2-Pyridyl substituents enhance the activity of palladium—phospha-adamantane catalysts for the methoxycarbonylation of phenylacetylene†

Timothy A. Shuttleworth, Alexandra M. Miles-Hobbs, Paul G. Pringle* and Hazel A. Sparkes

The synthesis of a series of CgPAr ligands is reported, where CgP is the 6-phospha-2,4,8-trioxa-1,3,5,7-tetramethyladamant-6-yl moiety and Ar = 2-pyridyl (L_2), 3-pyridyl (L_3), 2-pyrimidyl (L_4), 4-R-2-pyridyl [R = Me (L_{5a}), CF $_3$ (L_{6a}), SiMe $_3$ (L_{7a})] or 6-R-2-pyridyl [R = Me (L_{5b}), CF $_3$ (L_{6b}), SiMe $_3$ (L_{7b}). Testing of these ligands in the Pd-catalysed methoxycarbonylation of phenylacetylene reveals that the activity and branched selectivity of the catalysts derived from these ligands varies as a function of the N-heterocycle, with the catalyst derived from L_{5b} being the most active of those tested. This, together with the poor performance of catalysts derived from L_3 supports the hypothesis that the catalysis proceeds by a "proton shuttling" mechanism, an idea that previously had only been applied to arylphosphines. Reaction of [PtCl₂(cod)] with L where L = L_2 or L_{4-7} yields a rac/meso mixture of the trans-[PtCl₂(L)₂] (1a-h) complexes, three of which are structurally characterised. ³¹P NMR spectroscopy shows that reaction of L_3 with [PtCl₂(cod)] gives a mixture of mononuclear and binuclear metal complexes in solution. The complex trans-[PdCl₂(L_2)₂] (1a) reacts with AgBF₄ to give the [PdCl(κ^1 - L_2)(κ^2 - L_2)]BF₄ (1a) with spectroscopic and structural characterisation confirming the presence of a P,N-chelate. ¹H and ³¹P NMR evidence supports the assignment of a pyridyl-protonated species being formed upon treatment of 1a with TsOH·H₂O in CD₂Cl₂; both the protonated species and chelate 1a0 are observed when the reaction is carried out in

Introduction

The palladium-catalysed methoxycarbonylation of alkynes (Scheme 1) is an atom-efficient way of producing branched or linear $\alpha.\beta$ -unsaturated esters from readily available feedstocks.^{1,2}

The methoxycarbonylation of propyne (Scheme 1, R = Me) has been extensively studied owing to the industrial interest in

Scheme 1

School of Chemistry, University of Bristol, Cantock's Close, Bristol, BS8 1TS, UK. E-mail: Paul.Pringle@bristol.ac.uk

the branched product, methyl methacrylate (MMA) which is a precursor to poly(methyl methacrylate).³ The methoxy-carbonylation of phenylacetylene (Scheme 1, R = Ph) produces methyl atropate (branched product), a precursor to ibuprofen² or methyl cinnamate (linear product), which has applications in the perfume and flavouring industries.⁴

The activity, selectivity and stability of the palladium catalyst for methoxycarbonylation depend critically on the ligand. Drent *et al.* reported that changing the ligand from PPh₃ to Ph₂P(2-py) (L₁) led to an increase in rate of three orders of magnitude for propyne and an increase in branched selectivity from 89% to 99%.³ It was postulated that a "non-classical" carbomethoxy mechanism involving P,N-chelates was in operation and the greater catalyst activity was a result of the Ph₂P(2-py) acting as a "proton messenger",³ by bringing the proton into close proximity to the metal and thereby promoting the protonolysis of the proposed vinyl-palladium intermediate as shown in Scheme 2.

