Crystal structure, tunable luminescence and energy transfer properties of Na₃La(PO₄)₂:Tb³⁺,Eu³⁺ phosphors†

Dan Qin and Wanjun Tang*

A series of Tb^{3+} and/or Eu^{3+} doped $Na_3La(PO_4)_2$ phosphors were successfully synthesized and their crystal structure and photoluminescence (PL) properties were investigated in detail. Double phosphates with the compositions $Na_3Tb(PO_4)_2$ and $Na_3Eu(PO_4)_2$ were obtained by the substitution of Tb or Eu for La in the $Na_3La(PO_4)_2$ host. XRD pattern analysis indicates that these obtained compounds crystallize in the orthorhombic system with the space group $Pbc2_1$. The crystal structure of the $Na_3RE(PO_4)_2$ (RE = Tb, Eu) is made up of isolated PO_4 tetrahedra and of sodium and RE atoms arranged in an ordered way. The REO_y polyhedra are isolated from one another, resulting in a high critical concentration of Tb^{3+} or Eu^{3+} activators. Under excitation of near-ultraviolet (NUV) irradiation, Tb^{3+} doped $Na_3La(PO_4)_2$ shows a bluegreenish emission with a predominant peak at 546 nm, while the emission spectra of Eu^{3+} -doped $Na_3La(PO_4)_2$ exhibits a reddish orange emission due to the $^5D_0 \rightarrow ^7F_J$ transitions of Eu^{3+} ions. The energy transfer from Tb^{3+} to Eu^{3+} in the $Na_3La(PO_4)_2$ host is demonstrated by the luminescence spectra and fluorescence decay dynamics. Meanwhile, the emission color of $Na_3La(PO_4)_2$: Tb^{3+} , Eu^{3+} can be tuned from green to red through tuning the Tb^{3+}/Eu^{3+} ratio. These results indicate that the $Na_3La(PO_4)_2$: Tb^{3+} , Eu^{3+} phosphor exhibits broadband NUV absorption and green-reddish orange tunable emission, which might serve as a down-converting phosphor for NUV light-emitting diodes.

Introduction

Rare earth (RE) ions play an irreplaceable role in the development of lighting and display fields due to their abundant emission colors based on 4f-4f or 5d-4f transitions. 1-3 Recently, RE³⁺ ion doped phosphors based on double phosphate hosts have drawn much attention because of their high luminous efficiency, low sintering temperature, high thermal and chemical stability, and low cost. 4,5 Double phosphates of mono- and trivalent cations with the general formula $M^{I}_{3}N^{III}(PO_{4})_{2}$ ($M^{I}=$ Na, K; N^{III} = Y, Sc, In, Fe, rare earth elements) have high thermal and chemical stability and their host absorption edge locates at a rather short wavelength (about 140-180 nm).6 making them excellent host materials for luminescent materials. M₃N^{III}(PO₄)₂ compounds crystallize in a trigonal, orthorhombic or monoclinic structure, depending on the type of M^I or N^{III} cations.⁷ Among them, Na₃RE(PO₄)₂ (RE = La-Tb) compounds crystallize orthorhombic with the glaserite-type

Hubei Key Laboratory for Catalysis and Material Science, College of Chemistry and Material Science, South-Central University for Nationalities, Wuhan 430074, P. R. China. E-mail: tangmailbox@126.com; Fax: +86-27-67842752; Tel: +86-27-67842752 \dagger Electronic supplementary information (ESI) available: F-7000 instrumental parameters; Fig. S1 Rietveld refinement of the powder XRD pattern of Na₃Tb_{0.95}Eu_{0.5}(PO₄)₂; Fig. S2 Rietveld refinement of the powder XRD pattern of Na₃Tb_{0.3}Eu_{0.7}(PO₄)₂. See DOI: 10.1039/c6ra26164g

structure. They are built up on isolated REO, polyhedral and PO₄ tetrahedra.8 The presence of this particular structure suggests that the lattice can accommodate other cations with similar radii and charges without significant changes to the structural frame.9 Furthermore, this structure can weaken the concentration quenching effect and the critical concentration of activator ions is much higher than that of conventional inorganic phosphors. Therefore, the structure and optical properties of Na₃RE(PO₄)₂-related phosphors have been extensively studied. A great number of glaserite-type phosphors, such as $Na_3Y(PO_4)_2:Ce^{3+}, ^{10}Na_3La(PO_4)_2:Er^{3+}, ^{11}Na_3Gd(PO_4)_2:Ce^{3+}, ^{12}$ and $Na_3RE(PO_4)_2:Yb^{3+}$ (RE = Y, La, Gd)¹³ have been reported. Meanwhile, most of the phosphors are single-colored, and combining different phosphors is applied when a multicolor emission is needed. However, this combination suffers from the disadvantages of reabsorption among phosphors and different degradation rates.14 Therefore, great efforts have been devoted to develop single-host phosphors with a multicolor emission to meet the increasing demand of different illumination applications. In order to achieve color tunable emitting in single-phase hosts, several strategies are used, including controlling the temperature,15 band-gap modulation,16 crystal field adjustment,17 the combination of multiple rare ions with various color emissions,18 and codoping ion pairs based on the energy transfer mechanism. Codoping different rare earth ions as sensitizers and activators in a single matrix is one of the most

popular methods to control the emission color via energy transfer processes.19 Additional, tunable multicolor emission can be realized in phosphors under a single excitation wavelength. The multicolor tuning of phosphors has been achieved by co-doping RE³⁺ ion into suitable host lattice, such as Eu³⁺- Bi^{3+} , ²⁰ Tm^{3+} – Dy^{3+} (ref. 21) and Tb^{3+} – Eu^{3+} . ^{22–24}

It has been reported that Na₃La(PO₄)₂ crystallizes in the orthorhombic structure.8 Eu³⁺ and Tb³⁺ ions are frequently used as red and green activators in luminescent materials.19 However, the luminescence properties of Tb³⁺ and/or Eu³⁺ ions in Na₃La(PO₄)₂ host under near ultraviolet (NUV) light excitation have not been reported, and so far the energy transfer phenomenon from Tb3+ to Eu3+. In this contribution, Na3-La(PO₄)₂ was chosen as the host material. The structure, luminescence properties and chromaticity stability of Tb3+ and/or Eu³⁺ activated Na₃La(PO₄)₂ samples are studied in detail. The energy transfer process between Tb3+ and Eu3+ ions as well as the potential luminescence mechanism has been analyzed in Na₃La(PO₄)₂ host upon the excitation wavelength of 378 nm irradiation.

