1. Introduction

Methane $(CH₄)$, the second potent greenhouse gas, is often found in environment, industrial and domestic areas.¹⁻³ It is the major component of natural gas, which is used widely in industries, automobiles and homes. However, it is necessary to detect CH4 from coal mines, factories, farmland ventilation or natural gas-fueled appliances because it can form an explosive mixture in air if its concentration is in the range of 5–15%. There are several traditional techniques for $CH₄$ detection, such as gas chromatography equipped with a flame ionization detector (GC-FID)4,5 or infrared spectral radiometry.⁶ However, these common measurement methods for $CH₄$ have some disadvantages, requiring high cost equipment and strict working conditions. In the past few decades, metal-oxide semiconductors, such as SnO $_2$, 2 α -Fe $_2$ O $_3$, 7 and ZnO, 8 have been investigated widely as CH $_4$ sensing materials because of their high response and simplicity in synthesis. Although these metal-oxide semiconductors have more advantages for CH₄ detection, there are also some problems including their low selectivity, particularly high working temperature (about 400-500 °C). The identification of CH₄ at temperatures lower than 350 \degree C is relatively difficult owing to its high thermodynamic stability compared to that of other

Room temperature methane sensing properties of α -Fe_{2-x}Cu_xO₃ nanoparticles

 α -Fe_{2-x}Cu_xO₃ (0 \leq x \leq 0.17) nanoparticles were synthesized using an improved homogenous coprecipitation method. The effects of doped Cu on crystal structure of α -Fe₂O₃ were investigated by field emission transmission electron microscopy, X-ray diffraction and Raman spectroscopy. Owing to the substitution of Cu²⁺ at the Fe³⁺ sites, the lattice parameters of α -Fe_{2-x}Cu_xO₃ with an average particle size of ~40 nm and a single corundum structure increased with increasing doped Cu concentration. The shifting of Raman peaks for α -Fe_{2-x}Cu_xO₃ to higher wavenumber was also observed due to the strong electron–phonon interactions and structural distortion after doping Cu. According to the conductivity measurements, doping Cu can increase the concentration of hole carriers and enhance the conductivity of the p-type α -Fe₂O₃ semiconductor. Furthermore, CH₄ sensing characterization showed that the α - $Fe_{2-x}Cu_xO₃$ nanoparticles are sensitive and have a good selectivity to CH₄ at room temperature, and the response of the material is evidently improved by doping with Cu. The maximum response to 2000 ppm CH₄ at room temperature and 50% relative humidity was obtained when $x \approx 0.10$, meeting the common requirements in application. These results suggest that α -Fe_{2-x}Cu_xO₃ nanoparticles can be considered a potential candidate for methane detection at room temperature. PAPER

hydrocarbons.³ High working temperature in an atmosphere containing CH4 is dangerous and may result in an explosion. Hence, there is strong demand for a reliable sensor that can detect CH₄ at or near room temperature. Nowadays, much effort has been devoted to reduce the gas-sensing temperature of metal oxides. For example, materials, such as Pd and Pt, catalyzing CH4 decomposition at a relatively low temperature of 300 $^{\circ}$ C are loaded mainly in the stable metal oxides.^{2,9} Unfortunately, the loading of noble metals has high cost and causes environmental pollution. Recently, great emphasis is being given on nanostructured^{4,10} and doped metal¹¹ oxides as sensor materials to reduce the gas-sensing temperature. Nevertheless, the operating temperature of the vast majority of $CH₄$ sensors is not room temperature, and further studies are still necessary.

As a result, in the present study, α -Fe_{2-x}Cu_xO₃ nanoparticles were selected and synthesized by an improved homogenous coprecipitation method. Based on the characteristics for the morphology, crystal structure and electric conductivity, the effects of doped Cu on crystal structure distortion and semiconducting property were investigated. The $CH₄$ sensing properties of the α -Fe_{2-x}Cu_xO₃ nanoparticles were then examined. As expected, the sensor using α -Fe_{2-x}Cu_xO₃ nanoparticles as a gas sensing material exhibited a receivable response to $CH₄$ at room temperature.