Recently, Bühl *et al.* reported a computational study of several possible pathways for methoxycarbonylation.⁵ Drent's original mechanism was challenged, as it was found that the postulated, selectivity-determining transition state would

from $Ph_2P(2$ acetylene me It has also

Scheme 2 Drent's non-classical carbomethoxy mechanism.³

favour the formation of linear product (methyl crotonate) over the branched product (MMA). Instead, an alternative cycle involving labile P,N-chelates was proposed which proceeded by an *in situ* base mechanism (Scheme 3) 5 closely related to that described by Scrivanti *et al.* 6 This was suggested to be the most plausible mechanism due to it having surmountable barriers congruent with the high turnover and selectivity observed experimentally with L_1 . Common to the Drent and Bühl mechanisms (Schemes 2 and 3) is the chelation of the P,N ligand which acts to stabilise the catalyst. Catalysts derived

Scheme 3 Bühl's in situ base mechanism.⁵

from $Ph_2P(2-py)$ have been shown to be excellent for phenylacetylene methoxycarbonylation (Scheme 1, R = Ph).^{3,6}

It has also been observed that substituents on the 2-pyridyl ring have a pronounced effect upon the performance of the catalyst; moreover Ph₂P(3-py) and Ph₂P(4-py) give catalysts of much lower activity.³ Palladium complexes of other monophosphines with the potential to form heterodonor P,L-chelates (*e.g.* pyrimidylphosphines,⁷ iminophosphines,⁸ phosphinoquinilines,⁹ furylphosphines¹⁰ and so called TROPPs¹¹) have been shown to be efficient methoxycarbonylation catalysts. It is notable that in all of these ligands an Ar₂P moiety is present.¹²

Ligands incorporating the 6-phospha-2,4,8-trioxa-1,3,5,7-tetramethyladamant-6-yl (CgP) moiety are effective for a range of Pd-catalysed carbonylation reactions. CgPR and $^t\mathrm{Bu}_2\mathrm{PR}$ are comparable in terms of bulk but very different in σ/π -bonding characteristics: the donor properties of CgPR are comparable to a (PhO) $_2\mathrm{PR}$. It was therefore of interest to investigate CgP(2-py) (L2) and its derivatives as ligands for Pd-catalysed methoxycarbonylation of phenylacetylene. We show here that the Pd-L2 catalysts are active and that 4- and 6-substituents on the 2-pyridyl affect the performance of the catalyst. The platinum and palladium coordination chemistry of these ligands has been explored which has given some insight into the function of L2 and related ligands.

Results and discussion

Ligand synthesis

The synthesis of CgP(2-py) (L_2) has previously been reported via a Pd-catalysed P-arylation of $CgPH^{15}$ and we have extended the route to the preparation of cage phosphines containing 3-pyridyl (L_3), 2-pyrimidyl (L_4), 4-substituted-2-pyridyl (L_{5-7a}) and 6-substituted-2-pyridyl (L_{5-7b}) (Scheme 4). These air-stable ligands were purified by column chromatography and have been fully characterised. Crystals of all of the ligands L_{2-7} suitable for X-ray crystallography have been obtained. The structures are very similar to each other and so only L_2 , as a representative structure, is shown in Fig. 1 along with its main metrical parameters; the structures of L_{3-7} are given in the ESI.†

Methoxycarbonylation catalysis

In order to draw comparisons in performance among the ligands, the methoxycarbonylation of phenylacetylene (eqn (1)) has been carried out in the presence of L_{1-7} , PPh₃ and CgPPh under the same reaction conditions and the results are presented in Table 1.

Dalton Transactions Paper

Fig. 1 Crystal structure of L2. Hydrogen atoms omitted for clarity. Thermal ellipsoids at 50% probability. Selected bond lengths (Å) and bond angles (°): P1-C1 1.8857(12), P1-C4 1.8734(12), P1-C11 1.8395(12); C1-P1-C4 92.71(5), C1-P1-C11 101.83(5), C4-P1-C11 106.34(5).

