# Chelating magnetic nanocomposite for the rapid removal of Pb(II) ions from aqueous solutions: characterization, kinetic, isotherm and thermodynamic studies

Atefeh Moradi,<sup>a</sup> Peyman Najafi Moghadam,<sup>\*b</sup> Reza Hasanzadeh<sup>b</sup> and Mika Sillanpää<sup>cd</sup>

In this study, a Fe<sub>3</sub>O<sub>4</sub>@GMA–AAm magnetic nanocomposite was synthesized as a novel adsorbent with a suitable core–shell structure, high adsorption capacity (158.73 mg g<sup>−1</sup>), easy separation and rapid adsorption rate. For this purpose, Fe<sub>3</sub>O<sub>4</sub> NPs were first reacted with 3-aminopropyltriethoxysilane for the preparation of MNPs–NH<sub>2</sub>. Then the MNPs–NH<sub>2</sub> was allowed to react with glycidylmethacrylate to form Fe<sub>3</sub>O<sub>4</sub>–GMA. Finally Fe<sub>3</sub>O<sub>4</sub>@GMA–AAm was synthesized by grafting polyacrylamide onto the Fe<sub>3</sub>O<sub>4</sub>–GMA using a radical polymerization process. The morphology and characteristics of the adsorbent were examined by various techniques such as FT-IR, TEM, SEM, XRD, AFM, TGA, EDX, EMA and VSM analysis. The synthesized adsorbent was used for the removal of Pb<sup>2+</sup> ions from aqueous media and the effect of different parameters (pH, adsorbed dosage, temperature, etc.) was investigated. The isotherm analysis indicated that the adsorption experimental data fitted very well with the Langmuir isotherm model. Two kinetics equations were used to describe the adsorption rate. The result showed that the pseudo-second-order model had a better fit with the experimental data, so the chemical adsorption was the rate controlling step of the adsorption process. The thermodynamic parameters for adsorption of Pb<sup>2+</sup> ions onto the Fe<sub>3</sub>O<sub>4</sub>@GMA–AAm adsorbent showed that the adsorption was endothermic in nature and spontaneous.

## 1. Introduction

Nowadays, by increasing industrial activities, numerous hazardous heavy metal ions are discharged into natural water resources. This environmental pollution occurs through military, industrial, and agricultural processes and waste disposal.<sup>1,2</sup> The presence of these toxic metal ions in wastewater and surface water is becoming a serious problem even at trace levels,<sup>3</sup> because of their adverse effects on aquatic ecosystems, the environment and human safety.<sup>4</sup> Heavy metal ions can accumulate in the environment and food chain which can be a major concern due to their progressive toxic effects and heavy metal poisoning. Also unlike some organic pollutants, they are not biodegradable and cannot be metabolized or decomposed.<sup>5,6</sup> Mental confusion, memory loss, fatigue and rashes are

the problems that associated with the accumulation of heavy metal ions in the human body. Therefore, simple and efficient removal of heavy metal ions from water and various industrial effluents is very important and has given rise to considerable amounts of research and practical concern.<sup>7</sup> Among the various toxic metal ions, lead is one of the most significant pollutants that is noxious to aquatic life and deleterious to human safety and may cause adverse health effects such as hepatitis, anaemia, nephritic syndrome, mental retardation, headache, dizziness, irritability and muscle deterioration.<sup>8</sup> Thus it is especially important and necessary to completely remove or reduce to an acceptable the level of Pb<sup>2+</sup> ions.

To cleanse water resources of toxic metal ions like Pb<sup>2+</sup> ions various treatment techniques have been used including chemical precipitation, liquid–liquid extraction, filtration, electrochemical treatment, ion exchange, membrane separation, adsorption, etc.<sup>9</sup> Among the widely used methods, adsorption is preferred due to its flexibility in design,<sup>10</sup> lower cost, high efficiency and the availability of various adsorbents.<sup>11</sup> Furthermore, because of the reversible nature of many adsorption processes, using suitable desorption processes, adsorbents can easily be regenerated to that these processes have high efficiency, low maintenance cost and ease of operation for multiple uses.<sup>12</sup> A good adsorbent should generally have a high surface area and