2. Experimental

All the chemical reagents were analytically pure without further purification. α -Fe_{2-x}Cu_xO₃ nanoparticles were prepared by an

Table 1 Mol ratio of n (Cu²⁺)/ n (Fe³⁺) for preparing the hydroxide of α - $Fe_{2-x}Cu_{x}O_{\overline{3}}$ nanoparticles

n (Cu ²⁺)/ Value Sample $n(Fe^{3+})$ of x
$CF-5$ 0.05 0.10
$CF-6$ 0.06 0.11
$CF-7$ 0.07 0.13
$CF-8$ 0.08 0.15
$CF-9$ 0.09 0.17

improved homogenous co-precipitation method. First, $FeCl₃·6H₂O$ and $CuCl₂·2H₂O$ were mixed and dissolved with different mol ratios of $n(Cu^{2+})/n(Fe^{3+})$ at a given constant Fe³⁺ concentration of 0.10 mol L^{-1} (shown in Table 1), which was marked as solution A. Ammonia was diluted five times with distilled water according to the volume ratio, marked as solution B. Solutions A and B were dropped slowly into a distilled water reaction medium, in which sodium stearate was used as the dispersing agent. During the reaction, the reaction medium was stirred by a magnetic stirring apparatus at 20 \degree C, and the dropping speeds of solutions A and B were controlled at a certain ratio to maintain the pH value of the entire system at about 3. The formed precipitates were centrifugally separated, washed, heated at 60 \degree C for 10 h, and then annealed at 300 °C in an oxygen atmosphere for 1 h.

Subsequently, α -Fe_{2-x}Cu_xO₃ gas sensors were fabricated as follows. The prepared α -Fe_{2-x}Cu_xO₃ nanoparticles were mixed with the solution of polyvinyl alcohol to form a paste, which was coated onto the α -Al₂O₃ ceramic sheets (22 mm in length, 4 mm in width, attached with a pair of Ag electrodes and shown as Fig. 1a) using a small brush to form a film with a thickness of around 0.5 mm.

The morphology and crystallization of the α -Fe_{2-x}Cu_xO₃ nanoparticles were observed using a FEI Tecnai G2 F20 field emission transmission electron microscope (TEM) with an acceleration voltage of 200 kV. The structural characterization was performed using a PANalytical X' Pert PRO X-ray diffractometer (XRD) with Cu K_{α 1} radiation ($\lambda = 0.15406$ nm). The vibrational modes and structural distortion of the α -Fe_{2-x}Cu_xO₃ nanoparticles were investigated using a Renishaw inVia confocal microprobe Raman spectroscopy with the laser excitation of 785 nm, which provided a power at the sample surface of \sim 1.7 mW and was focused through the 50 \times objective to a 1–2 mm spot, at room temperature. The electrical property of the

 α -Fe_{2-x}Cu_xO₃ gas sensors was measured using a two probe technique. The gas sensing experiments were carried out using a static testing method.¹² The schematic of the equipment for sensor resistance measurement is shown in Fig. 1b. The response of the sensor was determined by the resistance ratio of sensor device in clean air (R_a) and in an atmosphere containing test gas (R_g) , *i.e.*, the sensor response $S = R_a/R_g$. The value of R_a and R_g can be obtained by measuring the voltage on the load resistance $R_{\rm L}$.

3. Results and discussion

3.1. Morphological characteristics of the α -Fe_{2-x}Cu_xO₃ nanoparticles nanoparticles

Fig. 2 presents FE-TEM images of α -Fe_{2-x}Cu_xO₃ nanoparticles. Part (a) and (b) show the bright field TEM image and high resolution TEM (HRTEM) image of undoped α -Fe₂O₃ grains, whereas parts (c) and (d) provide the bright field TEM image and HRTEM image of α -Fe_{1.92}Cu_{0.08}O₃, respectively. Fig. 2a shows that the undoped α -Fe₂O₃ powder consists of irregular particles with sizes in the range from 20 to 80 nm. To obtain more detailed structural information, a corresponding HRTEM image was recorded on the edge of the nanoparticle, shown in Fig. 2b. From the magnified HRTEM image of the selected area (inset of Fig. 2b), the lattice fringes could be observed clearly and the lattice spacing was 0.362 nm, corresponding to the (012) plane of α -Fe₂O₃. In comparison, the Cu doped α -Fe₂O₃ $(\alpha$ -Fe_{1.92}Cu_{0.08}O₃) particles with a mean particle size of \sim 40 nm showed monodispersity (see Fig. 2c). The corresponding HRTEM image (Fig. 2d) displays the (104) plane with the d spacing of 0.266 nm for α -Fe_{1.92}Cu_{0.08}O₃. However, the d spacing did not increase significantly as expected, comparing with the value of undoped α -Fe₂O₃. TEM analysis of α -Fe_{2-x}- $Cu_xO₃$ nanoparticles is comparable to that of the Cu-doped α -Fe₂O₃ cubes reported in Sun's study.¹¹ Paper

3.2. Structural characteristics of the α -Fe_{2-x}Cu_xO₃ nanoparticles

The XRD patterns of the α -Fe_{2-x}Cu_xO₃ nanoparticles are shown in Fig. 3a. For undoped α -Fe₂O₃, all the diffraction peaks can be indexed by a single phase with the rhombohedral crystal structure of α -Fe₂O₃, which is consistent with the standard data file (PDF # 033-0664). For the α -Fe_{2-x}Cu_xO₃ (0 < x ≤ 0.17)

Fig. 1 Schematic of (a) α -Fe_{2-x}Cu_xO₃ gas sensors and (b) equipment for the sensor response measurements.