Under the conditions we used for the catalysis, the PPh₃ catalyst produced low and inconsistent conversions (entry 1)

$$Ph = \begin{array}{c} Pd/L/H^{+} \\ \hline CO, MeOH \\ 60 \, ^{\circ}C \end{array} Ph \begin{array}{c} O \\ O \\ \hline \end{array} Me + Ph \begin{array}{c} O \\ O \\ \hline \end{array} Me \end{array} (1)$$

and at the end of the runs, copious amounts of black deposit, presumably metallic palladium, was observed indicating that the catalyst was not stable. As previously reported,⁴ the very high activity of the catalyst derived from L₁ (entry 3) contrasts sharply with that of the isosteric PPh3 analogue (entry 1). The CgPPh is superior to PPh3 in producing a moderately active catalyst (entry 2) that shows no evidence of decomposition to metallic Pd during the catalytic runs.

^a Reaction conditions: 5.5 mmol of phenylacetylene, 5.5×10^{-3} mmol of Pd(OAc)2, 2.2 mmol of p-tolylsulfonic acid monohydrate, 1.1 mmol of ligand, 1.5 cm³ of MeOH, 45 bar of CO, 60 °C. ^b Conversion and selectivity determined by ¹H NMR (see Experimental for details). Each result is an average of 2 or more runs. ^c The rest of the product was the linear isomer.

Ligand L₂ (entry 4) produced a higher activity catalyst than CgPPh (entry 3) indicating that the 2-pyridyl group has a positive effect within the CgPAr series of ligands. This is reinforced by the low activity observed with the 3-pyridyl isomer L₃ (entry 11). The pyrimidyl group in ligand L4 (entry 12) led to a catalyst with lower activity than L2.

The results for the catalysts derived from L_{5-7a} and L_{5-7b} show that substituents Me, CF3 and SiMe3 at the 4- and 6-positions in the 2-pyridyl ring can, in some cases, have a significant effect on the conversion compared to the unsubstituted L₂. However, there appears to be no consistent trends associated with the stereoelectronic effect of the substituents. Relative to L_2 : (1) the 4-Me ligand L_{5a} (entry 5) gives a significantly lower conversion while the 6-Me ligand L_{5b} (entry 6) gives a significantly higher conversion; (2) the 4-CF₃ and 4-SiMe₃ ligands, L_{6a} (entry 7) and L_{7a} (entry 9), perform similarly to L2 while the 6-CF3 and 6-SiMe3 ligands, L6b (entry 8) and L_{7b} (entry 10), produce catalysts of lower activity than L_2 . In terms of branched selectivity, there is some evidence that the 6-substituted 2-pyridyl ligands L_{5-7b} give more branchedselective catalysts than their 4-substituted isomers L5-7a (entries 5-10). Others have reported similar observations with 4- and 6-substituted pyridyl derivatives of L1; that is, greater branched selectivity was obtained with 6-substituted than with 4-substituted pyridyl ligands.4

In order to elucidate the function of the 2-pyridyl in the Pdcatalysis, the coordination chemistry of L2-7 with Pt and Pd has been investigated.

Coordination chemistry

Ligands L_{2-7} have been reacted with $[PtCl_2(cod)]$ (cod = 1,5cyclooctadiene) in CH2Cl2. With the exception of the reaction with L_3 (see below), products of the type trans- $[PtCl_2(L)_2]$ (1a-h) were obtained (Scheme 5) which have been fully characterised.

Scheme 5

The $^{31}\mathrm{P}$ NMR spectra of the products in each case showed two closely spaced singlets with $^{195}\mathrm{Pt}$ satellites ($^1J_{\mathrm{P-Pt}}$ values are typical of $trans\text{-}[\mathrm{PtCl_2}(\mathrm{PR_3})_2]$ complexes) consistent with the presence of rac and meso diastereomers resulting from the chirality of the cage ligands. 14

Crystals suitable for X-ray crystallography of **1c**, **1d**, **1e** and **1g** (*meso* isomers in each case) were grown by slow diffusion of hexane into a CH₂Cl₂ solution of a *rac/meso* mixture of the corresponding complex. As shown in Fig. 2–5, in each case, the ligands adopt an *anti* conformation, with the C(pyridyl)–P–P–C(pyridyl) torsion angle of 180°.