short equilibrium time in adsorption process, so that it can remove large amounts of contaminants in shorter amounts of time. In addition, it should generate a minimum amount of sludge and by-product.<sup>13</sup> Among the adsorbent materials developed polymeric nanomaterials can be key resolvers.<sup>14</sup> Nanotechnology has been considered one of the most important progress in science and technology<sup>15</sup> and its advances has shown that by decreasing the adsorbents size to nanometer may significantly increase the number of adsorption sites and raise the adsorption capacity.<sup>16</sup> Various adsorbents with significant adsorption capacity have been developed. Among them, magnetic nanoparticles ( $\text{Fe}_3\text{O}_4$ ), have attracted much attention and are widely used because of their simplicity and being easy to use.<sup>17</sup> However, it must be conceded that pure  $\text{Fe}_3\text{O}_4$  is highly sensitive to oxidation when exposed to the atmosphere because of its small size and is not suitable for samples with complicated matrices. To overcome these problems and improve the applicability of MNPs in real wastewater the surface of  $\text{Fe}_3\text{O}_4$  nanoparticles needs to be coated with polymer compounds with suitable functional groups.<sup>18</sup> A combination of polymers with magnetic particles can prevent direct contact between the magnetic substance and the environment, thus leading to improved chemical stability and reduced toxicity.<sup>19,20</sup> Mo and co-workers have reported on carbon-coated magnetic nanoparticles for the preparation of porous carbon@ $\text{Fe}_3\text{O}_4$  magnetic composites (PCMCs). The experimental conclusion was compared with the  $\text{Fe}_3\text{O}_4$  nanoparticles and PCMCs as prepared to establish ascertain the removal capacity of  $\text{Cr}(\text{vi})$ .<sup>21</sup> Huang and Chen reported a magnetic adsorbent which has been prepared binding polyacrylic acid (PAA) on the surface of  $\text{Fe}_3\text{O}_4$  NPs and the following amino-functionalization with diethylenetriamine (DETA) through carbodiimide activation. For this adsorbent the maximum adsorption capacity of  $\text{Cr}(\text{vi})$  was only  $11.24 \text{ mg g}^{-1}$ .<sup>22</sup> Ethylenediamine-functionalized magnetic polymer as an adsorbent for the removal of  $\text{Cr}(\text{vi})$  from aqueous solutions was reported by Gang and co-workers. In this work for suspension polymerization, glycidylmethacrylate (GMA) was used as a functional monomer. It was found that with increasing usage of GMA the adsorption capacity of  $\text{Cr}(\text{vi})$  increased.<sup>23</sup> Xiaoli *et al.* synthesized the magnetic  $\text{Fe}_3\text{O}_4$ @-silica-xanthan gum composites and systematically tested for the adsorptive removal of  $\text{Pb}^{2+}$  ions from aqueous solution in a batch mode.<sup>24</sup>

In the present study, a novel magnetic nano-adsorbent was synthesized by modification of  $\text{Fe}_3\text{O}_4$  and grafting of poly(acrylamide) onto the surface of modified  $\text{Fe}_3\text{O}_4$  nanoparticles. For this purpose the nanoparticle surface was first modified through silylation reaction with 3-aminopropyl triethoxysilane (APTES) and this compound with terminal amino groups was allowed to react by glycidylmethacrylate (GMA) monomer to generate the vinyl-containing moieties on the nanoparticle surface. Finally, acrylamide (AAM) was polymerized on the surface of vinyl-containing nanoparticles to prepare the final nano-adsorbent. The synthesized chelating magnetic adsorbent was characterized by Fourier Transform Infrared (FT-IR) spectroscopy, Transmission Electron Microscopy (TEM), X-Ray Diffraction (XRD), Vibrating Sample Magnetometry (VSM),

Thermogravimetric Analysis (TGA), Scanning Electron Microscopy (SEM), Energy Dispersive Spectrometer (EDX) and Element Mapping Analysis (EMA). The influences of different parameters (pH, contact time, agitation rate, temperature, adsorbent dosage and initial concentration of  $\text{Pb}^{2+}$  ions) on the adsorption process were studied. We also studied the kinetics, adsorption isotherms, kinetics and thermodynamic parameters to understand the mechanism of the synthesized MNPs for the absorption of metal ions.