Experimental

Powder samples of $Na_3La_{1-x}(PO_4)_2:xEu^{3+}$ (x = 0-1.0), Na_3 - $La_{1-\nu}(PO_4)_2$: yTb^{3+} (y = 0-1.0), $Na_3La_{0.7-x}Tb_{0.3}(PO_4)_2$: xEu^{3+} (x = 0) 0-0.7), and $Na_3La_{0.95-y}Eu_{0.05}(PO_4)_2$:yTb³⁺ (y = 0-0.95) were prepared as follows. Stoichiometric amounts of analytical reagents NaNO₃, NH₄H₂PO₄, and 99.99% pure La₂O₃ were mixed. An appropriate amount of CO(NH2)2 was added as fuel. 99.99% pure Eu₂O₃ and Tb₄O₇ were dissolved in HNO₃ to convert into nitrate completely. These reagents were dissolved in water and then introduced into a muffle furnace maintained at 600 °C for 5 min. The obtained processor was subsequently ground in an agate mortar and then reacted at 900 °C for 4 h in air atmosphere. Finally, the products were gradually cooled to room temperature and reground for further measurements.

The phase purity of the products was checked by powder Xray diffraction (XRD) using a Bruker D8 X-ray diffractometer (Bruker Co. Ltd., Karlsruhe, Germany) with Cu K α radiation (λ = 1.5406 Å), operating at 40 kV and 40 mA. Structure refinements of XRD data were performed using the computer software General Structure Analysis System (GSAS) program.²⁵ The luminescence emission and excitation spectra of the samples were measured on a fluorescence spectrophotometer (F-7000, Hitachi, Japan) equipped with a 150 W Xe light source. The luminescence decay data were collected on an Edinburgh FLS920 combined fluorescence lifetime and steady state spectrometer with a 450 W xenon lamp and 60 µF flash lamp. For comparison, all measurements were conducted at room temperature with the identical instrumental parameters.

Results and discussion

Phase identification and crystal structure

The XRD patterns of Tb3+ and/or Eu3+ doped Na₃La(PO₄)₂ samples were measured at room temperature. Fig. 1 shows the powder XRD profiles of some representative samples. No

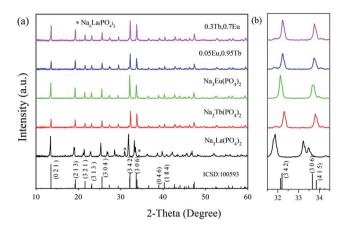

Fig. 1 Representative XRD patterns of $Na_3RE(PO_4)_2$ (RE = La, Tb, Eu) samples and ICSD no. 100593 (a); magnified XRD patterns in the region from 31.5 to 34.5 deg (b).

records of Na₃La(PO₄)₂, Na₃Tb(PO₄)₂ and Na₃Eu(PO₄)₂ are available in Joint Committee on Powder Diffraction Standards (ICPDS) or Inorganic Crystal Structure Database (ICSD). As shown in Table 1, the radius Nd3+ is quite close to that of La3+, Eu³⁺ and Tb³⁺. ²⁶ The compound Na₃Nd(PO₄)₂ is isostructural with $Na_3RE(PO_4)_2$ (RE = La, Eu and Tb). Therefore, the standard data of Na₃Nd(PO₄)₂ (ICSD no. 100593) serve as a certified reference.27 As presented in Fig. 1a, most of the samples are consistent with the standard file of Na₃Nd(PO₄)₂, indicating that the obtained samples are single phase and heavily doping Tb and/or Eu ions do not change the crystal structure. This is attributed to that Tb3+ or Eu3+ occupies La3+ sites for their similar radii and identical valence. However, as an exceptional case, two additional weak diffraction peaks at 30.95° and 34.27° ascribed to Na₆La(PO₄)₃ as a second phase can be discerned for the Na₃La(PO₄)₂ sample. A small shift of the XRD peaks of the $Na_3RE(PO_4)_2$ (RE = La, Eu, Tb) samples in comparison to the standard data of Na₃Nd(PO₄)₂ can be observed in Fig. 1b. The characteristic peak (3 4 2) shifts to the higher angle as the RE³⁺ sites are substituted by the $La^{3+} \rightarrow Nd^{3+} \rightarrow Eu^{3+} \rightarrow Tb^{3+}$ with the decrease of ionic radii. According to Bragg's diffraction equation, $2d \sin \theta = n\lambda$, in which n is an integer, λ is the X-ray wavelength, d is the spacing between the planes in the atomic lattice, and θ is the angle between the incident ray and the scattering planes. The substitution of the La3+ ions in the crystallographic structure by the smaller Tb3+ or Eu3+ ions reduces the cell dimensions of the crystal, leading to the increase of the 2θ value.

Table 1 The effective ionic radii of the different coordination sites of RE^{3+} in REO_v (RE = La, Nd, Eu, Tb; y = 6, 7, 8)

у	Ionic radius (Å)				
	La ³⁺	Nd ³⁺	Eu ³⁺	Tb ³⁺	
6	1.032	0.983	0.947	0.923	
7	1.10	_	1.01	0.98	
8	1.16	1.109	1.066	1.04	