Fig. 2 TEM images of α -Fe_{2-x}Cu_xO₃ nanoparticles: (a) bright field TEM image and (b) HRTEM image showing grain with the (012) plane of undoped α -Fe₂O₃, (c) bright field TEM image and (d) HRTEM image showing grains with the (104) plane of α -Fe_{1.92}Cu_{0.08}O₃.

Fig. 3 (a) XRD patterns, (b) zoomed-in (104) and (110) peaks, and (c) room-temperature lattice parameters of α -Fe_{2-x}Cu_xO₃ nanoparticles.

nanoparticles, all diffraction peaks can also be successfully indexed to rhombohedral hematite and no other evident trace of impurity phase particularly copper oxide is detected. This indicates that the added Cu could be doped into the crystal structure of α -Fe₂O₃, retaining the rhombohedral structure of hematite. Furthermore, from the zoomed-in (104) and (110) diffraction peaks of the α -Fe_{2-x}Cu_xO₃ nanoparticles, as seen in Fig. 3b, the diffraction peaks all shifted to lower 2θ angles compared to those of undoped α -Fe₂O₃, and the offset of peaks increased with increasing doped Cu concentration. To investigate the effects of doped Cu on the crystal structure of α -Fe₂O₃, the room-temperature lattice parameters of α -Fe_{2-x}Cu_xO₃ nanoparticles were obtained by the software X'Pert HighScore Plus based on the XRD data, as depicted in Fig. 3c. The results show that the lattice parameters a, b and $c,$ all increased with increasing doped Cu concentration. The ionic radii (sixcoordination in a rhombohedral structure) of Fe^{3+} and Cu^{2+} are similar at 0.0645 nm and 0.073 nm,¹³ respectively. Therefore, Cu²⁺ can be doped into the crystal structure of α -Fe₂O₃ and partly substitute Fe^{3+} . There is no doubt that the lattice parameters may increase when the substitutions exist. Hence, the shift of diffraction peaks and increase in lattice parameters are in association with the substitutions of Fe^{3+} by Cu^{2+} . In addition, with increasing doped Cu concentration (x) , the lattice parameters of α -Fe_{2-x}Cu_xO₃ increased gradually, which was accompanied by the shift of the diffraction peaks to lower 2θ angles. Operation is a constrained on the subsequent of the common and the intermediation and the common and the subsequent of the subseque

In addition, to further investigate the structural distortion of Cu-doped α -Fe₂O₃ nanoparticles, the Raman spectra of the α - $Fe_{2-x}Cu_xO_3$ nanoparticles at room temperature were collected (see Fig. 4). The Raman peaks located at 222 cm^{-1} and 493 cm^{-1} correspond to A_{1g} modes, whereas the peaks at 241 cm^{-1} , 289 cm^{-1} , 405 cm^{-1} , and 606 cm^{-1} are assigned to E_{g} modes. This confirms the corundum structure of α -Fe_{2-x}Cu_xO₃ (0 \leq x \leq 0.17), which is consistent with the values reported in the literature.14,15 In general, substitutions of larger ions at the Fe sites may lead to an increase in the mean Fe–O bond length, resulting in a shift of the Raman peaks to lower wavenumbers. However, in the present study, it is puzzling that all of the Raman peaks of Cu doped α -Fe₂O₃ shifted slightly to higher wavenumbers, compared to those of undoped α -Fe₂O₃. According to Yogi and Varshney, similar Raman spectrum changes were also observed and attributed to the strong electron–phonon interactions and structural distortion in this system after doping Cu, accompanied with an increase in chemical bond strength.¹⁴ These structural changes of the α -Fe_{2-x}Cu_xO₃ nanoparticles induced by doped Cu are expected to have an effect on the electrical and $CH₄$ sensing properties.