The reaction of [PtCl₂(cod)] with the 3-pyridyl ligand L_3 gave different results from those for all of the 2-pyridyl ligands L_2 , and L_{4-7} . The ³¹P NMR spectrum of the products of the reaction of [PtCl₂(cod)] with 2 equiv. of the 3-pyridyl ligand L_3 showed four signals with ¹⁹⁵Pt satellites, as well as free ligand $(\delta_P - 29.5 \text{ ppm})$. Two of the signals were assigned to rac/meso-[PtCl₂(L_3)₂] (1i) because of the similarity of their ³¹P NMR data $(\delta_P - 2.6 \text{ ppm}, {}^1J_{P,Pt} = 2703 \text{ Hz}; \delta_P - 2.8 \text{ ppm}, {}^1J_{P,Pt} = 2710 \text{ Hz})$ to those of the analogues 1a–h. The remaining two signals were assigned to binuclear complexes of the type [Pt₂Cl₂(L_3)₂(μ -Cl)₂]

Selected bond lengths (Å) and angles (°): Pt1-Cl1 2.3056(5), Pt1-P1 2.3227(5), P1-C1 1.877(2), P1-C4 1.886(3), P1-C11 1.842(2); C1-P1-C4 94.43(10), C1-P1-C11 105.04(13), C4-P1-C11 109.69(10).

on the basis of their large ${}^1J_{\rm P,Pt}$ values ($\delta_{\rm P}$ 8.3 ppm, ${}^1J_{\rm P,Pt}$ = 4592 Hz; $\delta_{\rm P}$ 7.9 ppm ${}^1J_{\rm P,Pt}$ = 4608 Hz). Two types of isomerism (syn/anti and rac/meso) would be expected for $[{\rm Pt_2Cl_2(L_3)_2(\mu\text{-Cl})_2}]$; in view of the 0.4 ppm difference in their $\delta_{\rm P}$ values, we tentatively assign the two observed ${}^{31}{\rm P}$ NMR signals to syn- and anti-2 (Scheme 6) with the signals expected for the rac and meso isomers unresolved. Mixtures of mononuclear and binuclear products were also reported in the reaction of $[{\rm PtCl_2(cod)}]$ with 2 equiv. CgPPh 14 and so the observation of exclusive formation of mononuclear complexes 1a-h appears to be an effect of the 2-pyridyl group. It is tempting to associate this with weak Pt···N interactions stabilising the mononuclear complexes

Dalton Transactions Paper

Fig. 5 Crystal structure of meso-1g, showing the anti-trans conformation adopted by the ligands. Disordered atoms in CgP moiety and hydrogen atoms omitted for clarity. Atoms suffixed with a dash (') are related by symmetry operation (1-x, -y, -z). Thermal ellipsoids at 50% probability. Selected bond lengths (Å) and angles (°): Pt1-Cl1 2.3022(5), Pt1-P1 2.3193(5), P1-C1 1.877(2), P1-C4 1.875(2), P1-C11 1.833(2); C1-P1-C4 94.23(9), C1-P1-C11 103.66(8), C4-P1-C11 111.82(9).

although in the solid state at least, no such interactions were detected in complexes 1c-e and 1g (see Fig. 2-5).

The ability of 2-pyridylphosphines to switch between P-monodentate and P,N-bidentate coordination has been invoked as part of the explanation for the high activity of Pdcomplexes of 2-pyridylphosphines in methoxycarbonylation.^{3,5,6} It was therefore of interest to investigate if 2-pyridylphosphine L₂ could form 4-membered P,N-chelates. Treatment of the trans complex 1a with 1 equiv. of AgBF4 gave a precipitate of AgCl and a solution whose ³¹P{¹H} NMR spectrum was consistent with the formation of the monochelate 3[BF₄] (Scheme 7). Two doublets were observed at -48.1 ppm (${}^{1}J_{P,Pt}$ = 2728 Hz) and +0.8 ppm (${}^{1}J_{P,Pt}$ = 3514 Hz) with a small ${}^{2}J_{P,P}$ of 11 Hz typical of cis coordinated phosphines. The signal at -48.1 ppm is assigned to the P,N-chelate since its high field shift is characteristic of a 4-membered chelate. 16 The lower