## 2. Experimental

### 2.1. Materials

Glycidylmethacrylate (GMA) was obtained from Daejung Chemicals and Metals Company (South Korea) and distilled under reduced pressure to remove their inhibitor.  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ , acrylamide (AAM) and 3-aminopropyltriethoxysilane (APTES) were used without further purification (Merck). Benzoyl peroxide (BPO) was purchased from Merck and recrystallized from boiling methanol. Analytical-reagent grade  $\text{Pb}(\text{NO}_3)_2$ , other organic solvents and inorganic chemicals including tetrahydrofuran (THF),  $\text{AlCl}_3$ , HCl, NaOH and ammonium hydroxide ( $\text{NH}_4\text{OH}$ ) were purchased from Sigma Aldrich.

### 2.2. Instrumentation

Fourier transform infrared (FT-IR) spectra were measured with a Nexus 670, Thermo Nicolet (USA) spectrophotometer. X-ray diffraction (XRD) was measured on an X'Pert Pro an X-ray photoelectron spectrometer (Netherlands) using nonmonochromated Cu K $\alpha$  radiation as an excitation source. A vibrating sample magnetometer (VSM; Lakeshore Cryotronics, Westerville, OH, USA) was used for measuring the magnetic properties of the prepared samples. The morphology of the magnetic adsorbent was examined with two types of scanning electron microscopy (SEM), (LEO 1430VP, Germany and MIRA3 TESCAN, Czech Republic). The size and structure were investigated by transmission electron microscopy (TEM), (Philips CM30 300 kV). The surface components of the samples were analysed using energy dispersive spectrometer (EDX) and element mapping analysis (EMA) (XL30 Philips Company, Netherlands). TGA analyses of the samples were done using the NETZSCH (Germany)-200 F 3 Maia by scanning to  $600^\circ\text{C}$  with a heating rate of  $10^\circ\text{C min}^{-1}$ . The concentrations of the metal ions in the solution were measured with an atomic absorption spectrophotometer (AAS) (Analytic Jenanov AA 400).

### 2.3. Preparation of $\text{Fe}_3\text{O}_4$ nanoparticles (MNPs)

The  $\text{Fe}_3\text{O}_4$  nanoparticles were prepared with the coprecipitation method<sup>25</sup> ammonium hydroxide (30 mL) with deionized water (20 mL) was deoxygenated in a flask by bubbling Ar for 20 min. In another beaker, 5.41 g  $\text{FeCl}_3$  and 2.99 g  $\text{FeCl}_2$  were dissolved in 50 mL deionized water. Then, the solution obtained was added drop-wise into the above-mentioned alkaline solution under vigorous stirring at  $60^\circ\text{C}$ . Ferrous and ferric chloride were allowed to react in ammonium

hydroxide solution by alkaline co-precipitation and a black precipitate was obtained. The black precipitate which formed was called magnetite ( $\text{Fe}_3\text{O}_4$ ) and harvested by magnetic bar, then washed several times with deionized water and finally dried in a vacuum oven at  $50^\circ\text{C}$  for 24 h. Then the obtained  $\text{Fe}_3\text{O}_4$  nanoparticles were used for the next step in the synthesis of the magnetic nanocomposite. The chemical reactions for precipitation of  $\text{Fe}_3\text{O}_4$  are expressed as follows:

The overall reaction can be written as:

#### 2.4. Preparation of MNPs- $\text{NH}_2$

Modified  $\text{Fe}_3\text{O}_4$ -NPs (MNPs- $\text{NH}_2$ ) was achieved through a reaction between APTES and the hydroxyl groups on the surface of the magnetite. Therefore obtained  $\text{Fe}_3\text{O}_4$ -NPs (2.00 g) powder was dispersed in pure ethanol (140 mL) by sonication under Ar atmosphere for about 40 min. Then the APTES (4 mL) was added into the mixture and the mixture was sonicated for 1 h. After that the mixture was heated at  $50^\circ\text{C}$  under magnetic stirring for 20 h. The resulting modified MNPs were washed with acetone and deionized water several times. Finally the product was dried in vacuum oven at  $60^\circ\text{C}$  for 24 h.

