Determination of ZFS parameters from the EPR spectra of mono-, di- and trinuclear Mn^{II} complexes: impact of magnetic coupling†

Luis Escriche-Tur,^{*a,b} Mercè Font-Bardia,^c Belén Albela^b and Montserrat Corbella^{*a,d}

A family of new Mn^{II} compounds, consisting of seven dinuclear, three mononuclear, and four trinuclear ones, were synthesised using benzoic acid derivatives *n*-RC₆H₄COOH, where *n*-R = 2-MeO, 3-MeO, 4-MeO, or 4-^tBu, and 2,2'-bipyridine (bpy) or 1,10-phenanthroline (phen) as blocking ligands. The crystal structures of nine of these compounds and the magnetic studies of all of them are reported here. Each type of compound was formed depending on the presence or absence of ClO₄[−] ions, the solvent used, and/or the presence of a small amount of water in the reaction medium. The use of the *tert*-butylbenzoate ligand gave unexpected results, very likely due to the steric hindrance caused by the voluminous ^tBu groups. The EPR spectra of each type of compound give some peculiar features that allow its identification. Attempts to fit these spectra have been made in order to determine the ZFS parameters, *D* and *E*, of the Mn^{II} ion (for mononuclear and dinuclear systems) or of the ground state (for trinuclear systems). For trinuclear systems, the single-ion ZFS parameters estimated from those of the ground state provided a good simulation of the EPR spectra of these compounds. The EPR signals observed in each case have been rationalised according to the energy level distribution and the plausible population in the excited states. In some particular situations, the sign of *D*_{Mn} could be determined from the fit of the EPR spectra of the antiferromagnetic dinuclear compounds, the source of the difference between the spectra lying in the second excited state.

Introduction

Mn^{II} complexes are widely present in numerous enzymes, as an essential ingredient of their active site.¹ Mn^{II} ions can be implicated in both redox and non-redox processes, acting as

catalysts or having a structural role.^{2–5} Owing to its single-ion high spin (*S* = 5/2) and comparable size, Mn^{II} is commonly used as a probe to replace diamagnetic ions, such as Mg²⁺,^{6,7} in other biological systems. Additionally, some Mn^{II} compounds can be used as catalysts in several industrial processes, commonly for the epoxidation of olefins,^{8–12} making them good candidates to replace 2nd and 3rd row transition metal ions in oxidation catalysis.

From the analyses of EPR spectra of Mn^{II} compounds, important information can be extracted, since the splitting of the magnetic sublevels will depend on the zero-field splitting (ZFS) parameters, *D* and *E*. Indeed, even a slight distortion from a regular octahedral environment can result in significant ZFS parameters and highly complicated EPR spectra.¹³ Furthermore, it is well known that, for several transition metal ions, the ZFS can probe their structural and electrostatic environments.¹⁴ For example, the ZFS for Mn^{II} ions is larger when it is bonded to halide ligands.^{13,15–22} It also depends on the coordination number, since pentacoordinated ions display greater axial ZFS parameters ($|D| = 0.25\text{--}0.30\text{ cm}^{-1}$) than hexacoordinated ones ($|D| = 0.0008\text{--}0.1750\text{ cm}^{-1}$).^{23,24} Moreover, the ZFS parameters could also be affected by the ratio between the N- and O-based ligands.²⁵

The reaction between Mn^{II} carboxylate and bidentate ligands (NN), such as 2,2'-bipyridine (bpy) and 1,10-phenanthroline (phen), leads to the formation of Mn^{II} compounds with different nuclearity: mononuclear, dinuclear, trinuclear, or 1D systems.^{26,27} The carboxylate groups display a wide variety of coordination modes, such as monodentate terminal, chelating, bidentate bridging, and monodentate bridging modes. Particularly in these compounds, the carboxylate ligands could bridge the Mn^{II} ions in $\mu_{1,1}$ or $\mu_{1,3}$ coordination modes, and in the latter case in either a *syn-syn* or *syn-anti* conformation.

The magnetic interaction between neighboring Mn^{II} ions depends on the coordination mode of the carboxylate ligand. For instance, dinuclear compounds with $\mu_{1,1}$ -carboxylate bridges present a ferromagnetic interaction ($S = 5$ ground state), while those with $\mu_{1,3}$ -carboxylate bridges show an anti-ferromagnetic interaction ($S = 0$ ground state).²⁶

We herein present three kinds of compounds: dinuclear $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2](\text{ClO}_4)_2$ (1–7), mononuclear $[\text{Mn}(\text{NN})_{3-m}(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_m(\text{H}_2\text{O})_x](\text{ClO}_4)_{2-m}$ (with $m = 1$ or 2 and $x = 0, 1$, or 2) (8–10), and trinuclear $[\text{Mn}_3(\text{NN})_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_6]$ (11–14) compounds, synthesised with $n\text{-MeOC}_6\text{H}_4\text{COO}^-$ ($n = 2, 3, 4$) or $4\text{-}^t\text{BuC}_6\text{H}_4\text{COO}^-$ ligands, and NN = bpy or phen. The magnetic properties of these compounds have been studied and their EPR spectra have been deeply analysed. Moreover a qualitative rationalisation of the displayed EPR signals has been performed. Fits of these spectra have been attempted, leading to a reasonable determination of the zero field splitting parameters, D and E . The Zeeman plots of the dinuclear compounds have been deeply analysed to provide a better understanding of the EPR spectra.

Experimental section

Synthesis

All manipulations were performed under aerobic conditions. Reagents and solvents were obtained from commercial sources and used without further purification. **Caution!** Perchlorate salts of compounds containing organic ligands are potentially explosive. Only small quantities of these compounds should be prepared. $\text{Mn}(n\text{-MeOC}_6\text{H}_4\text{COO})_2 \cdot x\text{H}_2\text{O}$ ($n = 2$ and 4) was obtained from the reaction between MnCO_3 and $n\text{-MeOC}_6\text{H}_4\text{COOH}$ in boiling water. After several hours, the solution was filtered and concentrated to give a pale pink precipitate of the desired product. For $n = 2$, $\text{C}_{16}\text{H}_{14}\text{MnO}_6$ (M.W. = $357.16 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 53.80; H, 3.95. Found (%): C, 52.20; H, 3.90. For $n = 4$, $\text{C}_{16}\text{H}_{14}\text{MnO}_6 \cdot 2\text{H}_2\text{O}$ (M.W. = $393.25 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 48.87; H, 4.61. Found (%): C, 49.2; H, 4.70. $\text{Mn}(3\text{-MeOC}_6\text{H}_4\text{COO})_2 \cdot 2/3\text{EtOH}$ was obtained following the same procedure but assisting the crystallisation by adding EtOH to the mother liquor and leaving it undisturbed in the refrigerator. $\text{C}_{16}\text{H}_{14}\text{MnO}_6 \cdot 2/3\text{EtOH}$ (M.W. = $387.93 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 53.67; H, 4.67. Found (%): C, 53.37; H, 4.80. $\text{Mn}(4\text{-}^t\text{BuC}_6\text{H}_4\text{COO})_2 \cdot 3\text{H}_2\text{O}$ was obtained following the same procedure as for $n\text{-R} = 2\text{-MeO}$ and 4-MeO

but using $\text{Mn}(\text{AcO})_2$ instead of MnCO_3 . $\text{C}_{22}\text{H}_{26}\text{MnO}_4$ (M.W. = $463.42 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 57.02; H, 6.96. Found (%): C, 57.70; H, 6.80.

[{Mn(bpy)}₂](μ-2-MeOC₆H₄COO)₂](ClO₄)₂ (1). $\text{Mn}(2\text{-MeOC}_6\text{H}_4\text{COO})_2$ (0.30 mmol, 0.11 g) was dissolved in an EtOH:H₂O 1:1 (v/v) mixture (30 mL) by stirring for around 24 h. Then, a solution of NaClO₄ (0.33 mmol, 0.041 g) in EtOH:H₂O 1:1 (v/v) (10 mL) was added to the previous one. Meanwhile, 2,2'-bipyridine (bpy) (0.72 mmol, 0.11 g) was dissolved in EtOH (10 mL) and added to the previous solution. The resulting yellow solution (solvent: 50 mL of EtOH:H₂O 3:2) was stirred for 15 minutes and filtered to separate any possible impurity. Then, the solution was left undisturbed at room temperature. The crystallisation of the product begins after a month of slow evaporation and may last up to six months. During this time, neither oxidation nor decomposition of the sample was observed. Yield: 65%. X-ray suitable single-crystals were obtained from the mother liquor. $\text{C}_{56}\text{H}_{46}\text{Cl}_2\text{Mn}_2\text{N}_8\text{O}_{14}$ (M.W. = $1235.79 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 54.43; H, 3.75; N, 9.07. Found (%): C, 54.49; H, 3.90; N, 9.19. IR (cm⁻¹): 3435 (br), 3114 (w), 3078 (w), 3007 (w), 2981 (w), 2950 (w), 2841 (w), 1592 (s), 1567 (s), 1489 (m), 1472 (m), 1438 (s), 1403 (s), 1313 (m), 1280 (m), 1245 (m), 1193 (w), 1171 (m), 1092 (br,s), 1015 (s), 847 (m), 774 (m), 750 (m), 737 (m), 647 (w), 622 (m), 572 (w), 520 (w), 410 (m).