 \xrightarrow{P} \xrightarrow{P} \xrightarrow{N} BF₄ \xrightarrow{S} $\xrightarrow{$

Scheme 7

value of ${}^{1}J_{P,Pt}$ for the chelate-P is consistent with the ring strain being relieved by lengthened Pt-P bonds; the crystal structure of the Pd analogue 5[BF₄] (see below) supports this inference.

In a similar manner to that described above for the Pt analogues, reaction of [PdCl2(cod)] with 2 equiv. of L2 yielded trans-[PdCl₂(L₂)₂] (4) which has been fully characterised. Treatment of 4 with 1 equiv. of AgBF₄ gave a product assigned the structure 5[BF₄], the Pd analogue of 3[BF₄] (Scheme 8). Crystals of 5[BF₄] suitable for X-ray crystallography were obtained and its crystal structure determined (Fig. 6) which confirmed the cis orientation of the two P-donors. The chelate ring strain is apparent from the acute P-Pd-N angle of 69.0°. The Pd-P length within the chelate is longer (by ca. 0.02 Å)

Fig. 6 Crystal structure of 5[BF₄]. The [BF₄] counterion, hydrogen atoms and CH2Cl2 solvent molecule are omitted for clarity. Thermal ellipsoids at 50% probability. Selected bond lengths (Å) and angles (°): Pd1-Cl1 2.2989(10), Pd1-P1 2.3170(10), Pd1-P2 2.2779(10), Pd1-N1 2.073(3), P1-C11 1.829(4), P2-C26 1.819(4); P1-Pd1-P2 112.44(3), P1-Pd1-N1 68.95(9), P1-C11-N1 101.9(3), P2-Pd1-Cl1 86.17(4), P1-Pd1-Cl1 161.35(4), P2-Pd1-N1 176.87(9), C1-P1-C4 95.33(17), C16-P2-C19 94.48(16).

than that for the monodentate ligand perhaps reflecting the ring strain.

The ³¹P{¹H} NMR spectrum of 5[BF₄] in CHCl₂CHCl₂ showed a slightly broadened ($w_{1/2} \sim 8$ Hz) signal at 28.8 ppm, corresponding to the monodentate ligand, and a sharp doublet at -42.7 ppm (${}^{2}J_{P,P}$ = 3.2 Hz), assigned to the P,Nchelate. The signals remain distinct but broaden as the temperature is raised (e.g. $w_{1/2} \sim 70$ Hz at 100 °C in CHCl₂CHCl₂) indicating that cation 5 is fluxional, which is associated with intramolecular interchange of chelating and non-chelating P,N ligands. Iggo et al. have shown that the complex $[PdCl]\kappa^1-Ph_2P$ (2-py) $\kappa^2-Ph_2P(2-py)$ BF_4 (an analogue of $5[BF_4]$) is fluxional but with a coalescence temperature for the ³¹P NMR signals of -30 °C which is at least 150 °C lower than for cation 5. 17 The high barrier to exchange in 5 can be rationalised in terms of steric hindrance to Pd-P bond rotation which may be required in order for the pyridyl-nitrogen in the κ^1 -L₂ to coordinate. Energy barriers to M-P bond rotation in complexes containing cis-M(CgPH), moieties have previously been shown to be of the order of 50 kJ mol⁻¹.