#### 2.5. Synthesis of modified MNPs- $\text{NH}_2$ with GMA

The MNPs- $\text{NH}_2$  (1.50 g) and GMA (6.00 g) were added into 40 mL dry THF in a two-necked flask equipped with ultrasonic

probe and inlet and outlet of inert gas. The mixture was sonicated for 20 min to obtain a uniform mixture. Finally aluminium trichloride ( $\text{AlCl}_3$ ) as a Lewis acid was added and the reaction was carried out by stirring at  $30^\circ\text{C}$  for 7 days. The product was separated using external magnet and washed several times with methanol and ether. The obtained  $\text{Fe}_3\text{O}_4$ -GMA was dried in a vacuum oven at  $40^\circ\text{C}$  for 24 h.

#### 2.6. Synthesis of magnetic nanocomposite ( $\text{Fe}_3\text{O}_4$ @GMA-AAm)

For the synthesis of  $\text{Fe}_3\text{O}_4$ @GMA-AAm magnetic nanocomposite, grafting of polyacrylamide onto the  $\text{Fe}_3\text{O}_4$ -GMA surface was done in THF solvent. For this purpose,  $\text{Fe}_3\text{O}_4$ -GMA (1.00 g) was added to THF (30 mL) in a two-necked flask equipped with ultrasonic probe and inlet and outlet of inert gas and sonicated for 20 min. Acrylamide monomer (2.00 g) and BPO initiator were added to the mixture and the polymerization reaction was carried out by stirring at  $80^\circ\text{C}$  for 20 h. The product obtained was retained by an external magnet and washed with  $\text{H}_2\text{O}$  and methanol to remove unreacted monomer. Finally, the synthesized magnetic nanocomposite was dried in a vacuum oven at  $60^\circ\text{C}$  for 24 h.

### 3. Results and discussion

The  $\text{Fe}_3\text{O}_4$ @GMA-AAm magnetic nanocomposite was synthesized by grafting polyacrylamide onto the surface of  $\text{Fe}_3\text{O}_4$ -GMA with a radical polymerization process. For this purpose firstly the  $\text{Fe}_3\text{O}_4$  nanoparticles were prepared with co-precipitation method using  $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$  and  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  in a molar ratio of 1 : 2. Then the hydroxyl groups on the surface of  $\text{Fe}_3\text{O}_4$  were allowed to react with APTES for the preparation of MNPs- $\text{NH}_2$ . After that the MNPs- $\text{NH}_2$  was allowed to react with the epoxy group of GMA to form  $\text{Fe}_3\text{O}_4$ -GMA. The products were

Scheme 1 Synthetic diagram of the  $\text{Fe}_3\text{O}_4$ @GMA-AAm nanocomposite.

characterized by various techniques as mentioned described below. The overall synthetic procedure was presented in Scheme 1.

### 3.1. FT-IR spectroscopy

FT-IR spectroscopy was used to show the structure of the pure  $\text{Fe}_3\text{O}_4$  (A),  $\text{Fe}_3\text{O}_4$ -APTES (B), GMA (C),  $\text{Fe}_3\text{O}_4$ @GMA (D) and  $\text{Fe}_3\text{O}_4$ @GMA-AAm (E) magnetic nanocomposites. From the IR spectra presented in Fig. 1, the strong absorption peaks at  $585\text{ cm}^{-1}$  belonged to the stretching vibration mode of Fe-O from the magnetic nanoparticles cores<sup>7</sup> and two peaks at  $3430$  and  $1650\text{ cm}^{-1}$  are attributed to the stretching and bending vibrations of the O-H group respectively.<sup>26</sup> The introduction of APTES onto the surface of the  $\text{Fe}_3\text{O}_4$ -NPs was confirmed by the bands at  $1115$  and  $1060\text{ cm}^{-1}$  assigned to the Si-O-Si stretching vibrations. The two broad bands at  $3446$  and  $1670\text{ cm}^{-1}$  can be attributed to the N-H stretching vibration and  $\text{NH}_2$  bending vibration of free  $\text{NH}_2$  group respectively.<sup>27</sup> Furthermore, hydrogen bonds of terminal  $\text{NH}_2$  silanols and C-N band also appeared at around  $3270$  and  $1290\text{ cm}^{-1}$ . The presence of the