Reported by Salmon et al., 27 Na₃Nd(PO₄)₂ crystallizes in Pbc2₁ (no. 29) space group and orthorhombic crystal system (ICSD no. 100593). As shown in Fig. 1, solid solutions of Na₃RE(PO₄)₂ (RE = La, Eu and/or Tb) may exist due the same valence and similar radii of these ions.28 Meanwhile, there are a lot of evidence about the iso-structural of orthorhombic Na₃Nd(PO₄)₂ with other sodium and rare-earth double orthophosphates Na₃- $RE(PO_4)_2$ (RE = Y, La-Er). Here the crystal structure data of Na₃Nd(PO₄)₂ is used as a starting model to refine the crystal structure. Fig. 2a and b exhibit the experimental, calculated and difference results from the Rietveld refinement of the two end components Na₃Tb(PO₄)₂ and Na₃Eu(PO₄)₂, respectively. All of the observed peaks can be indexed to the corresponding data. We can conclude that the desired single-phase phosphors with a glaserite-type structure have been synthesized and the patterns have not changed by doping Tb³⁺ and/or Eu³⁺ ions. No other phase or impurity can be detected, confirming the formation of a single phase. The low values of $R_{\rm wp}$, $R_{\rm p}$ and χ^2 shown in Table 2 indicate that the refined crystal structure data are reliable. Both Na₃Tb(PO₄)₂ and Na₃Eu(PO₄)₂ crystallize in the orthorhombic crystal system with space group Pbc21 and N = 24. Their unit cell parameters differ from that of $Na_3Nd(PO_4)_2$ $(a = 15.874 \text{ Å}, b = 13.952 \text{ Å}, c = 18.470 \text{ Å}, V = 4090.63 \text{ Å}^3),$ resulted from the substitution of Nd3+ by Tb3+ or Eu3+. The Rietveld analysis shows that the samples are in crystalline phase

and no phase mixture was observed. Rietveld plots of Na₃- $Tb_{0.95}Eu_{0.5}(PO_4)_2$ and $Na_3Tb_{0.3}Eu_{0.7}(PO_4)_2$ are presented in Fig. S1 and S2 (in the ESI†), respectively. All of the observed peaks satisfy the reflection conditions, confirming the formation of a single phase with no impurities. The remarkable good fit between the experimental data and calculated line confirm the phase purity of the as-prepared samples.

Fig. 3a depicts the crystal structure of the $Na_3RE(PO_4)_2$ (RE = La, Eu, Tb) unit cell viewed along a-direction from the parallel projection, the coordination environment of RE³⁺ sites, and the ideal glaserite structure. The Na₃RE(PO₄)₂ framework is made up of isolated PO₄ tetrahedron and $[REO_v]$ (y = 6, 7, 8) polyhedron that arranged in an ordered way which results in the tunnel. The basic structure units are helical ribbons [REO_v] formed by six corner sharing [PO₄] tetrahedron that alternate "up" and "down.". The pinwheels are linked through [PO₄] tetrahedra to form layers with alkali atoms located between the layers. Fig. 3b and c demonstrate the six kinds of RE sites in a unit cell along b-direction. The ribbons run along some

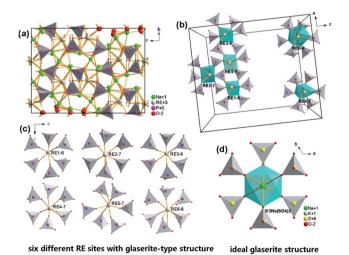

Fig. 3 Crystal structure of the $Na_3RE(PO_4)_2$ (RE = La, Eu, Tb) unit cell viewed along a-direction from the parallel projection (a); the coordination environment of different Nd3+ sites in a unit cell (b); the expansion particular six kinds of Nd3+ (c); the ideal glaserite structure of the $K_3Na(SO_4)_2$ (d).

directions of unit-cell with a period of four or eight tetrahedral. The coordination of the RE atoms is 6-folded for RE1 and RE3. 7-folded for RE2, RE4, RE5 and 8-folded for RE6. The variety in coordination numbers is due to a rotation of the certain [PO₄] tetrahedron around one of their edges. The REO₂ polyhedral are isolated because they do not share any O atom. In addition, the shortest RE-RE distances in Na₃Tb(PO₄)₂ and Na₃Eu(PO₄)₂ are about 4.641 and 4.646 Å (RE2-RE5), respectively, which is a long distance that energy migration of the doped rare earth ions is difficult, similar observation has also been witnessed in some systems such as $Na_3Gd_{1-x}Eu_x(PO_4)_2$ (ref. 31) and Na₃Gd(PO₄)₂:Ce³⁺.12

Luminescence properties of Tb³⁺ and/or Eu³⁺ doped Na₃La(PO₄)₂ phosphors

Fig. 4 illustrates the UV-vis excitation (PLE, $\lambda_{em} = 546$ nm) and emission (PL, $\lambda_{em} = 378$ nm) spectra of Na₃La_{1-x}(PO₄)₂:xTb³⁺ with x = 0.01-1.0. The PLE spectrum of Na₃Tb(PO₄)₂ involves several sharp lines in the 280-420 nm range. The sharp f-f excitation lines at about 302, 317, 340, 351, 358, 368, 378 and 486 nm are assigned to ${}^{7}F_{6} - {}^{5}H_{6}$, ${}^{7}F_{6} - {}^{5}H_{7}$, ${}^{7}F_{6} - {}^{5}G_{2}$, ${}^{7}F_{6} - {}^{5}D_{2}$, ${}^{7}F_{6} - {}^{5}L_{10}$, ${}^{7}F_{6} - {}^{5}G_{6}$ and ${}^{7}F_{6} - {}^{5}D_{4}$, respectively.³¹ Under 378 nm NUV excitation, the PL spectrum of Na₃La_{0.99}(PO₄)₂:0.01Tb³⁺ presents a group of ${}^5D_{3,4} \rightarrow {}^7F_I$ transitions: ${}^5D_3 \rightarrow {}^7F_5$ (415 nm), $^{5}D_{3} \rightarrow ^{7}F_{4}$ (437 nm), $^{5}D_{4} \rightarrow ^{7}F_{6}$ (490 nm), $^{5}D_{4} \rightarrow ^{7}F_{5}$ (546 nm), $^5\mathrm{D_4} \rightarrow {}^7\mathrm{F_4}$ (586 nm) and $^5\mathrm{D_4} \rightarrow {}^7\mathrm{F_3}$ (623 nm). With the increase of Tb³⁺ concentration (x), the blue emissions from the $^5D_3 \rightarrow$ ⁷F_{5,4} transitions are quenched gradually, while the green emissions from the ${}^5D_4 \rightarrow {}^7F_{6,5,4,3}$ transitions increase continuously. For the Tb³⁺ ion, the energy gap between the ⁵D₃ and ⁵D₄ levels is about 5915 cm⁻¹, which is quite close to that between $^{7}\mathrm{F}_{6}$ and $^{7}\mathrm{F}_{0}$ levels (6000 cm $^{-1}$). 32 Hence, if the Tb $^{3+}$ concentration (y) is high enough, the emission from the ⁵D₃ level of Tb³⁺ is much weaker than that from the ⁵D₄ level due to the cross relaxation via the resonant energy transfer process: Tb³⁺ (⁵D₃) + $Tb^{3+}(^{7}F_{6}) \rightarrow Tb^{3+}(^{5}D_{4}) + Tb^{3+}(^{7}F_{0})$ and the green emission of the ${}^5D_4 \rightarrow {}^7F_5$ (546 nm) becomes predominant.³³ The PL intensity of Tb^{3+ 5}D₄ \rightarrow ⁷F₅ transition increases gradually with