[{Mn(bpy)}₂](μ-3-MeOC₆H₄COO)₂](ClO₄)₂ (2). $\text{Mn}(3\text{-MeOC}_6\text{H}_4\text{COO})_2 \cdot 2/3\text{EtOH}$ (0.23 mmol, 0.09 g) and $\text{Mn}(\text{ClO}_4)_2$ (0.25 mmol, 0.09 g) were dissolved in a mixture of CH₃CN (15 mL) and H₂O (5 mL). Then, bpy (1.0 mmol, 0.16 g) was dissolved in CH₃CN (10 mL) and added to the previous solution, giving a yellow solution (total volume ~40 mL). After 7 months of slow evaporation, yellow crystals were filtered and washed with cold CH₃CN. Yield: 76%. X-ray suitable single-crystals were isolated from the mother liquor. $\text{C}_{56}\text{H}_{46}\text{Cl}_2\text{Mn}_2\text{N}_8\text{O}_{14}$ (M.W. = $1235.79 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 54.43; H, 3.75; N, 9.07. Found (%): C, 54.19; H, 3.83; N, 9.18. IR (cm⁻¹): 3446 (br), 3112 (w), 3087 (w), 2935 (w), 2834 (w), 1602 (s), 1575 (s), 1492 (w), 1474 (m), 1452 (m), 1438 (s), 1397 (s), 1312 (m), 1279 (m), 1244 (m), 1161 (w), 1086 (br,s), 1046 (m), 1015 (w), 814 (w), 768 (s), 738 (m), 683 (w), 666 (w), 648 (w), 622 (m), 558 (w), 422 (m).

[{Mn(bpy)}₂](μ-4-MeOC₆H₄COO)₂](ClO₄)₂ (3). $\text{Mn}(4\text{-MeOC}_6\text{H}_4\text{COO})_2 \cdot 2\text{H}_2\text{O}$ (0.50 mmol, 0.20 g) was dissolved in CH₃CN:H₂O 1:1 (v/v) (20 mL), to which a solution of NaClO₄ (0.50 mmol, 0.073 g) in CH₃CN:H₂O 1:1 (10 mL) was added. Then, another solution of bpy (1.20 mmol, 0.19 g) in CH₃CN:H₂O 1:1 (10 mL) was also added. The resulting yellow solution was left undisturbed at room temperature to obtain yellow needles after 3 weeks of slow evaporation. Yield: 82%. Single-crystals suitable for X-ray characterisation were obtained after two months of keeping the solution in the fridge. $\text{C}_{56}\text{H}_{46}\text{Cl}_2\text{Mn}_2\text{N}_8\text{O}_{14}$ (M.W. = $1235.79 \text{ g mol}^{-1}$). Anal. Calcd (%): C, 54.43; H, 3.75; N, 9.07. Found (%): C, 54.31; H, 3.81; N, 9.18.

[{Mn(phen)}₂](μ-2-MeOC₆H₄COO)₂](ClO₄)₂ (4). $\text{Mn}(2\text{-MeOC}_6\text{H}_4\text{COO})_2$ (0.12 mmol, 0.042 g) was dissolved in an

EtOH:H₂O 3:2 (v/v) mixture (25 mL) by stirring for around 24 h. Then, a solution of NaClO₄ (0.12 mmol, 0.014 g) in EtOH:H₂O (v/v) (10 mL) was added to the previous one. Meanwhile, 2,2'-bipyridine (bpy) (0.23 mmol, 0.046 g) was dissolved in EtOH (10 mL) and added to the other solution. The resulting yellow solution (solvent: 45 mL of EtOH:H₂O 4:5) was stirred for 15 minutes and filtered to separate any possible impurity. After 2 weeks of slow evaporation at room temperature, big yellow crystals were collected by filtration and washed with EtOH. Yield: 80%. C₆₄H₄₆Cl₂Mn₂N₈O₁₄ (M.W. = 1331.88 g mol⁻¹). Anal. Calcd (%): C, 57.71; H, 3.48; N, 8.41. Found (%): C, 56.47; H, 3.37; N, 8.20. IR (cm⁻¹): 3442 (br), 3065 (w), 2964 (w), 2832 (w), 1610 (s), 1588 (s), 1564 (s), 1513 (m), 1492 (w), 1458 (w), 1223 (m), 1390 (m), 1340 (w), 1300 (w), 1274 (w), 1241 (w), 1153 (m), 1100 (vs), 1015 (m), 847 (s), 778 (w), 759 (w), 730 (m), 660 (w), 642 (w), 615 (m), 567 (w), 419 (w).

[{Mn(phen)₂}(μ-4'-BuC₆H₄COO)₂](ClO₄)₂ (5). Mn(4'-BuC₆H₄COO)₂·3H₂O (0.12 mmol, 0.054 g) and NaClO₄ (0.12 mmol, 0.014 g) were dissolved in absolute EtOH (10 mL). Phen (0.23 mmol, 0.046 g) dissolved in absolute EtOH was added to the previous solution and the mixture was stirred for 10 minutes. Then, H₂O (4 mL) was added and the solution was left undisturbed at room temperature. After two weeks of slow evaporation, yellow crystals were filtered and washed with EtOH. Yield: 18%. X-ray suitable crystals were obtained from the mother liquor. IR (cm⁻¹): 3430 (br), 3071 (w), 2950 (w), 1609 (s), 1558 (m), 1515 (m), 1394 (s), 1339 (w), 1298 (w), 1267 (w), 1194 (w), 1152 (m), 1099 (vs), 1012 (w), 850 (s), 792 (m), 775 (m), 731 (s), 623 (s), 543 (w), 420 (w).

[{Mn(phen)₂}(μ-3-MeOC₆H₄COO)₂](ClO₄)₂ (6). Mn(3-MeOC₆H₄COO)₂·2/3EtOH (0.31 mmol, 0.12 g) and NaClO₄ (0.30 mmol, 0.040 g) were dissolved in MeOH. Then, 1,10-phenantroline (phen) (0.60 mmol, 0.12 g) was dissolved in MeOH and added to the previous mixture, giving a yellow solution (total volume ~50 mL). After stirring for 15 minutes, the solution was filtered to separate any possible impurities. After two weeks of slow evaporation at room temperature, yellow crystals were filtered and washed with MeOH. Yield: 80%. C₆₄H₄₆Cl₂Mn₂N₈O₁₄ (M.W. = 1331.88 g mol⁻¹). Anal. Calcd (%): C, 57.71; H, 3.48; N, 8.41. Found (%): C, 55.89; H, 3.55; N, 8.40. IR (cm⁻¹): 3435 (br), 3062 (w), 2999 (w), 2940 (w), 2840 (w), 1618 (s), 1577 (m), 1520 (m), 1456 (w), 1428 (s), 1306 (s), 1283 (m), 1231 (w), 1150 (m), 1186 (vs), 1043 (m), 852 (s), 775 (m), 731 (s), 622 (s), 423 (w).

[{Mn(phen)₂}(μ-4-MeOC₆H₄COO)₂](ClO₄)₂ (7). Mn(4-MeOC₆H₄COO)₂·2H₂O (0.30 mmol, 0.14 g) and NaClO₄ (0.12 mmol, 0.014 g) were dissolved in a CH₃CN:H₂O 2:1 mixture (15 mL). Then, a solution of phen (0.60 mmol, 0.12 g) in CH₃CN (5 mL) was added to the previous solution and the mixture was stirred for 15 minutes. Afterwards, MeOH (30 mL) was added. After a month of slow evaporation yellow single-crystals were filtered and washed with MeOH. Yield: 95%. C₆₄H₄₆Cl₂Mn₂N₈O₁₄ (M.W. = 1331.88 g mol⁻¹). Anal. Calcd (%): C, 57.71; H, 3.48; N, 8.41. Found (%): C, 57.34; H, 3.59; N, 8.48. IR (cm⁻¹): 3435 (br), 3062 (w), 2999 (w), 2941 (w), 2840 (w), 1618 (s), 1578 (s), 1521 (s), 1456 (w), 1482 (s),

[Mn(H₂O)(3-MeOC₆H₄COO)(phen)₂](ClO₄)₂ (8). Mn(3-MeOC₆H₄COO)₂·2/3EtOH (0.12 mmol, 0.045 g) and NaClO₄ (0.12 mmol, 0.014 g) were dissolved in CH₃CN (10 mL). H₂O (2 mL) was added to assist the complete dissolution of all reagents. Then, phen (0.12 mmol, 0.046 g) dissolved in CH₃CN (10 mL) was added to the previous solution. After 20 days of slow evaporation yellow crystals were filtered and washed with CH₃CN. Yield: 80%. X-ray suitable crystals were obtained from the mother liquor. C₃₂H₂₅ClMnN₄O₈ (M.W. = 683.95 g mol⁻¹). Anal. Calcd (%): C, 56.19; H, 3.68; N, 8.19. Found (%): C, 55.85; H, 3.77; N, 8.23. IR (cm⁻¹): 3442 (m), 3063 (w), 3008 (w), 2935 (w), 2837 (w), 1558 (m), 1517 (s), 1425 (s), 1379 (s), 1341 (w), 1315 (w), 1280 (w), 1249 (m), 1098 (s), 1035 (m), 854 (s), 772 (s), 724 (s), 623 (m), 421 (m).

