 net (Fig. 2d), in which the (Ge,Si)$_{12}$ cluster shares all its 12 corners and acts as an 8-linkage node, and the GeO$_3$ 3-ring acts as a 4-linkage knot. This also results in a 3D interconnected channel system in PKU-15. A 12-ring sinusoidal channel with an opening of 3.7 Å × 8.7 Å runs along the $a$-axis, a 7-ring (2.3 Å × 4.0 Å) channel runs along the $b$-axis, and a 10-ring channel (4.0 Å × 6.1 Å) runs along the $c$-axis, assuming that the van der Waals radius is 1.35 Å for oxygen (Fig. S3 and S4†). Note that, unlike the circular 12-ring pores in other zeolite frameworks, the 12-ring pore window in PKU-15 is rather squashed. This, combined with the unique 3D 12 × 10 × 7-ring multi-pore channel system, makes PKU-15 a potential catalyst candidate in the petrochemical industry.

The most interesting structural feature of PKU-15 is the presence of the tri-coordinated oxygen atom (O26) within the cage-like (Ge,Si)$_{12}$ cluster. The removal of O26 could transform PKU-15 into a hypothetical zeolite framework (denoted as PKU-15H), and the (Ge,Si)$_{12}$ cluster could be described by a hypothetical zeolitic -4-4-4- BU, which is transformed from the known 4-4- BU by inserting a third 4-ring in the middle (Fig. 3a and b). The structure of PKU-15H can be illustrated with the aid of the ZON framework, which is solely built from the 4-4- BU.$^{36,33-36}$ Similar to the connection mode of the 4-4- BU in ZON, neighbouring -4-4-4- BUs in the PKU-15H framework are joined in a ‘head to tail’ fashion to form chains running parallel to the $a$-axis (Fig. 3c and e). The adjacent chains, related by inversion

**Fig. 3** (a) -4-4-4- BU and (b) -3-4-3- BU. The most interesting structural feature of PKU-15 is the presence of the tri-coordinated oxygen atom (O26) within the cage-like (Ge,Si)$_{12}$ cluster. The removal of O26 could transform PKU-15 into a hypothetical zeolite framework (denoted as PKU-15H), and the (Ge,Si)$_{12}$ cluster could be described by a hypothetical zeolitic -4-4-4- BU, which is transformed from the known 4-4- BU by inserting a third 4-ring in the middle (Fig. 3a and b). The structure of PKU-15H can be illustrated with the aid of the ZON framework, which is solely built from the 4-4- BU.$^{36,33-36}$ Similar to the connection mode of the 4-4- BU in ZON, neighbouring -4-4-4- BUs in the PKU-15H framework are joined in a ‘head to tail’ fashion to form chains running parallel to the $a$-axis (Fig. 3c and e). The adjacent chains, related by inversion
substituting Ge\(^{4+}\) with Al\(^{3+}\), the tri-bridging oxygen anion may that, by introducing negative charges in the framework, such as other anions, such as F\(^{-}\), are crosslinked whereas they are crosslinked from the cages, as compared with the F\(^{-}\) anion in UiO-7. Thus, it may be more di

However, in the zirconium-phosphate analogue of ZON (ZAPO-M1), no similar bridging position is found. This hints that, by introducing negative charges in the framework, such as substituting Ge\(^{4+}\) with Al\(^{3+}\), the tri-bridging oxygen anion may be removed from the framework and realize the transformation from PKU-15 into PKU-15H. Related work is being studied.

As mentioned above, the tri-coordinated oxygen atom makes PKU-15 a quasi-zeolite. To further understand its role in the formation of the PKU-15 framework, we performed total energy calculations for PKU-15 and PKU-15H based on first-principles. The two systems were set in the same unit cell, and the only difference is the absence of the tri-coordinated O\(^{2-}\) atom in PKU-15H (see Experimental section). To investigate the role that other anions, such as F\(^{-}\), play in the framework formation, similar calculations were also performed for UiO-7 and UiO-7 without the di-bridging F atom (denoted as UiO-7H). As expected, the calculated energies for PKU-15 and UiO-7 are about 3.77 eV and 2.2 eV lower than those for PKU-15H and UiO-7H, respectively, suggesting that the extra-framework anions (O\(^{2-}\) and F\(^{-}\)) do provide additional stabilisation for the frameworks. The much larger energy difference in the PKU-15 system than in the UiO-7 system may suggest that the O\(^{2-}\) anion is more crucial for the formation of PKU-15 than the F\(^{-}\) anion for the formation of UiO-7. Thus, it may be more difficult to release O\(^{2-}\) anions from the cages, as compared with the F\(^{-}\) species. As indicated in the literature, the F\(^{-}\) anions in UiO-7 can be removed by calcination at approximately 450–550 °C;\(^\text{15}\) however, in our calculations, the O\(^{2-}\) anions can only escape from the -4-4-4-cages in PKU-15 when the heating temperature reaches 1000 °C. Since the PKU-15 framework will collapse at 600 °C due to the breaking of other Ge–O bonds, we cannot obtain the PKU-15 framework without the tri-coordinated O\(^{2-}\) atom by direct heating.