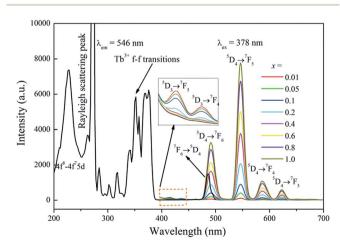

Fig. 4 The PLE spectrum of Na₃Tb(PO₄)₂ and the PL spectra of Na₃- $La_{1-x}(PO_4)_2:xTb^{3+}$ (x = 0.01–1.0) samples.

its concentration (x) increasing, and reaches a maximum at x =1. This result indicates that no concentration quenching exists in the Na₃La(PO₄)₂ host among the Tb³⁺ ions. The Na₃Tb(PO₄)₂ sample shows strong green emission under 378 nm NUV irradiation excitation, which makes it be a potential green phosphor for NUV LED application.

The PLE spectrum of Na₃Eu(PO₄)₂ and PL spectra of Na₃- $\text{La}_{1-\nu}(\text{PO}_4)_2$: νEu^{3+} ($\nu = 0.01$ –1.0) are shown in Fig. 5. The PLE spectrum consists of a weak broad band assigned to the chargetransfer transition (CTB) between Eu³⁺ and O²⁻, some narrow lines in the range of 230-320 nm (the strongest peak located at about 306 nm is due to Rayleigh scattering), and several sharp lines from 360-480 nm. These sharp lines correspond to the characteristic f → f transitions of Eu³⁺ ions within its 4f⁶ configuration. They are ascribed to ${}^{7}F_{0} \rightarrow {}^{5}D_{4}$ (360 nm), ${}^{7}F_{0} \rightarrow$ ${}^{5}\text{G}_{L}, {}^{5}\text{L}_{7} \text{ (381 nm)}, {}^{7}\text{F}_{0} \rightarrow {}^{5}\text{L}_{6} \text{ (394 nm)}, {}^{7}\text{F}_{0} \rightarrow {}^{5}\text{D}_{3} \text{ (414 nm)}, \text{ and}$ $^{7}\text{F}_{0} \rightarrow ^{5}\text{D}_{2}$ (464 nm) transitions of Eu³⁺ ion, respectively. Excitation into the ${}^{7}F_{0} \rightarrow {}^{5}L_{6}$ transition of Eu³⁺ at 394 nm yields some characteristic emission lines from the ⁵D_{0.1} excited states to the ${}^{7}\text{F}_{1}$ ground states, i.e., ${}^{5}\text{D}_{1} \rightarrow {}^{7}\text{F}_{1}$ (536 nm), ${}^{5}\text{D}_{1} \rightarrow {}^{7}\text{F}_{2}$ (556 nm), ${}^{5}D_{0} \rightarrow {}^{7}F_{1}$ (594 nm), ${}^{5}D_{0} \rightarrow {}^{7}F_{2}$ (620 nm), ${}^{5}D_{0} \rightarrow {}^{7}F_{3}$ (655 nm), and ${}^5D_0 \rightarrow {}^7F_4$ (703 nm), respectively. 4 However, the 5D_0 \rightarrow ⁷F₀ transition (about 580 nm) is very weak and can hardly be detected.

The two dominant bands at 594 (${}^{5}D_{0} \rightarrow {}^{7}F_{1}$ transition) and 620 nm (${}^{5}D_{0} \rightarrow {}^{7}F_{2}$ transition) confer on the sample an orangered luminescence upon excitation with 394 nm light. It is known that the magnetic-dipole transition ${}^5D_0 \rightarrow {}^7F_1$ is insensitive to the symmetry of the Eu3+ site, while the forced electric dipole transition ${}^5D_0 \rightarrow {}^7F_2$ is hypersensitive to the local environment.^{35,36} Therefore, the intensity ratio (R) of (${}^5D_0 \rightarrow$ $^{7}F_{2}$ /($^{5}D_{0} \rightarrow ^{7}F_{1}$) gives a measure of the Eu³⁺ site symmetry in the lattice. A higher value of R(R > 1) suggests that Eu³⁺ locates at the site without inversion symmetry. Otherwise, Eu³⁺ ion locates at the site with inversion symmetry, leading to a lower value of R(1 > R > 0).³⁷ As shown in Fig. 3d, Na⁺ has an inversion symmetric environment in the ideal glaserite structure of $K_3Na(SO_4)_2$. However, upon substitution of Na^+ sites by RE^{3+} ,

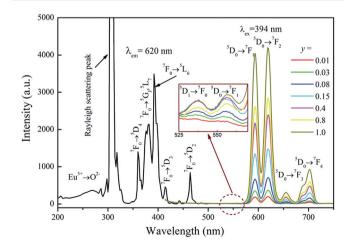

Fig. 5 The PLE spectrum of Na₃Eu(PO₄)₂ and the PL spectra of Na₃- $La_{1-y}(PO_4)_2: yEu^{3+}$ (y = 0-1) samples.

there will be some distortion in NaO₆ octahedron. The Na₃-RE(PO₄)₂ structure seems to be a distorted glaserite structure. In this structure six different types of REO_y polyhedral can be expected. Hence, the Eu³⁺ ion may occupy six sites in the Na₃-RE(PO₄)₂ lattice, as shown in Fig. 3b and c. Here, the intensity of $^5D_0 \rightarrow ^7F_1$ is comparable with that of $^5D_0 \rightarrow ^7F_2$. The value of R calculated is about 1.02, indicating that the Eu³⁺ ions occupies a symmetric and a non-symmetric site almost equally. This agrees with the results of Eu³⁺ doped $K_3Y(PO_4)_2$ (ref. 34) and Na₃Y(PO₄)₂ (ref. 38) but challenges the results of Eu³⁺ doped Rb₃Y₂(PO₄)₃ and Rb₃La(PO₄)₂.