[Mn(H₂O)₂(2-MeOC₆H₄COO)₂(phen)] (9). Phen (0.12 mmol, 0.023 g) dissolved in EtOH (10 mL) was added to a solution of Mn(2-MeOC₆H₄COO)₂ (0.12 mmol, 0.042 g) in EtOH:H₂O 4:3 (35 mL). The resulting pale yellow solution was stirred for 15 minutes. After 1 month of slow evaporation, yellow crystals were filtered and washed with EtOH. Yield: 65%. X-ray suitable single-crystals were obtained from the mother liquor. C₂₈H₂₆MnN₂O₈ (M.W. = 573.45 g mol⁻¹). Anal. Calcd (%): C, 58.64; H, 4.57; N, 4.89. Found (%): C, 58.56; H, 4.69; N, 5.03. IR (cm⁻¹): 3448 (s), 2967 (w), 2939 (w), 2837 (w), 1603 (s), 1544 (s), 1513 (m), 1423 (m), 1376 (s), 1292 (w), 1270 (m), 1236 (m), 1186 (w), 1163 (w), 1099 (m), 1057 (w), 1019 (m), 859 (m), 832 (m), 767 (s), 733 (m), 660 (w), 637 (w), 554 (w), 443 (w).

[Mn(bpy)(4'-BuC₆H₄COO)₂·H₂O (10). A solution of bpy (2 mmol, 0.33 g) in CH₃CN was added to an acetonitrile solution containing Mn(4'-BuC₆H₄COO)₂·3H₂O. Almost immediately a pale yellow suspension was formed. After 5 minutes of stirring, the solid was filtered and washed with CH₃CN. Yield: 70%. Tiny single-crystals were obtained from the mother liquor several months after the separation of the previous solid. C₃₂H₃₆MnN₂O₅ (M.W. = 583.57 g mol⁻¹). Anal. Calcd (%): C, 65.86; H, 6.22; N, 4.08. Found (%): C, 63.63; H, 6.39; N, 4.03. IR (cm⁻¹): 3425 (br), 3067 (w), 2963 (m), 2903 (w), 2868 (w), 1602 (s), 1553 (s), 1491 (w), 1475 (m), 1441 (m), 1401 (s), 1316 (w), 1267 (w), 1190 (w), 1148 (w), 1106 (w), 1058 (w), 1017 (m), 861 (m), 788 (m), 769 (m), 714 (m), 649 (w), 585 (w), 543 (w), 559 (w), 414 (w).

[Mn₃(bpy)₂(μ-3-MeOC₆H₄COO)₆] (11). Mn(3-MeOC₆H₄COO)₂·2/3EtOH (0.12 mmol, 0.045 g) was dissolved in CH₃CN (10 mL) and H₂O (5 mL). Then, bpy (0.078 mmol, 0.012 g) dissolved in CH₃CN (10 mL) was added to the previous solution. After 1 month of slow evaporation, yellow crystals were filtered and washed with CH₃CN. Yield: 43%. C₆₈H₅₈Mn₃N₄O₁₈ (M.W. = 1384.02 g mol⁻¹). Anal. Calcd (%): C, 59.01; H, 4.22; N, 4.05. Found (%): C, 58.72; H, 4.22; N, 4.15. IR (cm⁻¹): 3444 (br), 3108 (w), 3001 (w), 2963 (w), 2938 (w), 2831 (w), 1598 (m), 1565 (s), 1473 (w), 1452 (m), 1400 (s), 1315 (m), 1282 (m), 1239 (s), 1177 (w), 1157 (m), 1108 (w), 1047 (s), 1018 (m), 902 (m), 785 (m), 764 (s), 684 (w), 670 (w), 647 (w), 625 (w), 543 (w), 450 (w).

[Mn₃(bpy)₂(μ-4-MeOC₆H₄COO)₆] (12). Bpy (0.50 mmol, 0.08 g) dissolved in EtOH was added to a suspension of Mn(4-MeOC₆H₄COO)₂·2H₂O (0.75 mmol, 0.29 g) in EtOH. The resulting pale yellow mixture was stirred for 10 minutes. Then, the solid was separated by filtration and washed with Et₂O. Yield: 76%. X-ray suitable single-crystals were obtained by slow diffusion of a solution of bpy (0.008 g) in CH₃CN (8 mL) to another one containing Mn(4-MeOC₆H₄COO)₂·2H₂O (0.03 g) in CH₃CN (8 mL) after 6 months. C₆₈H₅₈Mn₃N₄O₁₈ (M.W. = 1384.02 g mol⁻¹). Anal. Calcd (%): C, 59.01; H, 4.22; N, 4.05. Found (%): C, 56.65; H, 4.05; N, 4.05. IR (cm⁻¹): 3433 (br), 3081 (w), 2953 (w), 2835 (w), 1606 (s), 1557 (s), 1488 (w), 1471 (m), 1440 (m), 1390 (s), 1310 (m), 1256 (s), 1168 (s), 1140 (m), 1103 (w), 1029 (w), 851 (m), 785 (s), 763 (m), 737 (w), 699 (m), 615 (m), 569 (w), 509 (w), 414 (m).

[Mn₃(μ-3-MeOC₆H₄COO)₆(phen)₂] (13). Mn(3-MeOC₆H₄COO)₂·2/3EtOH (0.12 mmol, 0.045 g) was dissolved in EtOH (15 mL) and H₂O (5 mL). Then, phen (0.078 mmol, 0.015 g) dissolved in EtOH (10 mL) was added to the previous solution. After 1 or 2 months of slow evaporation, yellow crystals were filtered and washed with CH₃CN. Yield: 46%. C₇₂H₅₈Mn₃N₄O₁₈ (M.W. = 1432.06 g mol⁻¹). Anal. Calcd (%): C, 60.67; H, 4.08; N, 3.91. Found (%): C, 58.98; H, 4.18; N, 4.05. IR (cm⁻¹): 3433 (br), 3068 (w), 2999 (w), 2929 (w), 2828 (w), 1600 (m), 1568 (s), 1540 (s), 1516 (m), 1451 (m), 1395 (s), 1314 (w), 1282 (w), 1242 (m), 1106 (w), 1042 (m), 904 (w), 849 (m), 764 (m), 727 (m), 669 (w), 637 (w), 533 (w).

[Mn₃(μ-4-MeOC₆H₄COO)₆(phen)₂]·EtOH (14). Mn(4-MeOC₆H₄COO)₂·2H₂O (0.12 mmol, 0.42 g) was dissolved in a mixture of EtOH (15 mL) and H₂O (5 mL). Then, phen (0.078 mmol, 0.015 g) dissolved in EtOH (10 mL) was added. The resulting pale yellow solution was stirred for 10 minutes and filtered to separate any possible impurity. After two months of slow evaporation, yellow crystals were filtered and washed with EtOH. Yield: 44%. C₇₂H₅₈Mn₃N₄O₁₈·EtOH (M.W. = 1478.13 g mol⁻¹). Anal. Calcd (%): C, 60.13; H, 4.36; N, 3.79. Found (%): C, 60.12; H, 4.46; N, 3.87. Physical characterisation

C, H and N analyses were carried out by the “Centres Científics i Tecnològics” of the Universitat de Barcelona. Infrared spectra were recorded on KBr pellets in the 4000–400 cm⁻¹ range with a Thermo Nicolet Avatar 330 FTIR spectrometer. Magnetic measurements were performed on microcrystalline samples in a Quantum Design MPMS XL5 SQUID Magnetometer at the “Unitat de Mesures Magnètiques” (Universitat de Barcelona). Magnetic susceptibility was measured between 2 and 300 K with a magnetic field of 0.02 T. Magnetisation measurements were performed at 2 K from 0 to 5.0 T. Pascal’s constant was used to estimate the diamagnetic corrections for the compound. The fit of the experimental magnetic data was performed by minimizing the func-

tion $R = \sum[(\chi_{\text{MT}}T)_{\text{exp}} - (\chi_{\text{MT}}T)_{\text{calcd}}]^2 / \sum[(\chi_{\text{MT}}T)_{\text{exp}}]^2$. Solid-state EPR spectra were recorded at X-band (9.4 GHz) frequency using a Bruker ESP-300E spectrometer from room temperature to 4 K at the “Unitat de Mesures Magnètiques” (Universitat de Barcelona).

Single-crystal X-ray crystallography

The data collection for compounds **2**, **6**, **7**, **8** (at 90–100 K), **5**, and **9** (at 302 K) was performed on a Bruker Apex-II diffractometer, whereas for **1**, **3**, and **12**, it was performed at room temperature on a MAR345 diffractometer, both equipped with graphite monochromatic Mo K α radiation ($\lambda = 0.71073$ Å). Unit-cell parameters were determined using 230–9972 reflections and refined by the least-squares method. 6090–127 139 reflections were collected using the Φ - and ω -scan (Bruker Apex-II) or Φ -scan (MAR345) method. Data were corrected for absorption effects using multi-scan (**2**, **6**, **8**, **7**, **5**, and **9**) or empirical (**1**, **3**, and **12**) methods (SADABS).²⁸ Tables containing crystallographic data collection and structure refinement details are summarised in the ESI (Tables S1–S3†).

The structures were solved by direct methods and refined by full-matrix least-squares using SHELXL-97.²⁹ Non-hydrogen atoms were refined anisotropically, whereas hydrogen atoms were computed and refined with isotropic thermal parameters riding on their respective carbon or oxygen atoms. The crystal structures of compounds **1**, **3**, **5**, and **12** were isotropically refined without any complication, but they showed high R_1 and wR_2 values and, in some cases, the presence of spurious peaks very close to other atoms. These peaks not only complicate the refinement of the anisotropic displacements but also altered the results. Therefore, the reflections showing high standard deviations were removed from the *hkl* files of **1**, **3**, **5**, and **12**, enabling us to better refine the structures and providing much better results. Even though some reflections were removed, the relationship between parameters to refine and reflections were more than enough to refine the structure in an appropriate way.