Except for the tri-coordinated O\(^{2-}\) atom, all the other oxygen atoms in PKU-15 are shared by two neighbouring germanium atoms; thus, there is no terminal group in the PKU-15 framework. As is known, –OH terminal groups are a common feature of porous germanates and can induce a condensation process which may cause the collapse of the framework during heating.\(^\text{38,39}\) Thus, it is expected that the absence of terminal –OH groups may endow PKU-15 with a high thermal stability. This is proved by TG analysis and in situ variable-temperature powder X-ray diffraction (Fig. 4). In the TG curve, the weight loss of 11.7 wt% (calcld 11.8 wt%) in the range between 200 °C and 700 °C is attributed to the removal of organic templates (Fig. 4a). A main endothermic peak at approximately 450 °C is also observed in the DSC curve, owing to SDA removal (Fig. 4a). As evidenced by the in situ variable-temperature powder X-ray diffraction data, PKU-15 retains its framework integrity up to about 600 °C, even after guest removal (Fig. 4b). The thermal stability of PKU-15 is among the highest reported for porous germanates, and is even
higher than some germanate-based zeolites, such as SU-16,40 PKU-9,41 GaGe-JU-64,42 and PKU-14.43

Four half-occupied [(CH₃)₃N(C₃H₇)]⁺ (shortened to Me₃PrN⁺) cations are located in the 12- and 10-ring channels to compensate the −2 charge of the PKU-15 framework (Fig. S5†). Unlike other germanates that usually undergo structure collapse during the removal of organic species, the Me₃PrN⁺ cations in PKU-15 can be totally removed while keeping the framework integrity after heating in ozone for 6 hours (Fig. S6†). Thus, the porosity of the germanate-based PKU-15 quasi-zeolite can be characterised. The N₂ sorption isotherms of the ozone-treated sample at 77 K exhibit a typical type-I behavior, indicating the microporous features of PKU-15 (Fig. 5a). The BET area is 428 m² g⁻¹, compared with about 750 m² g⁻¹ for a silicate analogue. At 273 K, the ozone-treated PKU-15 sample can adsorb a large amount of CO₂ (1.0 mmol g⁻¹, 22.6 cm³ g⁻¹) at 1.0 bar (Fig. 5b). This value is lower than that of the ‘benchmark’ 13X zeolite (7.06 mmol g⁻¹),44 but is higher than that of our recently reported mesoporous germanate PKU-17 (0.7 mmol g⁻¹).45 In light of the unique channel system in PKU-15, we further tested its selective gas adsorption properties. In addition to the CO₂ adsorption measurements, CH₄, C₂H₆, and N₂ adsorption studies were also carried out at 273 K. As expected, PKU-15 can adsorb a moderate amount of CH₄ (0.5 mmol g⁻¹, 11.3 cm³ g⁻¹), slightly lower amounts of C₂H₄ (0.32 mmol g⁻¹, 7.3 cm³ g⁻¹) and N₂ (0.28 mmol g⁻¹, 6.3 cm³ g⁻¹), and a limited amount of C₂H₆ (0.18 mmol g⁻¹, 4.2 cm³ g⁻¹). In view of the kinetic diameters of 3.3 Å for CO₂, 3.6 Å for CH₄, 3.8 Å for N₂, 4.2 Å for C₂H₄, and 4.4 Å for C₂H₆, it can be inferred that the pore openings in PKU-15 should be approximately 3.8–4.2 Å in diameter. This is consistent with the crystallographically observed aperture size of 3.7 Å × 8.7 Å for PKU-15. The adsorption selectivity for CO₂ over other gases shown by PKU-15 may have applications in the separation of CO₂ from flue-gas streams and the separation of CO₂ from hydrocarbons.