The PL intensity (${}^5\mathrm{D}_0 \to {}^7\mathrm{F}_2$) of Na₃La_{1-y}(PO₄)₂:yEu³⁺ increases with increasing Eu³⁺ concentration (y) until a maximum intensity about y=1.0 is reached. These observations confirm that the concentration quenching of Eu³⁺ does not occur in Na₃La(PO₄)₂ host, so highly doping concentration samples are performed here.

It is worthy to be noted that both $Na_3La_{1-x}(PO_4)_2:xTb^{3+}$ and Na₃La_{1-y}(PO₄)₂:yEu³⁺ phosphors have a much high quenching concentration, actually the complete quenching would not occur even at x or y = 1.0, at which the La³⁺ sites are replaced by Tb³⁺ or Eu³⁺ completely. Taking into account the inherent structural feature of Na₃RE(PO₄)₂ host, in which the Tb³⁺ or Eu³⁺ ions occupy the RE³⁺ sites of polyhedral which isolate from each other by a large spatial distance and join by RE-O-P-O-RE. The large spatial distance between RE3+ ions and the shielding of PO₄ tetrahedrons hinders the long range energy transfer between Tb3+ or Eu3+ ions and consequently prevents the occurrence of concentration quenching. Therefore, the high concentration quenching was observed in Na₃La_{1-x}(PO₄)₂:xTb³⁺ and $Na_3La_{1-\nu}(PO_4)_2$:yEu³⁺ phosphors. The similar phenomenon was also reported by Chen et al. in $K_3R(PO_4)_2$: Tb^{3+} (R = Y and Gd) phosphors, 40 Ju et al. in Na₃Gd_{1-x}Eu_x(PO₄)₂ phosphors, 30 and Jiang et al. in K₃Gd(PO₄)₂:Tb³⁺,Eu³⁺ phosphor.⁴¹

In order to obtain multicolor tunable luminescence of the $Na_3La(PO_4)_2$ phosphor, Tb^{3+} and Eu^{3+} ions with different relative concentration into the $Na_3La(PO_4)_2$ host lattice were codoped in our work. The PLE and PL spectra of the

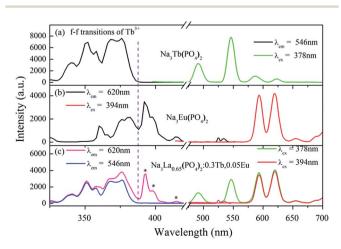

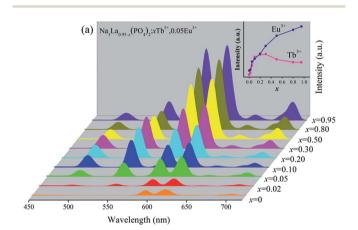

Fig. 6 PLE and PL spectra of Na₃Tb(PO₄)₂ (a), Na₃Eu(PO₄)₂ (b), and Na₃La_{0.65}(PO₄)₂:0.3Tb³⁺,0.05Eu³⁺ (c).

 $Na_3La_{0.65}(PO_4)_2:0.3Tb^{3+},0.05Eu^{3+}$ sample are shown in Fig. 6. For comparison, the PLE and PL spectra of Na₃Tb(PO₄)₂ and $Na_3Eu(PO_4)_2$ are also presented. The PLE spectrum (Fig. 6c) of the Na₃La_{0.65}(PO₄)₂:0.3Tb³⁺,0.05Eu³⁺ by monitoring the emission of Tb³⁺ at 546 nm is almost identical to that of Na₃Tb(PO₄)₂ (Fig. 6a) within the experimental error. The PLE band/line of Eu³⁺ is undetectable, implying that Eu³⁺ cannot transfer energy to Tb³⁺. The PLE spectrum recorded at the 620 nm of Eu³⁺ emission is dominated by Tb³⁺ bands/lines, which are similar to that of monitoring the Tb3+-emission, but shows large difference with that of Eu³⁺ (Fig. 6b). Only several f-f transition lines of Eu³⁺ are evidently observed (marked by stars in Fig. 6c). The presence of Tb³⁺-related PLE bands/lines in the PLE spectrum of Eu3+ emission clearly indicates the occurrence of energy transfer from Tb³⁺ to Eu³⁺. Upon 394 nm excitation (${}^{7}F_{0} \rightarrow {}^{5}L_{6}$ of Eu³⁺), only emission from Eu³⁺ is observed, and the positions of all emission peaks are identical to those in Fig. 6b of Na₃-Eu(PO₄)₂. Excited at 378 nm UV irradiation (${}^{7}F_{6} \rightarrow {}^{5}G_{6}$ of Tb ${}^{3+}$), the characteristic sharp emissions from both Eu³⁺ and Tb³⁺ can be detected, confirming that Tb3+ can partially transfer excitation energy to Eu³⁺ via its absorption of 4f state. Therefore, the relative intensities of these two emissions can be varied by adjusting the concentrations of the two activators through the principle of energy transfer.

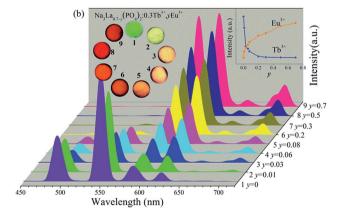

Fig. 7 PL spectra ($\lambda_{ex}=378$ nm) of Na₃La_{0.95-x}(PO₄)₂:xTb³⁺,0.05Eu³⁺ (x=0–0.95, a) and Na₃La_{0.7-y}(PO₄)₂:0.3Tb³⁺,yEu³⁺ (y=0–0.7, b) phosphors together with their digital photographs under a 365 nm UV lamp.