Compounds **1**, **3**, **5**, and **6** crystallise in the triclinic space group $P\bar{1}$. The asymmetric unit consists of half a $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-n-RC}_6\text{H}_4\text{COO})_2]^{2+}$ complex and one ClO_4^- anion. The other half of the complex is generated by an inversion centre. Around 400 parameters were refined in the final cycle of refinement on F^2 using no more than 15 restraints.

Compound **2** crystallises in the monoclinic space group $P2_1/c$. The asymmetric unit consists of half a $[\{\text{Mn}(\text{bpy})_2\}_2(\mu\text{-3-MeOC}_6\text{H}_4\text{COO})_2]^{2+}$ complex and a ClO_4^- anion. The other half of the complex is generated by an inversion centre. A total of 370 parameters were refined in the final cycle of refinement on F^2 without using any restraint.

Compound **7** crystallises in the monoclinic space group $C2/m$. The asymmetric unit consists of a fourth part of a $[\{\text{Mn}(\text{phen})_2\}_2(\mu\text{-4-MeOC}_6\text{H}_4\text{COO})_2]^{2+}$ complex and half a ClO_4^- anion. The rest of the complex is generated by an inversion centre and a mirror plane. A total of 239 parameters were refined in the final cycle of refinement on F^2 using 36 restraints.

Compound **8** crystallises in the triclinic space group $P\bar{1}$. The asymmetric unit consists of a $[\text{Mn}(\text{H}_2\text{O})(3\text{-MeOC}_6\text{H}_4\text{COO})(\text{phen})_2]^+$ complex and a ClO_4^- anion. A total of 424 parameters were refined in the final cycle of refinement on F^2 without using any restraint.

Compound **9** crystallises in the monoclinic space group Cc . The asymmetric unit consists of four slightly different complexes with the formula $[\text{Mn}(\text{H}_2\text{O})_2(2\text{-MeOC}_6\text{H}_4\text{COO})_2(\text{phen})]$. The H atoms of the water ligands were fixed in logical positions considering the plausible H bonds, with isotropic thermal parameters riding on their respective O atoms. A total of 448 parameters were refined in the final cycle of refinement on F^2 without using any restraint.

Single crystals of the mononuclear compound **10** were isolated and mounted on a diffractometer. However, the crystals were very thin, so they did not provide good diffraction frames and the structure could not be determined.

Compound **12** crystallises in the triclinic space group $P\bar{1}$. The asymmetric unit consists of half a $[\text{Mn}_3(\text{bpy})_2(\mu\text{-}4\text{-MeOC}_6\text{H}_4\text{COO})_6]$ complex. The rest of the complex is generated by an inversion centre. A total of 448 parameters were refined in the final cycle of refinement on F^2 without using any restraint.

Results and discussion

Synthesis

The reaction between Mn^{II} salts, carboxylate ligands, and nitrogen-based ligands (NN) is well described in the literature.^{26,27,30–42} As a function of the Mn^{II} :carboxylate:NN ratio, the solvent, the presence or absence of certain counter-anions, and the degree of deprotonation of some ligands, different kinds of compounds with diverse nuclearity can be obtained consisting of ionic or neutral complexes. Moreover, carboxylate ligands can display a wide number of coordination modes.

In this work, the reaction between the corresponding Mn^{II} carboxylate, $\text{Mn}(n\text{-RC}_6\text{H}_4\text{COO})_2$ ($n\text{-R} = 2\text{-MeO}, 3\text{-MeO}, 4\text{-MeO}$, and $4\text{-}^t\text{Bu}$), and a bidentate nitrogen-based ligand (NN), 2,2'-bipyridine (bpy) or 1,10-phenanthroline (phen), led to the formation of seven ionic dinuclear (**1–7**), three mononuclear (ionic, **8**, or neutral, **9** and **10**), and four neutral trinuclear (**11–14**) compounds. The kinds of compounds obtained for each couple of ligands are summarised in Table 1. Fig. 1

Fig. 1 Diagram showing compounds formed depending on the reagents, stoichiometry, and the solvent.

shows a concise diagram of the reactions and the obtained compounds, depending on the presence or absence of ClO_4^- ions and the solvent used when these were determining factors.

When NaClO_4 was added besides the Mn^{II} carboxylate and the NN ligand, ionic dinuclear compounds with the formula $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2][\text{ClO}_4]_2$ (**1–3**, with NN = bpy; **4–7**, with NN = phen) were obtained. It was not possible to obtain this kind of compound for $n\text{-R} = 4\text{-}^t\text{Bu}$ and NN = bpy. In most cases, the use of CH_3CN or EtOH led to the formation of the same compound. However, for $n\text{-R} = 3\text{-MeO}$ and NN = phen, a mononuclear compound with the formula $[\text{Mn}(\text{H}_2\text{O})(3\text{-MeOC}_6\text{H}_4\text{COO})(\text{phen})_2][\text{ClO}_4]$ (**8**) was obtained in these solvents in the presence of a small amount of water. The formation of the dinuclear compound **6** (3-MeO/phen) was only attained in MeOH.

As reported previously, when no perchlorate salt is added, neutral compounds of different nuclearities could be obtained as a function of the Mn:NN ratio (3:2 or 1:1) and/or solvent.^{27,30} With the manganese carboxylates used in this work, the Mn:NN ratio and the solvent (CH_3CN or EtOH) made no difference in the type of product that was formed, but they did for the conditions of crystallisation (time, crystallinity, etc.) and/or the purity of the sample. For instance, nice

^a Compounds from which the crystal structures have been determined.

yellow crystals of **9** were obtained in EtOH, while the sample contaminated with some brown product precipitated in CH₃CN. All attempts to obtain some neutral compounds with n -R = 2-MeO and NN = bpy were unsuccessful; nevertheless, when NN = phen, the mononuclear compound **9** was obtained. Similarly, for n -R = 4-^tBu and NN = bpy, a mononuclear compound was obtained (**10**), while we did not succeed in establishing any reproducible synthesis using phen. The formation of trinuclear compounds was attained when n -R = 3-MeO and 4-MeO with both NN ligands.

The presence of water in the reaction medium was required in nearly all cases, since it assists the dissolution of the Mn^{II} carboxylates. Nevertheless, H₂O also guaranteed the formation of the dinuclear compounds **3** and **5** because it prevented the fast precipitation of the corresponding neutral compounds, observed after several minutes of stirring when no additional H₂O was added.

Regarding the dinuclear compounds, two different coordination modes of the carboxylate ligands can be found, even though the synthetic method is the same. Fortunately, these coordination modes can be easily differentiated with the 1620–1300 cm^{−1} window of the IR spectra of these compounds. Although the nitrogen-based ligands (bpy and phen) show some bands in this region, it is possible to identify the two characteristic bands of the carboxylate groups, assigned to the asymmetric (ν_a) and symmetric (ν_s) vibrations. Values of $\Delta\nu = \nu_a(\text{COO}) - \nu_s(\text{COO}) < 200 \text{ cm}^{-1}$ indicate that the carboxylate ligands show a $\mu_{1,3}$ -coordination mode, whereas values of $\Delta\nu > 200 \text{ cm}^{-1}$ are indicative of a $\mu_{1,1}$ -coordination mode.^{26,43} For compounds **1**–**5**, the bands assigned to the carboxylate ligands arise at ~ 1550 and $\sim 1390 \text{ cm}^{-1}$, with $\Delta\nu \approx 160 \text{ cm}^{-1}$, consistent with a $\mu_{1,3}$ -coordination mode. In contrast, **6** and **7** show two bands at ~ 1570 and $\sim 1310 \text{ cm}^{-1}$ (with $\Delta\nu \approx 260 \text{ cm}^{-1}$), consistent with a $\mu_{1,1}$ -coordination mode.

The reason why one type of bridge is preferentially formed is very difficult to rationalise. As explained by Gómez *et al.*, two factors could contribute to this different behaviour: the steric and the electronic effects. In the referred work, only compounds containing phen and the R group in *meta* or *para* position show a $\mu_{1,1}$ -coordination mode.²⁶ Compounds with R = MeO follow the same tendency: while compounds **6** and **7**, with the respective n -R = 3-MeO and 4-MeO, have $\mu_{1,1}$ -bridges, compound **4**, with n -R = 2-MeO, exhibits a $\mu_{1,3}$ -coordination mode. However, compound **5** (n -R = 4-^tBu), whose carboxylate shows a $\mu_{1,3}$ -coordination mode, does not follow the expected trend. The cause of this variation may lie in the presence of the highly voluminous ^tBu group that, in spite of being in *para* position, can be the source of steric hindrance. Indeed, the formation of the $\mu_{1,1}$ -bridge shortens the Mn...Mn distance from ~ 4.65 (for a $\mu_{1,3}$ -bridge) to $\sim 3.46 \text{ \AA}$, also setting the facing phen ligands closer (see below).

