Protein kinase B (PknB) is an essential serine/threonine protein kinase required for *Mycobacterium tuberculosis* (*M. tb*) cell division and cell-wall biosynthesis. A high throughput screen using PknB identified a (*E*)-4-oxo-crotonic acid inhibitor, named YH-8, which was used as a scaffold for SAR investigations. A significant improvement in enzyme affinity was achieved. The results indicated that the α,β-unsaturated ketone scaffold and "*trans*-" configuration are essential for the activity against PknB. And compounds with an aryl group, especially with electron-withdrawing substituents on benzene ring, exhibited four fold potency than that of **YH-8**.

1. Introduction

As an essential *Mycobacterium tuberculosis* (*Mtb*) serine/threonine protein kinase (STPK), protein kinase B (PknB) is highly conserved in Gram-positive bacteria and apparently required for mycobacterial growth.[1–4] The knockout and over-expression of PknB can lead to alteration of growth rate and cell morphology of TB.[5–8] The crystal structure of the kinase domain of PknB in complexes with an ATP analogue[9] exhibits less than 30% similarity with eukaryotic and prokaryotic STPKs, which suggests that PknB may be a potential drug target for the tuberculosis kinases and not those of the host. Previously many high affinity inhibitors have also been reported for PknB.[10]

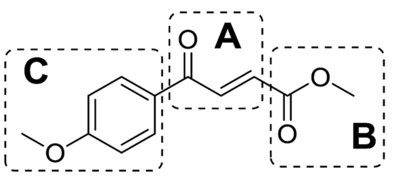

Fig. 1 The HTS hit **YH-8**.

YH-8, namely (*E*)-methyl-4-(4-methoxyphenyl)-4-oxobut-2-enoate (Fig. 1), was identified as a PknB inhibitor from a high throughput screen (HTS) of our compounds collection. Its majority anti-TB activity of minimum inhibitory concentrations (MICs) is falling in the 0.625–1.250 μmol L^{-1} range *in vitro*, which is significantly higher than other reported PknB inhibitors, such as amminopyrimidines, aminoguanidines and anthraquinones classes.[11] Stability assay revealed that **YH-8** was stable over 12 h in rat plasma samples, and the acute toxicity for the LD_{50} values in rat were 600 mg kg^{-1} (orally administered) and 200 mg kg^{-1} (vein injected).[12] As a new unsaturated crotonic acid scaffold of **YH-8** from all reported anti-TB chemical scaffolds,[10,13] the previously results formed the starting point for our chemistry programme. In this study, we reported on the synthesis and structure–activity relationship (SAR) study of series of **YH-8** derivatives as potential PknB inhibitors.

2. Chemical synthesis

In Scheme 1, 7 compounds were firstly designed and synthesized based on the scaffold A ((*E*)-α,β-unsaturated ketone, Fig. 1) of **YH-8** for SAR investigations. γ-Oxobenzenebutanoic acid **2a** was prepared using Friedel–Crafts acylation of anisole with succinic anhydride catalyzed by Lewis acid of aluminum chloride in 80% yield.[14] Reduction of **2a** by triethylsilane in trifluoroacetic acid obtained **3a** in 72% yield. Methyl esters **1b**, **2b** and **3b** were synthesized from corresponding acids **1a**, **2a** and **3a** in methanol catalyzed by concentrated sulfuric acid in 92–95% yields.[15] According to literature method,[16] the carboxylic acid group of **1a**, **2a** and **3a** was firstly activated by treatment with isobutylchloroformate (IBCF), the product of which was then treated *in situ* with ammonia gas at −15 °C to give corresponding amides **1c**, **2c** and **3c** in 75–85% yields. the 20 aromatic *E*-3-acylacrylic acid derivatives **7a–t** were directly prepared from corresponding ketones **6a–t** and glyoxylic acid in 50–75% yields.[17] Esters **8a–t**, **9a–t** and **10a–t** were obtained using the same method of **2a** in around 40% yield. The "*cis*-" configuration (**4**, (*Z*)-methyl 4-(4-methoxyphenyl)-4-oxobut-2-enoate) of **YH-8** (**8a**) was separated from a mixture of *cis*- and *trans*-products in 48% yield. Similarly, the carboxylic acid group of **7a–t** was firstly activated by treatment with IBCF, the product of which was then treated *in situ* with *N*-Boc-ethanolamine to afford compounds **11a–t** in 47–84% yields.