Complex 4 is only sparingly soluble in CD_2Cl_2 but addition of 1.1 equiv. of $TsOH \cdot H_2O$ to a suspension of 4 in CD_2Cl_2 gave a homogenous yellow solution. The ³¹P NMR spectrum showed two broad peaks at 6.0 and 3.7 ppm ($w_{1/2} \sim 57$ Hz and 53 Hz respectively), which are tentatively assigned to diastereoisomers of protonated species such as 6 (Scheme 9) with rapid proton exchange rendering the ³¹P NMR signals equivalent on the NMR timescale. In the ¹H NMR spectrum of 6 a broad signal centred at 6.55 ppm is assigned to the exchanging N–H. When a suspension of 4 in MeOH was treated with TsOH, the ³¹P NMR spectrum of the resulting solution displayed two broad signals at 6.3 and 4.5 ppm (assigned to 6) but in addition, two signals at 28.8 and -42.2 ppm are present, suggesting that the P,N-chelate 5[OTs] is also generated (Scheme 9).

The Pd and Pt coordination chemistry of L_2 has shown that the ligand can be monodentate (κ^1) or chelating (κ^2) and the pyridyl-N can be protonated by TsOH. These properties are essential for the catalyst to be able to function in a manner

Scheme 9

similar to L_1 shown in Schemes 1 and 2. Tellingly, the $^{31}P\{^1H\}$ NMR spectrum of the mixture obtained after catalysis runs involving Pd and L_2 showed, amongst other peaks, a prominent signal at -37.8 ppm, reminiscent of the peak observed at -42.1 ppm for the cation 5, suggesting that a four-membered Pd chelate is present.

Conclusions

A series of substituted pyridyl-functionalised phospha-adamantyl ligands L_{2-7} have been made and fully characterised. It was found that, in some cases, substituents on the pyridyl ring had a marked effect on the rate of Pd-catalysed methoxycarbonylation of phenylacetylene. The 6-methyl substituted ligand L_{5b} showed good activity and selectivity for the branched product albeit lower than that of the well-known $Ph_2P(2-py)$ (L_1). The catalytic performance is a function of the substituents on the pyridine consistent with the idea that a mechanism involving P,N-chelation and "proton shuttling" may be operating.

The Pt and Pd coordination chemistry of L_{2-7} has been probed and the ability of the ligands to form P,N-chelates has been established in solution from the characteristic ³¹P NMR spectra and in the solid state by the crystal structure of a palladium complex containing L_2 ligands bound in a κ^1 - and κ^2 -mode. Moreover protonation of the pyridyl-N in a Pd- L_2 complex has been observed in solution. In contrast to the CgP(2-py) ligands, the CgP(3-py) ligand L_3 gives binuclear Pt complexes in a similar fashion to the CgPPh.

The methoxycarbonylation activity with catalysts derived from CgP(2-py) and its derivatives demonstrates that the 2-pyridyl effect is not restricted to $Ph_2P(2-py)$ and its derivatives. The CgP and Ph_2P moieties has very different stereoelectronic effects and therefore the results presented hold out the prospect that other $R_2P(2-py)$ ligands may be useful for alkyne methoxycarbonylation catalysis.

Experimental

General procedures

All reactions were carried out under an atmosphere of dry nitrogen, unless otherwise stated, using standard Schlenk line techniques and oven dried (200 °C) glassware. CH_2Cl_2 and hexane were collected from a Grubbs type solvent purification system, and deoxygenated by bubbling with N_2 for 30 minutes. Xylene and CD_2Cl_2 were dried over activated 4 Å molecular sieves for 72 hours and deoxygenated by successive freeze–pump–thaw cycles. MeOH was purchased as anhydrous, stored over 3 Å molecular sieves and deoxygenated by bubbling with N_2 for 30 minutes. Other commercial reagents were used as supplied unless otherwise stated. [PtCl₂(cod)], ¹⁹ [PdCl₂(cod)], ²⁰ [1,3,5,7-tetramethyl-4,6,8-trioxa-2-phospha-adamantane (CgPH), ²¹ CgPPh, ¹⁴ Ph₂P(2-py)²² (L₁) 2-bromo-4-(trimethylsilyl)pyridine, ²³ and 2-bromo-6-(trimethylsilyl)pyridine were synthesised accord-