Description of structures

Dinuclear compounds with $\mu_{1,3}$ - n -RC₆H₄COO[−] bridges (1, 2, 3, and 5). Compounds **1**, **2**, **3**, and **5** show an analogous structure, consisting of a cationic complex with the formula

$[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2]^{2+}$ and two perchlorate anions. To exemplify, Fig. 2 shows the crystal structure of the cationic complex of one of them (**3**). Those of compounds **1**, **2**, and **5** are found in the ESI (Fig. S1†). Selected interatomic distances and angles are listed in Table S4.†

The two Mn^{II} ions are bridged by two $\mu_{1,3}$ - n -RC₆H₄COO[−] ligands in *syn-anti* mode, with Mn...Mn distances ranging from 4.54 to 4.75 Å. The hexacoordination of each Mn ion is completed by two bpy (**1**, **2** and **3**) or phen (**5**) ligands. The Mn–O and Mn–N distances are in the ranges 2.09–2.14 Å and 2.26–2.36 Å, respectively, leading to distorted octahedral environments around the Mn^{II} ions. All these structural parameters are in agreement with those reported for analogous compounds.^{26,30–34,44,45}

Dinuclear compounds with $\mu_{1,1}$ - n -RC₆H₄COO[−] bridges (6 and 7). Compounds **6** and **7**, with the formula $[\{\text{Mn}(\text{phen})_2\}_2(\mu\text{-}n\text{-MeOC}_6\text{H}_4\text{COO})_2](\text{ClO}_4)_2$, display a very similar structure. Fig. 3 shows the crystal structure of the cationic

Fig. 2 Crystal structures of the cationic complexes of compound **2**, showing the anisotropic displacements as ellipsoids at 50% probability. Hydrogen atoms are omitted for clarity.

Fig. 3 Crystal structures of the cationic complexes of compounds **6**, showing the anisotropic displacements as ellipsoids at 50% probability. Hydrogen atoms are omitted for clarity.

complex of compound **6**. That of **7** may be found in the ESI (Fig. S2†). Selected interatomic distances and angles are listed in Table S5.†

The two Mn^{II} ions are linked through two $\mu_{1,1}$ - n - $\text{RC}_6\text{H}_4\text{COO}^-$ bridges, with $\text{Mn}\cdots\text{Mn}$ distances of ~ 3.45 Å. Two phen ligands are linked to each Mn^{II} ion, leading to distorted octahedral geometry. The $\text{Mn}-\text{O}$ distances are in the range 2.16–2.18 Å while the $\text{Mn}-\text{N}$ are 2.26 Å. The Mn_2O_2 ring is planar, and the $\text{Mn}-\text{O}-\text{Mn}$ ring is close to 105° . The structural parameters for compounds **6** and **7** are in agreement with those reported for analogous compounds with the $[\text{Mn}_2(\mu_{1,1}\text{-R}'\text{CCO})_2]^{2+}$ core.^{26,35,36,46}

In these compounds the phenyl ring and the carboxylate groups of the benzoate derivative bridge are almost coplanar and are perpendicular to the Mn_2O_2 ring. As may be seen comparing the structures of compounds containing $\mu_{1,3}$ - and $\mu_{1,1}$ -bridges (Fig. 2 and 3, respectively), the shorter $\text{Mn}\cdots\text{Mn}$ distance in the latter keeps the NN ligands closer to the aromatic ring of the carboxylate bridge and, consequently, this aromatic ring, which is found between two phen ligands, is forced to twist and become placed almost parallel to these ligands. For compounds **6** and **7**, the R group (3-MeO and 4-MeO, respectively) remains in the same plane as the phenyl ring, so their presence does not disturb the formation of the $\mu_{1,1}$ -bridges. On the other hand, the bulky $t\text{Bu}$ group has two methyl groups that stand out from the plane of the phenyl group, being able to cause steric hindrance. Hence, the formation of a dinuclear compound with $\mu_{1,1}$ -4- $t\text{BuC}_6\text{H}_4\text{COO}^-$ bridges could be tentatively considered improvable. The obtained dinuclear compound with this ligand shows $\mu_{1,3}$ -bridges (**5**).

Mononuclear compounds (8–10). Fig. 4 shows the crystal structure of the two mononuclear compounds with 3-MeO (**8**) and 2-MeO (**9**) benzoate derivatives. Selected structural parameters are listed in Table S6.†

The structure of compound **8** consists of a cationic complex with the formula $[\text{Mn}(\text{H}_2\text{O})(3\text{-MeOC}_6\text{H}_4\text{COO})(\text{phen})_2]^+$ and a perchlorate anion. The carboxylate ligand is coordinated in a

monodentate mode, with $\text{Mn}-\text{O}$ distances of ~ 2.15 Å. There are hydrogen bonds between the H_2O molecule and the hanging oxygen atom of the carboxylate ligand (O2). The hexacoordination of the Mn^{II} ion is completed by two phen ligands, with $\text{Mn}-\text{N}$ distances of ~ 2.26 Å. The structure of compound **9** comprises four neutral complexes with the formula $[\text{Mn}(\text{H}_2\text{O})_2(2\text{-MeOC}_6\text{H}_4\text{COO})_2(\text{phen})]$ with very similar structural parameters (Fig. S3 and Table S7†). Fig. 4 and Table S6† only concern the structure of one of these complexes. In this compound, the two carboxylate ligands are coordinated in monodentate mode. Each hanging oxygen atom of these ligands is interacting with one of the H_2O molecules through hydrogen bonds. The hexacoordination of the Mn^{II} ion is completed by one phen ligand, with $\text{Mn}-\text{N}$ distances of ~ 2.28 Å. The Mn^{II} ions in these compounds show a distorted octahedral geometry.

Crystals of compound **10** were poorly diffracting and its crystal structure could not be refined. However, some atoms could be assigned to several Q peaks. Apparently, the structure of this compound consists of a neutral complex with the formula $[\text{Mn}(\text{bpy})(4\text{-}^t\text{BuC}_6\text{H}_4\text{COO})_2]$, where the carboxylate ligands are coordinated in bidentate mode.

Trinuclear $[\text{Mn}_3(\text{bpy})_2(\mu\text{-}4\text{-MeOC}_6\text{H}_4\text{COO})_6]$ compound (12). The structure of compound **12** is shown in Fig. 5. Selected interatomic distances and angles are listed in Table S8.†

The structure of this compound consists of three Mn^{II} ions in a linear array, where the central Mn ion is located at a crystallographic inversion centre. This central ion (Mn2) is coordinated by six oxygen atoms of six 4-methoxybenzoate ligands and is linked to each terminal Mn ion (Mn1) through three 4-methoxybenzoate ligands, with $\text{Mn}\cdots\text{Mn}$ distances of ~ 3.60 Å. While two of these ligands link the Mn ions with both oxygen atoms ($\mu_{1,3}$) in a *syn-syn* mode, the third one links them through just one oxygen atom ($\mu_{1,1}$). The $\text{Mn}-\text{O}$ distances range from 2.15 to 2.25 Å. The other oxygen atom (O2) of this latter ligand is weakly bonded to the terminal Mn ion, with

Fig. 4 Crystal structures for the cationic complex of **8** and for one of the subunits of compound **9**, showing the anisotropic displacements as ellipsoids at 50% probability.

Fig. 5 Crystal structure of compound **12**, showing the anisotropic displacements as ellipsoids at 50% probability. Hydrogen atoms are omitted for clarity.

Mn–O distances of 2.33 Å. The hexacoordination of the terminal ions is completed by a phen ligand, with Mn–N distances of ~2.27 Å. These structural parameters are in agreement with those reported for analogous compounds.^{27,30,37–42}

The terminal Mn ions show a substantial elongation in the direction of the $\mu_{1,1}$ bridge. The central ion, in spite of having angles of 180° between facing bonds, displays a certain elongation in the direction of the $\mu_{1,1}$ bridge.

Magnetic properties

Magnetic susceptibility data were recorded for all polynuclear compounds (1–7 and 11–14) from room temperature to 2 K. Magnetisation measurements were performed at 2 K from 0 to 5.0 T for the compounds having $S \neq 0$ ground states (6, 7 and 11–14).

Dinuclear $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2](\text{ClO}_4)_2$ compounds (1–7). $\chi_{\text{M}}T$ versus T plots for the dinuclear compounds are represented in Fig. 6 and S4.†

$\chi_{\text{M}}T$ values at room temperature are close to the value expected for two uncoupled Mn^{II} ions. Two different behaviours may be found: (a) for compounds with $\mu_{1,3}$ -bridges (1–5), $\chi_{\text{M}}T$ values decrease as the temperature falls, indicative

of an antiferromagnetic behaviour; (b) for compounds with $\mu_{1,1}$ -bridges (6 and 7), $\chi_{\text{M}}T$ values increase as the temperature falls, indicative of a ferromagnetic behaviour. For these compounds, the $S = 5$ ground state is confirmed by the field dependence of the magnetisation at 2 K (inset of Fig. 6b), which shows $M/N\mu_{\text{B}}$ values consistent with 10 unpaired electrons.

$\chi_{\text{M}}T$ versus T plots were fitted using the PHI program, which uses the Hamiltonian $H = -2JS_1S_2$.⁴⁷ The results of the fit are collected in Table 2. The two ferromagnetic compounds (6 and 7) were fitted taking into account intermolecular interactions (zJ'), which improved the fit and reproduced the slight decrease of the $\chi_{\text{M}}T$ values below 2.5 K.