3. Results and discussion

As a promising PknB inhibitor, the structure of **YH-8** is markedly different from the reported PknB inhibitors. As shown in Fig. 1, **YH-8** was characterized as a substituted (*E*)-4-oxo-crotonic acid scaffold with three parts, namely A ((*E*)-α,β-unsaturated ketone), B (ester) and C (aryl). We presumed each part should play a different role of the interactions between **YH-8** and PknB ATP-binding site. In other words, firstly we should clarify which part is essential for the activity and which part is allowed to be modified for increasing potency. So, initial SAR study was performed mainly around the scaffold A ((*E*)-α,β-unsaturated ketone). As shown in Scheme 1-a, scaffold A was firstly deduced to methyl ester **1b** and amide **1c** from corresponding acid **1a**, which lacks a carbonyl (ketone) group comparing with the α,β-unsaturated ketone of A. In Scheme 1-b, the carbon–carbon double bond of scaffold A was deduced to an alkane acid **2a** by a Friedel–Crafts acylation reaction from anisole. The carbonyl (ketone) group of **2a** was sequentially reduced to methylene of **3a**. Both acids of **2a** and **3a** were also converted to corresponding methyl esters **2b** & **3b** and amides **2c** & **3c**. In Scheme 1-c, the "*cis*-" configuration (**4**) of **YH-8**, (*Z*)-methyl 4-(4-methoxyphenyl)-4-oxobut-2-enoate, was separated from a mixture of *cis*- and *trans*-products and characterized by ^{1}H NMR. The J_{HH} of "*cis*-" configuration is 3.6 Hz less than its "*trans*-" configuration. And the "*cis*-" configuration (**4**) is a yellow oil, whereas **YH-8**, namely **8a** in this study, is a yellow solid.

According to preliminary measurements, inhibitor concentration of 20 μM in the assay of percent inhibition of PknB was selected mainly because this concentration can cover and reflect the inhibitory rates rightly for all test compounds. Including carboxylic acid, esters and amides, ten compounds in Scheme 1 were tested for inhibitory activity against PknB at 20 μM along with **YH-8**. As shown in Table 1, eight compounds exhibit less than 10% inhibition against PknB comparing with **YH-8** (52.1%). Only compounds **1a** & **4** have a moderate inhibition (30.7% & 24.7%). The results show the α,β-unsaturated ketone

scaffold and "*trans-*" configuration are essential for the activity of **YH-8** against PknB.

Based on the findings above, the subsequent SAR study of **YH-8** was carried out on modification of part B and C while maintaining the α,β-unsaturated ketone scaffold and "*trans-*" configuration. As shown in Scheme 2, series of compounds were synthesized from corresponding methyl ketones (**6a–t**). The structures of **8a–t**, **9a–t**, **10a–t**, and **11a–t** were shown in Table 2 and their PknB inhibitory activities were listed in Table 3. The data indicated that almost half of the tested compounds have comparable activity against PknB comparing with **YH-8** (52.1%). Particularly, compounds **11a–t** bearing a *tert*-butoxycarbonylaminoethyl group on part B generally show higher potency than that of other series. Among them, **11n–p** exhibited much better activity (87.1%, 87.9% and 87.6%, respectively). Mostly, compounds bearing an aryl group on part C generally show higher potency than that substituted with alkyl analogues (**8r–t**, **9r–t**, **10r–t** and **11r–t**). It indicated that the alkyl group on part C would be detrimental to the activity. For the aryl substituted compounds, **8–11g** (61.4–70.7%) with 2,5-dimethoxyphenyl, **8–11h** (62.1–68.3%) with 3,4-dimethoxyphenyl, **8–11m** (61.3–73.6%) with naphthyl, **8–11n** (61.3–73.6%) except **9n** (49.0%) with 2,4-dichlorophenyl, **8–11o** (59.1–87.9%) with 4-nitrophenyl, **8–11p** (64.5–87.6%) with 4-bromophenyl and **8–11q** (60.8–67.0%) with furyl exhibit higher activity than **YH-8** of 52.1%. We speculated that the position of the substituted group on phenyl ring should be one of the factors that influence the binding between inhibitor and PknB ATP-binding site. Meanwhile, electron-withdrawing groups on phenyl ring should be beneficial to the potency. It maybe through the electron-withdrawing effect influence on the conjugation of scaffold A, which is known to be essential for the activity of **YH-8** against PknB above.