propyl group was confirmed by C-H asymmetric stretching vibration and symmetric stretching vibration that appeared at  $2930$  and  $2841\text{ cm}^{-1}$ .<sup>4</sup> Compared to the IR spectrum (C), the IR spectrum (D) of GMA and  $\text{Fe}_3\text{O}_4$ @GMA, the asymmetrical and symmetrical stretching due to the methyl and methylene groups were observed at  $2995$  and  $2939\text{ cm}^{-1}$ . The stronger absorption band at  $1740\text{ cm}^{-1}$  was attributed to the ester carbonyl stretching of monomer GMA units, evidence that the GMA were successfully grafted onto  $\text{Fe}_3\text{O}_4$ -APTES nanoparticles. Another band seen at  $905\text{ cm}^{-1}$  was related to the asymmetric stretching of the epoxy group.<sup>28</sup> The bands at  $1174$  and  $1289\text{ cm}^{-1}$  were attributed to the ester C-O symmetric stretching of GMA. However, the identification of a peak attributable to the stretching vibrations of the epoxy groups from GMA with the symmetric stretching and asymmetric stretching vibrations was problematic due to the overlapping of the peaks of Si-O groups.<sup>10</sup> The spectrum of the  $\text{Fe}_3\text{O}_4$ @GMA (D) and  $\text{Fe}_3\text{O}_4$ @GMA-AAm (E) showed a peak at  $2926\text{ cm}^{-1}$  due to C-H bonds of aliphatic chain stretching vibrations. The broad band at  $3433\text{ cm}^{-1}$  corresponds to the hydrogen bonded O-H and N-H