These results are in accord with the study reported by Gómez *et al.*, where analogous compounds containing $\mu_{1,3}$ - $n\text{-RC}_6\text{H}_4\text{COO}^-$ bridges show antiferromagnetic interactions whereas those with $\mu_{1,1}$ - $n\text{-RC}_6\text{H}_4\text{COO}^-$ bridges display ferromagnetic interactions.²⁶ The ferromagnetic interaction mediated by the $\mu_{1,1}$ -bridge is principally observed in Mn^{II} compounds having Mn–($\mu_{1,1}$ -O)–Mn angles of around 104°. However, other compounds with Mn–O–Mn angles ranging from 104° to 108° displaying antiferromagnetic behaviour have been reported.^{35,36,46}

Trinuclear $[\text{Mn}_3(\text{NN})_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_6]$ compounds (11–14). $\chi_{\text{M}}T$ versus T plots for the trinuclear compounds are represented in Fig. 7. At 300 K, $\chi_{\text{M}}T$ values are close to the expected value for three uncoupled Mn^{II} ions. As the temperature decreases, $\chi_{\text{M}}T$ values fall until reaching ~4.5 $\text{cm}^3 \text{mol}^{-1}$ K at 2 K, which is very close to the expected value for an $S = 5/2$ ground state (4.36 $\text{cm}^3 \text{mol}^{-1}$ K). This behaviour is indicative of an antiferromagnetic behaviour. The $S = 5/2$ ground state is confirmed by the field dependence of the magnetisation at 2 K (inset of Fig. 7), which shows $M/N\mu_{\text{B}}$ values consistent with 5 unpaired electrons.

$\chi_{\text{M}}T$ versus T plots were fitted with the PHI program⁴⁷ considering the Hamiltonian $H = -2J(S_1S_2 + S_2S_3) - 2J_{13}(S_1S_3)$ (see Fig. 8), where it is assumed that $J_{13} = 0$ due to the large Mn...Mn distance between the terminal ions (~7.2 Å). The results of these fits are collected in Table 3, these being consistent with those found in the literature for analogous trinuclear compounds.^{27,30,37–42} Moreover, the results obtained

for 12, with a marked $\mu_{1,1}$ -mode of the carboxylate bridge and a weak antiferromagnetic interaction ($2J = -2.5 \text{ cm}^{-1}$), are in agreement with the magneto-structural correlations previously reported.²⁷ However, the structural data of the compounds reported here are too scarce to provide new insights into these correlations, since only the crystal structure of compound 12 could have been determined.

EPR spectroscopy

The X-band EPR spectra of all Mn^{II} compounds herein reported (1–14) were recorded on powdered samples at different temperatures. At room temperature, all of them show a band centred at $g \approx 2$; however, the spectra become more complicated as the temperature falls. To exemplify, Fig. 9 shows the spectra at different temperatures for a dinuclear (5, 4-^tBu/phen) and a trinuclear (12, 4-MeO/bpy) compound.

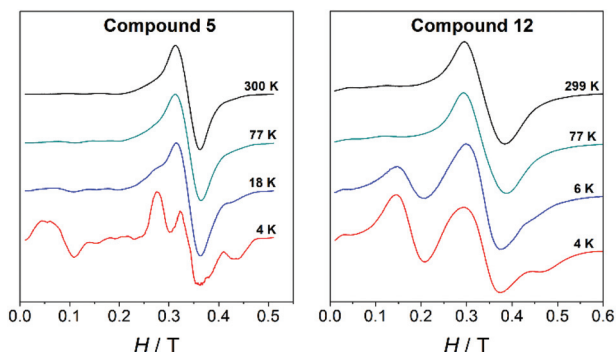

Fig. 9 Variable-temperature X-band EPR spectra for the dinuclear compound 5 and the trinuclear compound 12.

At 4 K, the spectra of each type of compound show peculiar features that allow its identification.

The fit of the EPR spectra was performed with the PHI program.⁴⁷ It is worth noting that, even though this program is able to fit EPR spectra, the initial values from which the fit will begin are of importance for the final result. Hence, we performed several simulations screening different D and E values, within the logical range that one may expect for hexacoordinated Mn^{II} ions, in order to choose the best initial values. All spectra were fitted considering a linewidth between 1.0 and 1.8 cm^{-1} .

Mononuclear compounds (8–10). The EPR spectra at 4 K of the mononuclear compounds (8–10) are shown in Fig. 10. As may be observed, they show some differences.

The three compounds display a broad and intense band at $g \approx 2$ and more features more or less pronounced at lower

Fig. 10 X-band EPR spectra for the mononuclear compounds 8, 9, and 10 at 4 K. The dashed lines correspond to the best fit of the experimental data.

fields. These spectra were fitted with the PHI program⁴⁷ considering a high-spin Mn^{II} ion and the single-ion ZFS parameters (D_{Mn} and E_{Mn}). The results from these fits are listed in Table 4.

The D_{Mn} values obtained from these fits are consistent with Mn^{II} ions with distorted octahedral geometry.²⁴ Several simulations were performed by changing the sign of D_{Mn} and E_{Mn} . While the shape of the spectra only depends on the $|E_{\text{Mn}}|$, they vary with the sign and magnitude of D_{Mn} . However, such differences were too small to unambiguously establish the sign of this parameter.

Dinuclear $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2](\text{ClO}_4)_2$ compounds (1–7). For the dinuclear compounds the shape of the EPR spectra at low temperature depends on their magnetic behaviour (Fig. 11 and 12). While ferromagnetic compounds display a broad and intense signal at $g \approx 2$ at different temperatures, the antiferromagnetic compounds show much more complex spectra and their shape is very sensitive to temperature (Fig. S5†). These latter compounds show an $S = 0$ ground state, so they are expected to be EPR silent. However, the small J values allow the lowest excited states, $S = 1$ and $S = 2$, to be populated at 4 K.

Table 4 Results from the fit of the EPR spectra of the three mononuclear compounds

Fig. 12 X-band EPR spectra for the antiferromagnetic dinuclear compounds 1–5 at 4 K. The dashed lines correspond to the best fit of the experimental data.

The cause of the difference between the EPR spectra of anti- or ferromagnetic compounds relies on the values of the zero-field splitting parameters, $|D_S|$ and $|E_S|$, of the states populated at low temperature. In fact, $|D_S|$ and $|E_S|$ become smaller as the spin increases.⁴⁸ Accordingly, the zero-field splitting parameters of the $S = 5$ ground state of the ferromagnetic compounds are much smaller than those of the first excited states, $S = 1$ and $S = 2$, of the antiferromagnetic compounds.

The EPR spectra at 4 K of the dinuclear compounds were fitted with the PHI program⁴⁷ with the aim of evaluating the single-ion ZFS parameters (D_{Mn} and E_{Mn}), considering two high-spin Mn^{II} ions, with either parallel or antiparallel disposition of their spin moments, using the magnetic coupling constant ($2J$) obtained from the fit of the magnetic data, and keeping $g = 2.00$. The results of these fits are collected in Table 5. Finding a good simulation of the EPR spectra of the

Table 5 Single-ion ZFS parameters obtained from the fit of the EPR spectra of the dinuclear compounds with the formula $[\{\text{Mn}(\text{NN})_2\}_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_2](\text{ClO}_4)_2$

dinuclear compounds was far more complicated than that for the mononuclear ones. Indeed, before starting the fits, it was necessary to perform several simulations screening different D_{Mn} and $E_{\text{Mn}}/D_{\text{Mn}}$ values in order to find the best initial values for the fits.

For the ferromagnetic compounds **6** and **7**, which display a single broad band (Fig. 11), the anisotropy parameters could not be determined with accuracy and, consequently, the results are expressed as a range. As mentioned above, the $D_{S=5}$ and $E_{S=5}$ parameters are smaller than the respective $D_{S<5}$ and $E_{S<5}$ for the same D_{Mn} and E_{Mn} .⁴⁸ Hence, the EPR spectra at low temperature of a ferromagnetic Mn^{II} compound, with $S = 5$ ground state, will be much less sensitive to the ZFS parameters of the Mn^{II} ions than the antiferromagnetic ones, where the first excited states, $S = 1$ and $S = 2$, are responsible for the splitting in the EPR signal. Indeed, while $D_{S=5} \approx 0.44D_{\text{Mn}}$, $D_{S=1} \approx -6.4D_{\text{Mn}}$ and $D_{S=2} \approx -0.95D_{\text{Mn}}$.⁴⁸ The D_{Mn} values obtained from the fit of the experimental data at 4 K are rather small ($\leq 0.05 \text{ cm}^{-1}$). Aiming to see the accuracy of these results, the shape of the spectra with different D_{Mn} and $E_{\text{Mn}}/D_{\text{Mn}}$ values was explored. As expected, no significant differences were found by changing the sign of D_{Mn} . For $D_{\text{Mn}} = 0.12 \text{ cm}^{-1}$, strong bands are observed at low fields. When $D_{\text{Mn}} = 0.07 \text{ cm}^{-1}$, the most intense features appear at $g \approx 2$, but a simple band, like the one in the experimental spectra, is only found when $D_{\text{Mn}} \leq 0.5 \text{ cm}^{-1}$ (Fig. S6†). Hence, in spite of the small effect of D_{Mn} on $D_{S=5}$, we can confirm that these compounds possess small single-ion ZFS parameters, as indicated in Table 5.

For these ferromagnetic compounds (**6** and **7**), the shape of the spectra is similar at different temperatures, with an increase of 0.02 T in the linewidth from 77 K to 4 K. The simulation of the EPR spectra with the parameters obtained from the fit reproduces well the effect of temperature on the linewidth (Fig. S7†).