3.3. Electrical properties of the α -Fe_{2-x}Cu_xO₃ gas sensors

Fig. 5 shows the conductivities of the α -Fe_{2-x}Cu_xO₃ gas sensors at room temperature. The conductivities of the sensors were calculated using eqn (1):

$$
\sigma = \frac{1}{\rho} = \frac{L}{RS} \tag{1}
$$

Fig. 4 Raman spectra of α -Fe_{2-x}Cu_xO₃ nanoparticles at room temperature.

where σ is the conductivity, ρ is the resistivity, L is the distance of the Ag electrodes, R is the resistance of α -Fe_{2-x}Cu_xO₃ gas sensor and S is the cross-sectional area of α -Fe_{2-x}Cu_xO₃ layer. As shown in Fig. 5, the conductivity of the α -Fe_{2-x}Cu_xO₃ gas sensor increased from 1.2×10^{-5} to 6.3×10^{-5} S m⁻¹ with increasing x in α -Fe_{2-x}Cu_xO₃ from 0 to 0.17. Clearly, Cu doping enhances the electric conduction capability of α -Fe₂O₃ gas sensor greatly.

According to Long's research,¹⁶ α -Fe₂O₃ annealed in air is an n-type semiconductor and the one annealed in oxygen usually a p-type semiconductor because a large amount of metallic ionic vacancies (point defects) will be formed if annealed in an oxygen atmosphere. These metallic ionic vacancies can accept electrons, and the holes are the majority carriers in α -Fe₂O₃ semiconductor material. For Cu doped α -Fe₂O₃, when a part of $Fe³⁺$ sites are occupied by Cu²⁺, holes with a +1 charge are formed simultaneously. This will no doubt increase the concentration of hole carriers and enhance the conductivity of the p-type α -Fe₂O₃ semiconductor. On the other hand, acceptor

Fig. 5 Conductivities of α -Fe_{2-x}Cu_xO₃ gas sensors at room temperature.

energy level (usually called isolated energy level) can be introduced between the valence band and conduction band if the substitutions of Cu^{2+} ions occur at the Fe sites. The acceptor impurities on the acceptor energy level will ionize and lead to an increase in conductive holes in the valence band. As a result, the conduction capability of the $Fe₂O₃$ semiconductor is enhanced, and the conductivity of the α -Fe_{2-x}Cu_xO₃ sensor increases with increasing doped Cu concentration.

3.4. CH₄ sensing properties of the α -Fe_{2-x}Cu_xO₃ gas sensors

Fig. 6 depicts CH₄ gas response of the α -Fe_{2-x}Cu_xO₃ gas sensors in an atmosphere containing CH₄ (2000 ppm) at 25 °C and 50% relative humidity (RH); the inset shows the gas response of the undoped α -Fe₂O₃ and α -Fe_{1.92}Cu_{0.08}O₃ gas sensors to CH₄ with different concentrations at 25 °C and 50% RH. The undoped α - $Fe₂O₃$ nanoparticles have a lower response to 2000 ppm CH₄ gas at room temperature. In contrast, the response of the α -Fe_{2-x}- $Cu_xO₃$ (0 < x \leq 0.17) gas sensor is significantly higher at room temperature and at the same concentration of $CH₄$ gas. The maximum response to 2000 ppm $CH₄$ at room temperature was obtained when x in α -Fe_{2-x}Cu_xO₃ \approx 0.10. Although the maximum response is only \sim 1.06, this material is also a potential candidate for methane gas sensor applications because the working temperature is much lower in the present case. The sensor using α -Fe_{2-x}Cu_xO₃ nanoparticles as gas sensing material exhibits a receivable response to $CH₄$ at room temperature. The inset in Fig. 6 indicates that the response increased almost linearly with increasing concentration of CH₄ gas from 500 to 4000 ppm, meeting the common requirements in application. Paper
 $\frac{1}{2}$
 $\frac{1$

Moreover, for environmental monitoring of methane emissions at room temperature, the selectivity of the α -Fe_{2-x}Cu_xO₃ gas sensors was also evaluated. Fig. 7a shows the response of the α -Fe_{2-x}Cu_xO₃ gas sensors to different test gases (1000 ppm), *i.e.*, CO₂, C₂H₅OH and NH₃, at 25 °C and 50% RH. In the CO₂

Fig. 6 CH₄ gas response of the α -Fe_{2-x}Cu_xO₃ gas sensors in an atmosphere containing CH₄ (2000 ppm) at 25 °C and 50% RH. The inset shows the gas response of undoped α -Fe₂O₃ and α - $Fe_{1.92}Cu_{0.08}O₃$ gas sensors to CH₄ with different concentrations at 25 °C and 50% RH

Fig. 7 (a) Response of the α -Fe_{2-x}Cu_xO₃ gas sensors to different test gases at 25 °C and 50% RH. (b) Effect of humidity on the sensor response to 1000 ppm CH₄ at 25 °C.