Dalton Transactions

ing to literature procedures. ¹H, ¹¹B, ¹³C, ¹⁹F and ³¹P NMR spectra were recorded at ambient temperature unless otherwise stated, on Jeol ECP (Eclipse) 300, Jeol ECS 300, Jeol ECS 400, Varian 400-MR, Varian VNMRS 500 spectrometers and a Bruker Avance III HD 500 spectrometer equipped with a ¹³C-observe (DCH) cryogenic probe. Chemical shifts δ are given in parts per million (ppm) and coupling constants J are in Hz. ¹H and ¹³C chemical shifts were referenced to residual solvent peaks. ¹¹B, ¹⁹F and ³¹P chemical shifts were referenced to BF₃·OEt₂, CFCl₃ and 85% H₃PO₄ respectively. Mass Spectra were recorded by the University of Bristol Mass Spectrometry Service on VG Analytical Autospec (EI) or VG Analytical Quattro (ESI) spectrometers. Elemental Analysis was carried out by the Microanalytical Laboratory of the School of Chemistry, University of Bristol. X-ray crystallography was performed by the University of Bristol X-ray Analytical Service using Bruker AXS Microstar or Bruker Kappa Apex II diffractometers. Thin Layer Chromatography (TLC) was performed using Merck Kieselgel 60 F₂₅₄ (Merck) aluminium backed plates (0.25 mm layer of silica). Flash column chromatography was performed using a Biotage Isolera Spektra One Chromatographic Isolation system.

General procedure for the synthesis of pyridyl-functionalised phospha-adamantyl ligands. A Schlenk flask was charged with a suspension of CgPH (1 equiv.), K_2CO_3 (3 equiv.) and $[Pd(PPh_3)_4]$ (3 mol%) in xylene (6 cm³). The desired ArBr (1.2 equiv.) was added and the mixture heated to 110 °C and stirred for 24 h. The mixture was then allowed to cool and, in air, passed through silica, eluting with Et_2O . Removal of the solvents *in vacuo* yielded the crude product.

CgP(2-py) (L₂). Prepared according to a literature procedure.¹⁴ Crystals suitable for X-ray diffraction were grown by slow diffusion of hexane into a CH_2Cl_2 solution of the product. Spectroscopic data the same as those reported.

CgP(3-py) (L₃). Purification by flash column chromatography (20% EtOAc/hexane) yielded the product as a white solid (0.432 g, 71%). Crystals suitable for X-ray diffraction were grown by slow diffusion of hexane into a CH2Cl2 solution of the product. ¹H NMR (400 MHz, CDCl₃): $\delta_{\rm H}$ 8.93–8.92 (m, 1H, ArH (H-2)), 8.61-8.59 (m, 1H, ArH (H-6)), 8.19-8.15 (m, 1H, ArH (H-4)), 7.31–7.26 (m, 1H, ArH (H-5)), 2.05 (dd, ${}^{2}J_{H,H}$ = 13.3 Hz, ${}^{3}J_{H,P}$ = 7.3 Hz, 1H, CgP C H_2), 1.94 (dd, ${}^{3}J_{H,P}$ = 25.1 Hz, $^{2}J_{H,H}$ = 13.3 Hz, 1H, CgP C H_{2}), 1.66 (d, $^{2}J_{H,H}$ = 13.5 Hz, 1H, CgP CH_2), 1.51 (dd, ${}^2J_{H,H}$ = 13.4 Hz, ${}^3J_{H,P}$ = 4.3 Hz, 1H, CgP CH_2), 1.49 (d, ${}^{3}J_{H,P}$ = 12.8 Hz, 3H, CgP CH₃), 1.41 (s, 6H, CgP CH₃), 1.25 (d, ${}^{3}J_{H,P}$ = 13.3 Hz, 3H, CgP C H_3). ${}^{13}C\{{}^{1}H\}$ NMR (101 MHz, CDCl₃): $\delta_{\rm C}$ 155.6 (d, ${}^2J_{\rm C,P}$ = 26.4 Hz, ArC (C-2)), 150.5 (s, ArC (C-6)), 142.3 (d, ${}^{2}J_{C,P} = 14.5$ Hz, ArC (C-4)), 130.6 (d, ${}^{1}J_{C,P} =$ 32.4 Hz, ArC (C-3)), 123.6 (d, ${}^{3}J_{C,P}$ = 4.4 Hz, ArC (C-5)), 97.0 (s, CgP quat. Paper