Finally, the 50% inhibition concentrations (IC_{50}) of compounds **11a–t** were tested in Table 4. Among them, compounds **11a–c**, **f**, **g**, **i**, **m–q** exhibit apparently higher IC_{50} activities than **YH-8**. Particularly, compounds **11n**, **11o** and **11p** (IC_{50}: 5.6 μM, 4.4 μM and 5.4 μM, respectively) with electron-withdrawing substituents on benzene ring show about four-fold more potent than that of **YH-8** (IC_{50}: 20.2 μM). Additionally, most IC_{50} values of compounds **11a–t** in Table 4 consistently match with the corresponding inhibitory rates in Table 3. For example, the inhibitory rates of compounds **11o**, **11p**, **11n**, **11f**, **11a**, **11e** and **11t** are 87.9%, 87.6%, 87.1%, 66.2%, 61.6%, 54.3% and 40.0%, respectively. And their corresponding IC_{50} values are 4.4, 5.4, 5.6, 10.5, 14.1, 19.1 and 38.4 μM, respectively.

4. Conclusions

In summary, the starting HTS hit of **YH-8** was optimized for potency against PknB, and total 87 compounds were synthesized for SAR investigations. The initial SAR study of **YH-8** indicated the α,β-unsaturated ketone scaffold and "*trans-*" configuration are essential for the activity of **YH-8** against PknB. According to this finding, other 80 **YH-8** derivatives were synthesized and evaluated. The results showed that the compounds bearing an aryl group on part C and a *tert-*

5. Experimental section

Methods and materials

The chemicals were purchased from Aldrich Chemical Co., Sigma or Chemical Co. THF was distilled under argon from sodium-benzophenone ketyl and CH_2Cl_2 was distilled under argon from calcium hydride. The reaction products were purified by crystallization or flash column chromatography using a mixture of petroleum ether and ethyl acetate as the eluent. All melting points were obtained on a Mettler Toledo Melting Point MP70 apparatus (Mettler Toledo, Zurich, Switzerland) and are uncorrected. ^{1}H-NMR spectra were recorded on Varian Inova-400 MHz, Varian Inova-500 MHz and SYS-600 MHz instruments (Varian, Palo Alto, CA, USA). The chemical shifts (δ) are reported in ppm relative to the internal reference standard tetramethylsilane (TMS) and the coupling constants (J values) have been reported in Hertz (Hz). MS data were obtained using time-of-flight mass spectrometer (TOF-MS) or Bruker microTOF-Q instrument (Bruker, Billerica, MA, USA). High resolution mass spectra (HRMS) were obtained on a Q-TOF Ultima ESI instrument (micrOTOF-Q II, Bruker Daltonics, Leipzig, Germany). Analysis by thin layer chromatography (TLC) was performed on silica gel plates (Merck, Billerica, MA, USA). Automated column chromatography was conducted over silica gel using a Companion Rf 200 automated chromatography system (Teledyne ISCO, Lincoln, NE, USA).

General synthetic procedures

Method A: general procedure for the preparation of esters (1b, 2b, 3b, 8a–t, 9a–t and 10a–t) from corresponding acids.[15] To a solution of the corresponding acid (1 equiv.) in corresponding alcohol (2 mL mmol^{-1}) was added concentrated sulfuric acid (25 μL mmol^{-1}). The reaction mixture was refluxed overnight, then cooled, concentrated, diluted with sat. $NaHCO_3$ solution, extracted with DCM, dried over Na_2SO_4 and concentrated in vacuum. The residue was purified by flash column chromatography on silica with an elution of hexanes/EtOAc 4 : 1 to give the corresponding ester.