Fig. 8 Schematic explaining the methane sensing mechanism of α -Fe_{2-x}Cu_xO₃ nanoparticles

sensing testing, only 700 ppm $CO₂$ was injected because clean air contains around 300 ppm $CO₂$. This shows that the response of the sensors to CH_4 is the highest, indicating that the α -Fe_{2-x}Cu_xO₃ sensor has good selectivity for CH₄, even though it exhibits a certain response to C_2H_5OH . As expected, Cu doping can significantly improve the selectivity of the sensor for CH4. Fig. 7b displays the effect of humidity on the sensor response at 25 °C. Water vapors in the atmosphere had an evident effect on the performance of the α -Fe_{2-x}Cu_xO₃ sensor; the response to $CH₄$ was higher in dryer air than in a humid environment. The adsorption of water affects the electronic properties of α -Fe_{2-x}Cu_xO₃, usually acting as a donor. Thus, long exposure in a humid environment can lead to hydration of the surface layer, and a corresponding drift of the sensor performance.¹⁷ However, avoiding or mitigating the impact of water vapor is a major problem for gas sensors working at room temperatures. Although some coatings, for example, Teflon, have been used to either consume water vapor or permit the passage of selected gases to the sensor,¹⁸ further related research is needed.

The CH₄ sensing mechanism (depicted in Fig. 8) of α - $Fe_{2-x}Cu_{x}O_{3}$ nanoparticles is a surface controlled process and can be understood as follows. In vacuum, there are a great number of unstable active sites on the surface of the p-type α -Fe_{2-x}Cu_xO₃ semiconductor, with holes as majority carriers. When α -Fe_{2-x}Cu_xO₃ nanoparticles are exposed to air, a certain

amount of oxygen from the air is adsorbed on the surface of α -Fe_{2-x}Cu_xO₃ in the form of O₂⁻ or O⁻, by transferring electrons from the conduction band to the adsorbed oxygen atoms. In this process, the formation of chemisorbed oxygen species results in a decrease in the free electron concentration in the material conduction band. Consequently, the conductivity of the p-type semiconductor will increase.^{10,11} It should be noted that the amount of chemisorbed oxygen species may be affected, even decreased, with the increasing adsorption of water vapor on the surface of α -Fe_{2-x}Cu_xO₃, which is not conducive to improving the gas sensing performance. Once the α -Fe_{2-x}Cu_xO₃ nanoparticles are exposed to an atmosphere containing CH4, surface reaction between the adsorbed oxygen species and CH₄ molecules will occur, resulting in the release of electrons trapped in the ionized oxygen species back into the materials and electron–hole recombination, thereby decreasing the concentration of hole carriers and lowering the measured conductivity.

4. Conclusion

 α -Fe_{2-x}Cu_xO₃ ($0 \le x \le 0.17$) nanoparticles were synthesized by an improved homogenous co-precipitation method. The morphological and structural characteristics showed that a- $Fe_{2-x}Cu_{x}O_{3}$ (0 < $x \le 0.17$) nanoparticles with an average particle size of \sim 40 nm also have a single phase with a rhombohedral

corundum structure. Owing to the substitution of Cu^{2+} at Fe^{3+} sites, the lattice parameters of α -Fe_{2-x}Cu_xO₃ increase with increasing doped Cu concentration. The shift of Raman peaks for α -Fe_{2-x}Cu_xO₃ to higher wavenumbers was observed due to the strong electron–phonon interaction and structural distortion after doping Cu. Doping Cu can also increase the concentration of hole carriers and enhance the conductivity of p-type a- $Fe₂O₃$ semiconductor. The CH₄ sensing characterization show that the α -Fe_{2-x}Cu_xO₃ nanoparticles are sensitive and have good selectivity to CH_4 at room temperature, and the response of the α -Fe_{2-x}Cu_xO₃ (0 < x ≤ 0.17) gas sensor is significantly improved by doping Cu. The maximum response to 2000 ppm $CH₄$ at room temperature and 50% RH was obtained when x in α - $Fe_{2-x}Cu_xO₃ \approx 0.10$, meeting the common requirements in application. Based on these results, the α -Fe_{2-x}Cu_xO₃ (0 < x \leq 0.17) nanoparticles can be considered potential candidates for methane detection at room temperature.