**Conclusions**

In summary, a novel silicogermanate quasi-zeolite PKU-15 with 3D 12 × 10 × 7-ring multi-pore channels was synthesised by using Me₃PrN⁺OH⁻ as the SDA. The framework of PKU-15 is built from two BUs, the known Ge₃O₉ 3-ring unit and a new (Ge,Si)₁₂O₃₁ cluster, which are arranged in a 4,8-heterocoordinated sqc21 net. Without any terminal –OH groups, PKU-15 shows a high thermal stability of up to 600 °C. It also shows a good affinity towards CO₂. For the first time, a tri-coordinated oxygen anion is found to be encapsulated in the cage-like (Ge,Si)₁₂O₃₁ cluster and provides a high additional stabilisation energy for the framework. The successful removal of the O³⁻ anion would transform PKU-15 into a hypothetical zeolite PKU-15H. Thus, the discovery of the quasi-zeolite PKU-15 may build a bridge between porous germanates and zeolites.

**Experimental section**

**Synthesis**

Certain amounts of amorphous SiO₂ and GeO₂ were mixed with Me₃PrN⁺OH⁻ solution, and the mixture was stirred until a uniform suspension was formed. The composition of the initial gel was 0.1SiO₂ : 0.9GeO₂ : 0.5Me₃PrN⁺OH⁻ : xH₂O, x = 3–7. The mixture was transferred into a Teflon-lined stainless steel autoclave and heated at 175 °C for 14 days. The colourless single crystals were filtered, washed with ethanol, and then dried at 60 °C overnight. The sample was calcined at 200 °C in O₃ for 6 hours to remove the organic species in the channels.

**Structure determination**

A suitable single crystal of PKU-15 with dimensions of 280 × 40 × 20 μm³ was selected for single crystal X-ray diffraction measurements. Data were collected on a Supernova diffractometer with graphite-monochromated MoKα radiation (λ = 0.71073 Å) at 100 K. Data reduction and numerical absorption correction were applied using CrysAlisPro. The structure was solved by using direct methods and refined on F² using the full-matrix least-squares technique with the SHELX program.46,47 The structure of PKU-15 is orthorhombic and contains 15 unique T (T = Ge, Si) atoms in an asymmetric unit. The three 5-coordinated T-atoms and the three 4-coordinated T-atoms related to the 3-rings were refined as Ge atoms. After one round, the T atom with a Ge occupancy of more than 1.0 was also refined as Ge. In the remaining eight 4-coordinated positions, Ge and Si were randomly distributed with occupancies ranging from 0 to 1.
from 0.849 to 0.982 for Ge and 0.018 to 0.151 for Si. All nonhydrogen atom positions except carbon were refined anisotropically. The carbon chains were refined with restraints, fixing the C–C and N–C distances. Hydrogen atoms in the SDA were introduced in the ideal positions as riding on their bonded atoms and were assigned isotropic thermal parameters 1.2 and 1.5 times those of the bonded C atoms. The crystallographic data and structure refinement results are summarised in Table S1.† CCDC 1059012 contains the supplementary crystallographic data for this paper.

Computing method

Our first-principles calculations were carried out with density functional theory (DFT) as implemented in the Vienna Ab Initio Simulation Package (VASP).36,37 The calculations were performed based on the projector augmented wave (PAW) method with plane-wave cutoff energy of 400 eV.36,37 The exchange-correlation potential was described using Perdew–Burke–Ernzerhof (PBE).38 The Brillouin-zone integration was performed with a $2 \times 2 \times 2$ Monkhorst-Pack $k$-mesh. Owing to the large numbers of atoms and to reduce calculation time, the internal atomic coordinates were fixed. Considering one less O atom in PKU-15H than in PKU-15, the energy difference between PKU-15 and PKU-15H was calculated based on:

$$\Delta E = E_{\text{tot}}^{\text{PKU-15}} - E_{\text{tot}}^{\text{PKU-15H}} - \frac{1}{2} E_{\text{tot}}^{\text{O}_2},$$

where $E_{\text{tot}}^{\text{PKU-15}}$, $E_{\text{tot}}^{\text{PKU-15H}}$ and $E_{\text{tot}}^{\text{O}_2}$ are the total energies of PKU-15, PKU-15H and the O$_2$ molecule, respectively. The non-configurational entropy and electron entropy were not considered in this calculation.