The spectra of compounds **1–5** at temperatures $>10 \text{ K}$ are rather similar; however, at 4 K significant differences can be observed (Fig. 12). These spectra can be separated into three regions: (a) below 0.2 T, where only **5** shows a significant band; (b) between 0.2–0.4 T, where compounds **1** and **2** show a unique broad band, while compounds **3–5** show two overlapped bands; and (c) above 0.4 T, where compounds **1**, **2**, and **5** show a well-defined band. Owing to the intrinsic complexity of these spectra, fitting these spectra was far more challenging. The assignment of a particular set of values to the parameters was not trivial either, since the simulations obtained from the fit are far from being perfect. However, after screening different D_{Mn} and E_{Mn} values within the expected range for Mn^{II} ions, the simulations presented in Fig. 12 correspond to those better representing the shape of the spectra.

Moreover, a surprising peculiarity was found: the sign of D_{Mn} was certainly relevant for the shape of the EPR spectra of compounds **3**, **4**, and **5**. A good fit of the EPR spectra of these compounds can only be attained with $D_{\text{Mn}} > 0$. These latter facts suggest that one may likely establish the sign of D_{Mn} in some precise situations. In order to understand the effect of

the sign of D_{Mn} on the resulting EPR spectra, several simulations were performed with $g = 2.00$ and $2J = -2.4 \text{ cm}^{-1}$ and two different D_{Mn} values and four different E_{Mn} values. Fig. 13 shows the spectra for these hypothetical dinuclear compounds.

As observed, for a “small” D_{Mn} value of 0.07 cm^{-1} , the distinction between the spectra simulated with positive (red) or negative (blue) D_{Mn} appears very difficult to accomplish, since the bands are more or less situated in the same position and only the intensity differs. On the other hand, for a higher value ($|D_{\text{Mn}}| = 0.12 \text{ cm}^{-1}$), the differences between the spectra with positive or negative D_{Mn} become greater, as the bands do not only have different intensities but also appear at different fields. However, such variances become thinner as E_{Mn} increases, showing almost identical spectra when $|E_{\text{Mn}}|/|D_{\text{Mn}}| = 0.33$. The sign of D_{Mn} is indeed very difficult to determine upon approaching the rhombic limit ($E/D = 0.33$).^{49–51} To sum up, the degree of divergence between the spectra with positive and negative D_{Mn} depends on the magnitude of this parameter and the $|E_{\text{Mn}}|/|D_{\text{Mn}}|$ ratio: (a) the higher the D_{Mn} becomes, the more different the spectra are; and (b) the higher the $|E_{\text{Mn}}|/|D_{\text{Mn}}|$ ratio is, the less distinctive the spectra become.

To understand the cause of these latter points, a deeper analysis of the EPR spectra and Zeeman plots was performed. Firstly, it is worth recalling two important points: (a) in terms of populations the most relevant states are those with $S = 0$ (ground state, which display no EPR transitions), $S = 1$ (first excited state), and $S = 2$ (second excited state), whose populations at 4 K are ~ 66 , ~ 28 , and $\sim 5\%$, respectively; and (b) when the axial anisotropy (D_{Mn}) becomes relevant the Zeeman plot in the z magnetic field direction is rather different from those in the y and x ones ($x = y \neq z$), so the resulting EPR spectra come from the addition of the permitted transitions of the three Zeeman plots.

Therefore, the Zeeman plots in the x/y and z magnetic field directions for a hypothetical Mn_2^{II} system with $2J = -2.4 \text{ cm}^{-1}$

Fig. 13 X-band EPR spectra for a hypothetical dinuclear compound with $g = 2.00$ and $2J = -2.4 \text{ cm}^{-1}$ for two different values of D_{Mn} and four different $|E_{\text{Mn}}|/|D_{\text{Mn}}|$ ratios. Red lines and blue lines correspond to the simulations performed with positive and negative D_{Mn} , respectively.

and $D_{\text{Mn}} = \pm 0.12 \text{ cm}^{-1}$ were simulated, and the expected transitions were marked according to the spectroscopic selection rules, $\Delta M_S = \pm 1$ and $\Delta S = 0$.⁵² It is worth noting that no mixture of M_S states coming from different S levels was observed for $H < 1.0 \text{ T}$, so the EPR signals should come from the transitions between M_S states within the same S level. To simplify, the Zeeman plots of the first and second excited states were extracted from that calculated for the entire system and presented in two separated figures (Fig. 14 and 15). Fig. 14

Fig. 14 Zeeman plots in the x/y (dashed lines) and z (straight lines) magnetic field directions for the first excited state ($S = 1$), extracted from a complete Zeeman plot calculated for a Mn^{II} system with $2J = -2.4 \text{ cm}^{-1}$ and positive (red) and negative (blue) ZFS ($D_{\text{Mn}} = \pm 0.12 \text{ cm}^{-1}$). The arrows point out the expected transitions in the X-band EPR spectra. The transitions coming from the x and y magnetic field directions are represented by thicker arrows than those from the z magnetic field direction because their contributions are double.

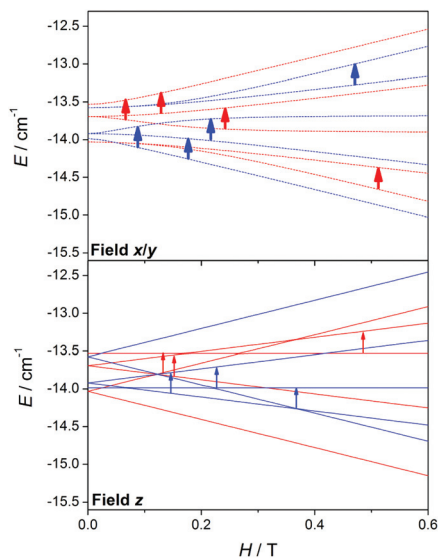

Fig. 15 Zeeman plots in the x/y (dashed lines) and z (straight lines) magnetic field directions for the second excited state ($S = 2$), extracted from a complete Zeeman plot calculated for a Mn^{II} system with $2J = -2.4 \text{ cm}^{-1}$ and positive (red) and negative (blue) ZFS ($D_{\text{Mn}} = \pm 0.12 \text{ cm}^{-1}$). The arrows point out the expected transitions in the X-band EPR spectra. The transitions coming from the x and y magnetic field directions are represented by thicker arrows than those from the z direction because their contributions are double.

shows the Zeeman plots in the x/y and z magnetic field directions of the first excited state, $S = 1$, for a Mn^{II} system with positive and negative D_{Mn} . The pointed transitions correspond to those having $\Delta M_S = 1$ (at $H = 0.5\text{--}0.6 \text{ T}$) and $\Delta M_S = 2$ (at $H \approx 0.2 \text{ T}$). These latter transitions should be forbidden according to the selection rules; however, when anisotropy is present, the M_S states mix and that allows these transitions.⁴⁸ As may be observed, the expected transitions should arise at the same field and should have the same intensity in both cases (for negative and positive D_{Mn}). Hence, the cause of the difference between these spectra should lie in the second excited state ($S = 2$).

Fig. 15 shows the Zeeman plots in the x/y and z magnetic field directions of the second excited state, $S = 2$, for a Mn^{II} system with positive and negative D_{Mn} . Contrary to the $S = 1$, the expected transitions coming from the $S = 2$ are rather different in both position and intensity as a function of the sign of D_{Mn} . These latter facts indicate that the differences between the spectra with positive and negative D_{Mn} rely on the transitions coming from the second excited state, $S = 2$.

Another arising question is what dictates the sign of D_{Mn} in Mn^{II} ions. As far as we know, there are several studies in the literature concerning the ZFS of Mn^{II} ions,^{24,50,51,53,54} however, the factors determining the sign of D_{Mn} still remain unknown.

Trinuclear $[\text{Mn}_3(\text{NN})_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_6]$ compounds (11–14). The EPR spectra of the trinuclear compounds (11–14) are very sensitive to temperature. The spectra recorded at room temperature show a very broad band centred at $g \approx 2$. This band generally remains the most intense signal until very low temperatures. At 4 K, the spectra of compounds 11, 12 and 14 become quite complicated: they show a new band at low field ($g \approx 4$), of similar or major intensity compared to the band at $g \approx 2$, and some other features at high field (Fig. 16). The EPR spectrum at 4 K for compound 13 is quite different from the rest, showing the most intense band at $g \approx 2$ and a smaller one at low field.

Fitting the EPR spectra of the trinuclear compounds considering the whole system would be much more time-consuming, since each iteration takes about half an hour. So, in this case, the ZFS of the Mn^{II} ions were not determined. As seen with the magnetic measurements, these compounds show an $S = 5/2$ ground state. The first and second excited states, $S = 3/2$ and $S = 7/2$, respectively, are found in the $5.5\text{--}7.3$ and $7.6\text{--}10 \text{ cm}^{-1}$ ranges, respectively, depending on the $2J$ values. At 4 K, the population of these states is quite low, being $6.5\text{--}11.2\%$ and $2.3\text{--}5.1\%$ for the respective $S = 3/2$ and $S = 7/2$ states. Hence, at this temperature, the greatest contribution to the EPR spectra will be the ground state, whose population ranges from ~ 80 to $\sim 90\%$.

Therefore, the spectra at 4 K were fitted using the PHI program⁴⁷ considering an isolated $S = 5/2$ spin state with axial ($D_{5/2}$) and rhombic ($E_{5/2}$) ZFS, keeping $g = 2.00$. Before fitting the experimental data, several simulations were carried out in order to identify which were the best initial values. The results of these fits, listed in Table 6, are in agreement with those reported for analogous compounds, whose $D_{5/2}$ and $E_{5/2}$ are

Fig. 16 X-band EPR spectra for the trinuclear compounds **11**, **12**, **13** and **14** at 4 K. The dashed lines correspond to the best fit of the experimental data considering an isolated $S = 5/2$ ground state.