Paper

Fig. 7 illustrates the variations of PL spectra and corresponding intensities of Na₃La_{0.95-x}(PO₄)₂:xTb³⁺,0.05Eu³⁺ and $Na_3La_{0.7-\nu}(PO_4)_2$: 0.3Tb³⁺,yEu³⁺ phosphors. The emission profile of all the Tb³⁺/Eu³⁺ codoped samples contain the characteristic sharp emission peaks of both Tb³⁺ and Eu³⁺ under excitation at 378 nm. The increasing concentrations of the Eu³⁺ or Tb³⁺ ions bring no obvious alteration in the intensity ratio of $(^5D_0 \rightarrow ^7F_2)$ / $(^{5}D_{0} \rightarrow {}^{7}F_{1})$, indicating that the degree of the local symmetry around Eu³⁺ ions keeps constant. As shown in Fig. 7a, the PL intensities of Eu3+ at 620 nm increase systematically with increasing the Tb^{3+} concentration (x), because the increase of Tb³⁺ concentration results in more sensitizers transferring the energy to Eu³⁺ ions. Meanwhile, the Tb³⁺ green emission intensity reaches its maximum at x = 0.3, and then decreases due to the concentration quenching effect with further increasing the Tb^{3+} concentration (x). The inset of Fig. 7a depicts the dependences of the PL intensities ($(^5D_4 \rightarrow ^7F_5)$ transition of Tb³⁺; $^5D_0 \rightarrow ^7F_2$ transition of Eu³⁺; $\lambda_{ex} = 378$ nm)) on the Tb³⁺ concentration (y). The Eu³⁺ PL intensity is enhanced about 11 times by codoping with Tb3+. In Fig. 7b, the PL intensity of Tb3+ decreases monotonously with the increase of Eu^{3+} concentration from y = 0 to 0.7, while the Eu^{3+} PL intensity increases to a maximum at y = 0.7. This observation indicates that the energy transfer from ${
m Tb}^{3+}$ to ${
m Eu}^{3+}$ ions can occur in

current excitation condition in Tb³⁺/Eu³⁺ codoped Na₃La(PO₄)₂

phosphor. Therefore, the relative intensities of these two

emissions can be varied by adjusting the concentrations of the two activators through the principle of energy transfer to realize

the tunable emission color. The digital emission color photos

were depicted in the inset of Fig. 7b, clearly indicating that the

emission color can be tuned from green to reddish orange with

Decay curves and energy transfer mechanism

increasing the Eu³⁺ concentration (y).

It has been witnessed that an efficient energy transfer from Tb $^{3+}$ to Eu $^{3+}$ occurs in Na $_3$ La(PO $_4$) $_2$ host. In order to further investigate the energy transfer between Tb $^{3+}$ and Eu $^{3+}$ in Na $_3$ La(PO $_4$) $_2$, luminescent decay curves of Tb $^{3+}$ emission and Eu $^{3+}$ emission in Na $_3$ La $_{0.7-y}$ (PO $_4$) $_2$:0.3Tb $^{3+}$,yEu $^{3+}$ (y = 0–0.7) samples have been measured. The decay curves monitored at 546 nm (Tb $^{3+}$ 5 D $_4$ \rightarrow 7 F $_5$ transition) and 620 nm (Eu $^{3+}$ 5 D $_0$ \rightarrow 7 F $_5$ transition) with excitation of 378 nm irradiation are presented in Fig. 8a and b, respectively.

It is found that the decay curves of Tb³⁺ emission cannot be fitted in terms of a single-exponential function, but can be well fitted by a double-exponential function:

$$I = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2)$$
 (1)

where I is the luminous intensity at time t; A_1 and A_2 are the fitting parameters; and τ_1 and τ_2 are rapid and slow lifetimes for exponential components, respectively. The decay process of these samples is characterized by an effective lifetime τ , which can be calculated using eqn (2) as follows

$$\tau = (A_1 \tau_1^2 + A_2 \tau_2^2) / (A_1 \tau_1 + A_2 \tau_2) \tag{2}$$

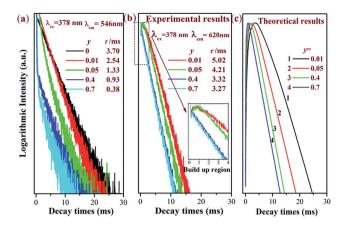

Fig. 8 Luminescence decay curves of Tb³⁺ 546 nm emission ($^5D_4 \rightarrow ^7F_5$) (a), Eu³⁺ 620 nm emission ($^5D_0 \rightarrow ^7F_5$) (b) and the corresponding simulation curves (c).

The values of τ_{Tb} are calculated to be 3.70, 2.54, 1.33, 0.93 and 0.38 ms for Na₃La_{0.7-y}(PO₄)₂:0.3Tb³⁺,yEu³⁺ phosphors with $y=0,\ 0.01,\ 0.05,\ 0.4$ and 0.7. As shown in Fig. 9, the effective lifetime of Tb³⁺ ions decreases with the increase of Eu³⁺ due to the ET_{Tb \rightarrow Eu} process.

For the ET_{Tb→Eu} process, the transfer probability ($P_{\text{Tb→Eu}}$) can be expressed by eqn (3)⁴²

$$P_{\text{Tb}\to\text{Eu}} = 1/\tau - 1/\tau_0 \tag{3}$$

where $P_{\mathrm{Tb}\to\mathrm{Eu}}$ is the energy transfer probability and τ and τ_0 are the lifetimes for Tb^{3+} with and without the Eu^{3+} ions, respectively. In addition, the energy transfer efficiency $(\eta_{\mathrm{Tb}\to\mathrm{Eu}})$ can be evaluated using eqn (4),

$$\eta_{\mathrm{Tb}\to\mathrm{Eu}} = 1 - \tau/\tau_0 \tag{4}$$

The values of $P_{\mathrm{Tb} \to \mathrm{Eu}}$ and $\eta_{\mathrm{Tb} \to \mathrm{Eu}}$ are calculated and are also shown in Fig. 9. Both the values of $P_{\mathrm{Tb} \to \mathrm{Eu}}$ and $\eta_{\mathrm{Tb} \to \mathrm{Eu}}$ increase obviously with increasing the Eu^{3^+} concentration (y), indicating that the energy-transfer process become more efficient with high Eu^{3^+} ion concentration.