TsOH·H₂O (0.003 g, 0.015 mmol) was added to a suspension of 4 (0.010 g, 0.013 mmol) in CD₂Cl₂ (0.7 cm³), upon which the solution became homogeneous, yielding species assigned to the protonated species **6**. 31 P{ 1 H} NMR (121 MHz, CD₂Cl₂): δ_{P} 6.0 (br s, Cg*P*) and 3.7 (br s, Cg*P*). An analogous procedure in MeOH (0.7 cm³) also gave a homogenous solution, assigned to be a mixture of **6** and a P,N-chelate species related to 5[OTs]. 31 P{ 1 H} NMR (121 MHz, CD₂Cl₂): δ_{P} 28.8 (br s, monodentate Cg*P*), 6.3 (br s, Cg*P*) and 4.5 (br s, Cg*P*), -42.2 (br s, chelate Cg*P*).

Phenylacetylene methoxycarbonylation

Adapted from previously reported procedure.9 Catalysis was performed using a Baskerville Multi-Cell autoclave. The ligand (0.11 mmol) was added to the autoclave and the system put under an atmosphere of N₂. Solutions of Pd(OAc)₂ (0.0055 mmol) in MeOH (0.5 $\rm cm^3$) and TsOH·H₂O (0.22 mmol) in MeOH (0.5 cm³) were then added, followed by phenylacetylene (5.5 mmol). This was then washed in using MeOH (0.5 cm³) and the autoclave flushed with three cycles of CO (ca. 10 bar). The autoclave was then pressurised to 45 bar and heated to 60 °C. After 1 hour or 4.5 hours, the autoclave was transferred to an ice bath and once cooled, the system was vented. A small amount of each sample was dissolved in CDCl₃ and analysed by ¹H NMR spectroscopy. Conversion and selectivity was determined by integration of the phenylacetylene alkynyl proton ($\delta_{\rm H}$ 3.10 ppm) and the methyl atropate ($\delta_{\rm H}$ 6.38 and 5.90 ppm) and methyl cinnamate ($\delta_{\rm H}$ 7.71 and 6.42 ppm) alkenyl protons.

X-ray crystallography

All of the X-ray diffraction data were collected at 100 K on a Bruker Apex II diffractometer with CCD area detector using Mo-K α radiation (λ = 0.71073 Å). Absorption corrections were carried out using SADABS.²⁵ All of the structures were solved using Superflip^{26,27} and refined by full matrix least squares on F^2 using ShelXL^{28,29} within Olex2.³⁰ The structure of *meso-1g* displayed disorder in the cage, the occupancies of the disordered atoms were refined with the sum of the occupancies

set to 1 before being fixed at the refined values. Restraints were applied to the bond lengths and the thermal parameters of pairs of disordered atoms on almost the same site were constrained to be equal. The structure of 5 was twinned and refined as a 2-component twin. In addition, the BF₄⁻ counterion displayed disorder in the fluorine positions, the sum of the occupancies were set to equal 1 and refined before being fixed at the refined values. Restraints were applied to maintain sensible thermal parameters and B–F distances. Crystal structure and refinement details are given in Tables S1–S3 in ESI.† Crystallographic data for the compounds have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication, CCDC 1497885–1497898.

Acknowledgements

The Bristol Chemical Synthesis Centre for Doctoral Training (BCS CDT) funded by the Engineering and Physical Sciences Research Council (EPSRC) (EP/G036764/1) and the University of Bristol are thanked for a PhD studentship (to T. A. S.).