Table 6 Results from the fit of the EPR spectra of the trinuclear compounds with the formula $[\text{Mn}_3(\text{NN})_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_6]$ considering an isolated $S = 5/2$ ground state

Compound	$ D_{5/2} /\text{cm}^{-1}$	$ E_{5/2} /\text{cm}^{-1}$	$ E_{5/2} / D_{5/2} $
11	0.14	0.040	0.28
12	0.14	0.046	0.33
13	0.045	0.015	0.33
14	0.14	0.046	0.33

~ 0.16 and $\sim 0.05 \text{ cm}^{-1}$, respectively.²⁷ Compound **13** displays much smaller ZFS parameters; however, the lack of structural data for this compound does not allow us to reach any conclusion. As observed in Fig. 16, only the fit for **13** corresponds to a good simulation of the experimental spectra. For the rest of the compounds, the theoretical graphs reproduce the band at 0.15 T, but they show significant differences in the other regions of the spectra. Particularly, the intensity of the band at $g \approx 2$ for compounds **11**, **12**, and **14** seems to be underestimated, since it is much weaker in the fitted spectra (red dashed lines) than in the experimental ones (black line). Nevertheless, one should remember that these fits have been performed considering just the ground state and the greater intensity of these bands may be due to the excited states.

To explain this, the Zeeman plot for this kind of trinuclear compound was simulated considering $|D_{\text{Mn}}| = 0.1 \text{ cm}^{-1}$ for the three Mn ions. The central ion, even though it is quite regular from the point of view of the angles (O6a–Mn2–O6, O4–Mn2–O4a, and O1–Mn2–O1a angles of 180°), shows a substantial elongation in the direction of the $\mu_{1,1}$ -carboxylate ligand. From

these calculations a relationship between the magnitudes of the ZFS parameters of each states could be found, where $D_{\text{Mn}} \approx 0.64 D_{5/2}$ and $D_{5/2} \approx 0.95 D_{3/2} \approx 6.2 D_{7/2}$. So, while the two first states will have very similar D , the second excited state ($S = 7/2$) has a much smaller D parameter. To confirm the effect of the population of the $S = 7/2$ state on the shape of the graph, a new simulation was carried out for a system with an $S = 7/2$ spin state, whose ZFS parameters are $D_{7/2} = 0.025 \text{ cm}^{-1}$ and $E_{7/2} = 0.0075 \text{ cm}^{-1}$ (equivalent to the fitted $D_{5/2}$ and $E_{5/2}$ parameters divided by 6). This spectrum displays just a broad and intense signal at $g \approx 2$. Hence, the higher intensity of this band in the experimental spectra of the trinuclear compounds may be due to a small contribution (population in the range 2.3–5.1%) of the second excited state ($S = 7/2$).

Simulations of the spectra of each compound were performed considering the entire molecule, including the magnetic coupling constant and the same D_{Mn} and E_{Mn} values for the three Mn(II) ions. D_{Mn} values were calculated from the $D_{5/2}$ values obtained from the fit (listed in Table 6), with the relationship obtained with the analysis of the Zeeman plots ($D_{\text{Mn}} = 0.64 D_{5/2}$) (see above). Moreover, we assumed that the $E_{\text{Mn}}/D_{\text{Mn}}$ ratio is similar to the $E_{5/2}/D_{5/2}$ ratio. The parameters used for these simulations are listed in Table 7. They were performed for two different temperatures (4 and 60–80 K), considering the same linewidth and ZFS parameters. Fig. 17 shows these simulations at 4 K. To exemplify, Fig. S8† shows the experimental spectra and simulations at 4 and 60 K for compound **11**.† From these simulations three remarkable conclusions could be drawn: (a) the simulation reproduces well the effect of temperature on the shape of the spectra; (b) no significant difference is observed by changing the sign of D_{Mn} ; and (c) the intensity of the bands at $g \approx 2$ for **11**, **12**, and **14** is well reproduced when the entire system is considered, confirming the contribution of the second excited state as suggested above.

As observed in Fig. 17, these simulations reproduce the experimental spectra much better. The differences between the spectra of **13** and the others (**11**, **12**, and **14**) are a consequence of the different D_{Mn} values, which are significantly smaller for **13**.

Even though the experimental spectra are much better reproduced when the entire system is considered and in spite of our efforts, the simulations for **12** and **14** show two bands,

Table 7 Parameters used for the simulation of the EPR spectra of the trinuclear compounds, with the formula $[\text{Mn}_3(\text{NN})_2(\mu\text{-}n\text{-RC}_6\text{H}_4\text{COO})_6]$, considering the entire trinuclear system

at 0.06 T and at 0.45 T, that are not present in the experimental ones. Aiming to find an explanation, four new simulations were performed with $2J = -2.0$ and -3.0 cm^{-1} , and D_{Mn} (E_{Mn}) = 0.09 (0.03), and 0.03 (0.01) cm^{-1} . From these simulations (presented in Fig. S9†) we concluded that: (a) the intensity of the bands at $g \approx 2$ decreases when the magnetic interaction is more antiferromagnetic; (b) the band at 0.15 T is intense when $D = 0.09 \text{ cm}^{-1}$ and is independent of the $2J$ value; (c) the shoulder at 0.25 T is only detectable with $D = 0.09 \text{ cm}^{-1}$; (d) the band at 0.45 T is well defined when $D_{\text{Mn}} = 0.09 \text{ cm}^{-1}$ and $E_{\text{Mn}} = 0.03 \text{ cm}^{-1}$; and (e) when $D = 0.03 \text{ cm}^{-1}$ the effect of the magnitude of the magnetic interaction is negligible.

With the aim of clarifying why the band at 0.45 T in the experimental spectra was not observed in the simulation, the effect of E_{Mn} was also analysed by performing simulations (shown in Fig. S10†) with the same $2J = -3.0 \text{ cm}^{-1}$ and $D_{\text{Mn}} = 0.09 \text{ cm}^{-1}$, and $E_{\text{Mn}} = 0.02, 0.025$, and 0.03 cm^{-1} . As may be observed, a small decrease of E_{Mn} changes the shape of the spectra substantially.

Conclusions

The reaction between $\text{Mn}(n\text{-RC}_6\text{H}_4\text{COO})_2$, where $n\text{-R} = 2\text{-MeO}$, 3-MeO , 4-MeO , or $4\text{-}^t\text{Bu}$, and the NN ligands bpy and phen led to the formation of seven ionic dinuclear, three mononuclear (ionic or neutral), and four trinuclear compounds. Each type of compound was formed depending on the presence or absence of ClO_4^- ions, the solvent used, and/or the presence

of a small amount of water in the reaction medium. Regarding the dinuclear compounds, two different types of complexes were obtained: those with $\mu_{1,1}$ -carboxylate bridges, which present ferromagnetic behaviour, and those having $\mu_{1,3}$ -carboxylate bridges, which show an antiferromagnetic interaction. The formation of compounds with the $\mu_{1,1}$ -carboxylate bridges occurs when the R group is in *meta* ($n = 3$) or *para* ($n = 4$) position and phen is the blocking ligand.²⁶ However, the voluminous $4\text{-}^t\text{Bu}$ group apparently hinders the formation of these $\mu_{1,1}$ -bridges.

The EPR spectra of each type of compound give some peculiar features that allow its identification. All the EPR spectra presented in this work have been fitted in order to obtain the ZFS parameters, D and E . However, fitting these spectra is not as easy as we expected, since many simulations had to be performed in order to choose the best initial values of the parameters willing to determine. In spite of these complications, fitting the spectra helped us to easily adjust the theoretical curves to the experimental ones after obtaining the approximate values.

The spectra of the antiferromagnetic dinuclear compounds are much more complex than those of the ferromagnetic ones, very likely because the ZFS parameter values of the states (D_S and E_S) populated at low temperature are higher for the antiferromagnetic systems. Moreover, the splitting of the bands in the antiferromagnetic compounds is eventually very sensitive to the sign of D_{Mn} , particularly when $D_{\text{Mn}} > 0.10 \text{ cm}^{-1}$ and the $|E_{\text{Mn}}|/|D_{\text{Mn}}|$ ratio is low. The analysis of the Zeeman plots revealed that the source of the difference between the spectra with positive and negative D_{Mn} lies in the second excited state ($S = 2$).

The shape of the EPR spectra at low temperature for the mononuclear and trinuclear complexes is different, in spite of showing the same $S = 5/2$ ground state. For the trinuclear compounds, the relative intensity of the bands depends on the population in the excited states. The influence of the population in the second excited state ($S = 7/2$) could be seen with the intensity of the band at $g \approx 2$; this state has much smaller ZFS parameters than the ground and first excited states and contributes to the intensity of this $g \approx 2$ band.

Contrary to the mono- and dinuclear compounds, the EPR spectra of the trinuclear ones were fitted just considering the ZFS of the ground state. A relationship between the ZFS parameters of the states and those of the Mn^{II} ion was then found from the analysis of the Zeeman plot of a trinuclear system. Therefore, the single-ion ZFS parameters could be estimated from those obtained just considering the ground state, giving a good simulation of the EPR spectra considering the entire system.