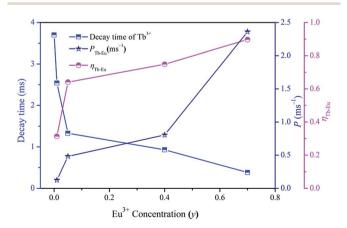

Fig. 9 Dependence of Tb³⁺ decay time, $P_{\text{Tb} \to \text{Eu}}$ and $\eta_{\text{Tb} \to \text{Eu}}$ on Eu³⁺ concentration (y) in Na₃La_{0.7-y}(PO₄)₂:0.3Tb³⁺,yEu³⁺.

Fig. 8b illustrates the decay curves of Eu³⁺ emission. All the decay curves of Eu³⁺ emission could be well fitted into singly exponential equation

$$I_t = I_0 \exp(-t/\tau) \tag{5}$$

where I_0 and I_t are for the intensities of Eu³⁺ emission at time t_0 and t, respectively; τ denotes the lifetimes for Eu³⁺. The calculated values of τ_{Eu} are 5.02, 4.21, 3.32 and 3.27 ms for y = 0.01, 0.05, 0.4 and 0.7 in Na₃La_{0.7- ν}(PO₄)₂:0.3Tb³⁺,yEu³⁺ phosphors.

It is obvious that the Eu³⁺ decay curves recorded at the $^5D_0 \rightarrow$ ⁷F₅ transition (620 nm) exhibit a rising step. The fluorescence intensity increases with increasing time, then reaching a maximum, and finally decreases until the decay process completes. Therefore, there are two different processes for the emission of Eu³⁺: decay process and build-up process. In the initial build-up process, the energy absorbed by the ${}^{7}F_{6} \rightarrow {}^{5}G_{6}$ transition of Tb³⁺ ions is transferred to Eu³⁺ ions. This process is significantly influenced by the Eu³⁺ concentration. As shown in Fig. 8b, with increasing the Eu³⁺ concentration (y), the initial build-up process becomes faster and faster, suggesting that the ET_{Tb→Eu} process becomes more efficient with higher Eu³⁺ concentration.⁴³ When the $Na_3La_{0.7-\nu}(PO_4)_2:0.3Tb^{3+}$, νEu^{3+} samples are excited by 378 nm irradiation, the rate equations for the population densities in the ⁵D₄ level of Tb³⁺ and the ⁵D₀ of Eu3+ ion can be expressed as follows,44

$$dN_{Tb}/dt = -N_{Tb}/\tau_{Tb} - K_{Tb-Eu}N_{Tb}$$
 (6)

$$dN_{\rm Eu}/dt = -N_{\rm Eu}/\tau_{\rm Eu} + K_{\rm Tb-Eu}N_{\rm Tb}$$
 (7)

where the $N_{\rm Tb}$ and $N_{\rm Eu}$ are the population intensities of the $^5{\rm D}_4$ level of Tb³⁺ and the 5D_0 of Eu³⁺, respectively. $K_{\text{Tb-Eu}}$ is the nonradiative energy transfer rate from the ⁵D₄ state of Tb³⁺ to ⁵D₀ of Eu^{3+} . Then the fluorescence intensity I(t) of Eu^{3+} ions at 620 nm excited at 378 nm irradiation can be given as following equation:

$$I(t) = N_{\text{Eu}}(t) = N_{\text{Eu}}/\tau_{\text{Eu}}$$

$$= \frac{K_{\text{Tb-Eu}}N_{\text{Tb}}}{1/\tau_{\text{Eu}} - 1/\tau_{\text{Tb}}} \left[\exp\left(-\frac{t}{\tau_{\text{Tb}}}\right) - \exp\left(-\frac{t}{\tau_{\text{Eu}}}\right) \right]$$
(8)

Using the measured values of τ_{Tb} and τ_{Eu} , the simulation curves for Na₃La_{0.7-y}(PO₄)₂:0.3Tb³⁺,yEu³⁺ samples are obtained as presented in Fig. 8c, which show two process for Eu³⁺ emission, being similar to the measured curves. That is to say, the theoretical results are consistent with the experimental observations.

In general, the energy transfer between the sensitizer and activator may take place via exchange interaction and multipolar interaction. The energy transfer mechanism can be determined using the following relationship:45

$$ln(I_0/I) \propto C \text{ and } I_{S0}/I_S \propto C^{\alpha/3}$$
 (9)

in which I_{S0} and I_{S} are the luminescence intensities of Tb³⁺ in the absence and presence of Eu^{3+} , respectively; C is the total

concentration of Tb³⁺ and Eu³⁺; $\ln(I_{S0}/I_S) \propto C$ is corresponding to the exchange interaction; $\alpha = 6$, 8, and 10 are dipole-dipole, dipole-quadrupole, and quadrupole-quadrupole interactions. The relationships are illustrated in Fig. 10a-d, respectively for $Na_3La_{0.7-\nu}(PO_4)_2:0.3Tb^{3+}$, yEu^{3+} phosphors. The linear behavior was observed only when $\alpha = 6$, indicating that energy transfer from Tb^{3+} to Eu^{3+} in $Na_3La(PO_4)_2$ host occurs *via* a dipole-dipole interaction.

The scheme of energy transfer from Tb³⁺ to Eu³⁺ in Na₃-La(PO₄)₂ host is demonstrated in Fig. 11. Tb³⁺ ions absorb the energy from 378 nm irradiation and are excited from the ground state of $({}^{7}F_{6})$ to the excited states of ${}^{5}D_{I}(J=2,3,4)$. Some of the excited Tb³⁺ radiative transmit from ⁵D₃ to the ground state ⁷F₆ directly with relatively weaker blue light emission of 415 and 437 nm, and other excited Tb³⁺ relax to the lowest excited state ⁵D₄ through non-radiative transition, then radiative decay to the ground state $(^{7}F_{6})$ with a strong green emission. When Eu³⁺ ions are codoped, part of the energy from ⁵D₄ to ⁷F₁ transition of Tb³⁺ will be transferred to Eu³⁺ through cross-relaxation due the obvious overlap between the ${}^5\mathrm{D}_4 \rightarrow {}^7\mathrm{F}_J$ emission of Tb^{3+} and $^{7}F_{0.1} \rightarrow ^{5}D_{0.1.2}$ absorption of Eu³⁺, then relax to the ground state $^{5}D_{0}$ of Eu³⁺ and finally radiative decay to the ground state ($^{7}F_{0}$) with an reddish orange emission.44