Method B: general procedure for the preparation of amides (1c, 2c and 3c) from corresponding acids.[16] To a solution of the corresponding acid (1 equiv.) in anhydrous THF (5 mL mmol^{-1}) was added triethylamine (2 equiv.) under argon atmosphere, and cooled to −15 °C. Isobutylchloroformate (IBCF, 2 equiv.) was added dropwise at a rate so as to not exceed an internal temperature of −10 °C. After stirring for 1 h at −15 °C, ammonia gas was slowly bubbled into the reaction mixture. During the bubbling, the reaction temperature rose to 0 °C and kept the reaction temperature at 0 °C overnight. Then the reaction mixture was diluted with EtOAc (10 mL $mmol^{-1}$) and washed with 10% aqueous sodium chloride solution, followed by saturated brine. The organic layer was dried over Na_2SO_4. After filtration, the solvent was removed under reduced pressure to give the corresponding amide.

Method C: general procedure for the preparation of *E*-γ-oxo-α,β-alkenyl acids (7a–t).[17] To a solution of glyoxylic acid (**5**, 1 equiv.) in acetic acid (2 mL $mmol^{-1}$) was added corresponding methyl ketone (1 equiv.). The resulting mixture was refluxed for overnight and monitored by TLC using ethyl acetate/petroleum ether (2 : 1) as a solvent system. After cooling, the solvent was evaporated. The residue was washed with ice-cold water by decantation or on a filter. The crude product was dried in air at 40 °C and recrystallized from ethyl acetate or purified by column chromatography over silica gel with elution of a mixture of petroleum ether and ethyl acetate (2 : 1) to give the corresponding acid. For the synthesis of compound **7s**, catalytic amount of morpholine hydrochloride was used as a catalyst without acetic acid as a solvent at 120 °C for overnight.

Method D: general procedure for the preparation of *E*-γ-oxo-α,β-alkenyl acids (11a–t). To a solution of **7a–t** (1 equiv.) in anhydrous dichloromethane (10 mL $mmol^{-1}$) was added triethylamine (TEA, 2 equiv.), followed by the addition dropwise of isobutylchloroformate (IBCF, 1.5 equiv.) at −15 °C in nitrogen atmosphere. After the addition done, the resulting mixture was stirred at −15 °C for further 8 h. *N*-Boc-ethanolamine (0.8 equiv.) was added and the reaction mixture was stirred for overnight and allowed to warm to room temperature. The reaction mixture was washed sequentially by saturated aqueous ammonium chloride and saturated brine, dried over Na_2SO_4. After filtration, the solvent was removed under reduced pressure. The residue was purified by flash column chromatography on silica with an elution of hexanes/EtOAc 4 : 1 to give the corresponding ester.

In vitro protein kinase assay[12]

The inhibition rates and IC_{50} values of target compounds were determined by a non-radioactive assay using Promega 'Kinase Glo' plus Luminescent Kinase assay kit. The assay was carried out in a 96-well plate and the reaction mixture was prepared: 3 μM PknB[12] in buffer (25 mL Tris–HCl pH 7.4, 5 mM $MgCl_2$, 2 mM $MnCl_2$) containing the compound at various concentrations. Following inculation at 4 °C for 30 min, ATP was added to the reaction buffer at the final concentration of 100 μM, and the plates were conducted at 37 °C for 3 hours. Multilabel Plate Reader (PE Envision) was used to measure the intensity of luminescence signal with addition of 50 μL Kinase Glo reagent. The inhibition rates were calculated by the following formula and the IC_{50} values were calculated using the GraphPad Prism5 software.

$$\text{Inhibition rate (\%)} = \frac{\Delta\text{LN} - \Delta\text{LS}}{\Delta\text{LN} - \Delta\text{LP}} \times 100\%.$$

ΔLN: luminescence intensity of negative control; ΔLS: luminescence intensity of sample; ΔLP: luminescence intensity of positive control.