CIE chromaticity coordinates of Na₃La(PO₄)₂:Tb³⁺,Eu³⁺

The CIE chromaticity coordinates (X, Y) for Na₃La_{0.7- ν}(- PO_4 ₂:0.3Tb³⁺,yEu³⁺ (y = 0-0.7) samples were calculated in the case of 378 nm excitation and the results are shown in Fig. 12. The chromaticity coordinates of Na₃Eu(PO₄)₂ phosphor is also presented. The CIE chromaticity coordinates (X, Y) changes from point 1 (0.2987, 0.5695) to point 7 (0.6203, 0.3505) with the increase of Eu³⁺ concentration (y). The as formed Na₃La_{0.95-x}(- PO_4 ₂: xTb^{3+} ,0.05Eu³⁺ (x = 0-0.95) phosphors show typical reddish-orange luminescence. However, their CIE coordinates are too close to be distinguished from each other in a chromaticity diagram with the changes of the Tb³⁺ ion concentration, so they are not presented.

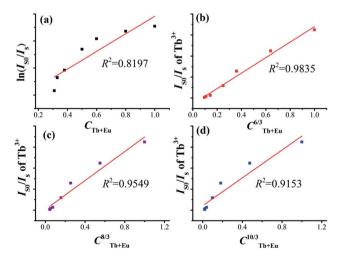

Fig. 10 Dependence of $\ln(I_{SO}/I_S)$ on C_{Tb+Eu} (a) and the dependence of I_{SO}/I_S on $C_{Tb+Eu}^{6/3}$ (b), $C_{Tb+Eu}^{8/3}$ (c) and $C_{Tb+Eu}^{10/3}$ (d).

Paper RSC Advances

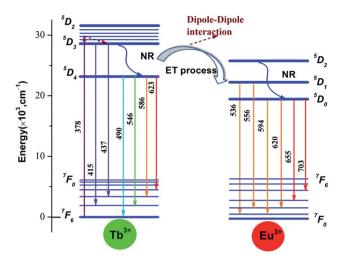

Fig. 11 Scheme of energy transfer from Tb^{3+} to Eu^{3+} in $Na_3La(PO_4)_2$ host.

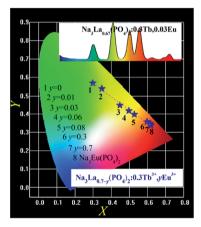

Fig. 12 CIE chromaticity diagram of the selected Na₃La_{0.7-y}(-PO₄)₂:0.3Tb³⁺,yEu³⁺ (y=0-0.7) and Na₃Eu(PO₄)₂ phosphors under 378 nm UV irradiation excitation. The inset shows the PL spectrum of Na₃La_{0.67}(PO₄)₂:0.3Tb³⁺,0.03Eu³⁺ under 378 nm UV irradiation excitation.

The PL spectrum of Na₃La_{0.67}(PO₄)₂:0.3Tb³⁺,0.03Eu³⁺ phosphor shown as inset in Fig. 12 exhibits a green emission of the Tb³⁺ and the red emission of the Eu³⁺ ions. These emission lines of Tb3+ and Eu3+ cover the whole visible light region with tunable intensity, resulting in a color-tunable emission. Therefore, it can be expected to achieve color-tunable emission by regulating spectral composition induced by the energy transfer between Tb3+ and Eu3+ ions in the Na₃La(PO₄)₂ host under NUV irradiation excitation. According to Grassman's Laws of additive color mixture, 46,47 the emission color of Na₃-La(PO₄)₂:Tb³⁺,Eu³⁺ can be matched by a linear combination of the emission color of Na₃La(PO₄)₂:Tb³⁺ and that of Na₃- $La(PO_4)_2$:Eu³⁺. It is obvious that the coordinate Y changes linearly with the coordinate X as shown in Fig. 12. Plotting y vs. x, a straight line is obtained. The values of intercept, slope, and linear regression coefficient are 0.7782, -0.7037, and 0.9902 respectively. The expression is shown as below:

$$Y = 0.7782 - 0.7037X \tag{10}$$

The above equation should mathematically demonstrate the range of chromaticity coordinates that we can obtain by adjusting the Tb³+ and Eu³+ concentrations. It is obvious that the chromaticity coordinates for the Na₃La(PO₄)₂:Tb³+,Eu³+ phosphor falls on a line connecting the two chromaticity coordinates of Na₃La(PO₄)₂:Tb³+ and Na₃La(PO₄)₂:Eu³+, respectively. With increasing the Eu³+ concentration (y), the chromaticity coordinate for Na₃La_{0.7-y}(PO₄)₂:0.3Tb³+,yEu³+ phosphors move from the chromaticity point 1 of Na₃La_{0.7}(PO₄)₂:0.3Tb³+ toward point 8 of Na₃Eu(PO₄)₂ along this straight line. The prepared Na₃La(PO₄)₂:Tb³+,Eu³+ phosphor exhibits efficient tunable emission in the visible-light region upon excitation with NUV irradiation, and might find potential applications in multicolor displays and other optoelectronic devices.

Conclusions

In a conclusion, a series of Tb³⁺ and/or Eu³⁺ doped Na₃La(PO₄)₂ phosphors have been successfully synthesized and their luminescence properties have been investigated in detail. The glaserite-like orthorhombic structure provides the Na₃La(PO₄)₂ host the possibility of doping with Tb3+ or Eu3+ ions without substantial luminescence quenching. Tb³⁺ can efficiently sensitize Eu³⁺ emission under NUV excitation. The energy transfer mechanism (Tb³⁺ \rightarrow Eu³⁺) was demonstrated to be dominated by a dipole-dipole interaction. The luminescence decay properties of Eu³⁺ in Na₃La(PO₄)₂:Tb³⁺,Eu³⁺ samples under ${}^{7}F_{6}{}^{-5}G_{6}$ excitation (378 nm) within 7 ions were simulated with the energy transfer theory. The emission color of $Na_3La_{0.7-y}(PO_4)_2:0.3Tb^{3+}$, yEu^{3+} phosphors can be tunable from green through yellow and red region by adjusting the Eu³⁺ concentration. These results indicate that the as-synthesized phosphors may find potential applications as a color-tunable emitting material in solid state lighting.