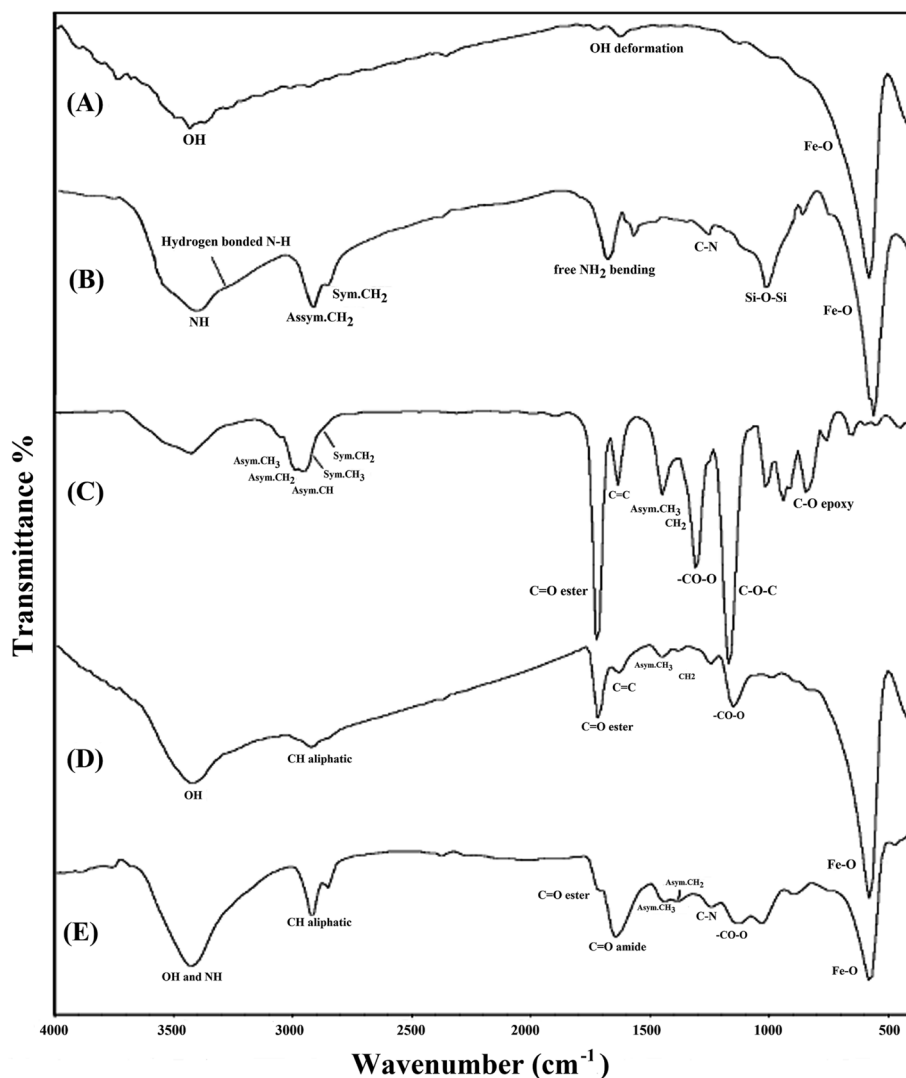

Fig. 1 FT-IR spectra of the pure  $\text{Fe}_3\text{O}_4$  (A),  $\text{Fe}_3\text{O}_4$ -APTES (B), GMA (C),  $\text{Fe}_3\text{O}_4$ @GMA (D) and  $\text{Fe}_3\text{O}_4$ @GMA-AAm nanocomposites (E).

stretching vibration of AAm. The peaks at 1650 and 1732  $\text{cm}^{-1}$  should be assigned to the stretching vibration of the amide and ester C=O respectively from both AAm and GMA. The absorption band at 1400  $\text{cm}^{-1}$  is due to the bending vibration of  $\text{CH}_2$  and  $\text{CH}_3$  groups.<sup>5</sup>

### 3.2. Particle size and morphology studies

The morphology of the magnetic nanocomposite ( $\text{Fe}_3\text{O}_4$ @GMA-AAm) was characterized by TEM, SEM and AFM techniques. The transmission electron microscope images are shown in Fig. 2. In this image two different areas can be seen, the dark areas may be represented magnetic monomer ( $\text{Fe}_3\text{O}_4$ ) while the bright ones are indications of amorphous polymers formed around the primary particles, so the core-shell structure has been clearly seen and can be taken as evidence of the successful synthesis of  $\text{Fe}_3\text{O}_4$ @GMA-AAm. The particle size deduced from the TEM images was about 70–150 nm.

The surface morphology of the samples was studied by SEM analysis. The SEM images of bare MNPs (A),  $\text{Fe}_3\text{O}_4$ @GMA (B) and synthesized nanocomposite (C) are given in Fig. 3. As can be seen in Fig. 3A, the MNPs are quasi-spherical in shape with the particle size about 45 nm, while Fig. 3B shows that the  $\text{Fe}_3\text{O}_4$ @GMA are greater in size than  $\text{Fe}_3\text{O}_4$  (about 64 nm) and attached to each other due to modification of the surface of the nanoparticles in two processes using APTES and GMA. The SEM

image of nanocomposite in Fig. 3C clearly shows the formation of final product and the growth of the polymer chains on the surface of the nanoparticles. The particle size of the nanocomposites was nearly 88 nm.

The morphology and three-dimensional shape (topography) study of the synthesized nanocomposite was investigated by AFM technique. As shown in Fig. 4A, the topography image clearly shows the polymer chains formed on the surface of the modified nanoparticles. Likewise in Fig. 4B, a phase contrast demonstrates the heterogeneity in the sample that it was due to different structural components in the nanocomposite.

### 3.3. XRD

The crystalline structure of the  $\text{Fe}_3\text{O}_4$  nanoparticles before and after surface modification and polymer coating was identified by XRD, and the results were displayed in Fig. 5. The intense diffraction peaks at ( $2\theta = 30.27^\circ, 35.63^\circ, 43.29^\circ, 53.64^\circ, 57.14^\circ, 62.73^\circ$  and  $74.25^\circ$ ), which corresponded to the (220), (311), (400), (422), (511), (440) and (533), indicated a cubic spinel structure of magnetite (Fig. 5A) which was matched to the standard XRD pattern of magnetite (JCPDS card, file no. 85-1436).<sup>29</sup> The same characteristic peaks were also observed for  $\text{Fe}_3\text{O}_4$ @GMA Fig. 5B and  $\text{Fe}_3\text{O}_4$ @GMA-AAm Fig. 5C, indicating that during the graft and polymerization process the crystalline phase of the  $\text{Fe}_3\text{O}_4$  nanoparticles was largely unchanged. The

Fig. 2 TEM images of synthesized nanocomposite in two different area.

Fig. 3 SEM images of the bare MNPs (A),  $\text{Fe}_3\text{O}_4$ @GMA (B) and synthesized nanocomposite (C).

Fig. 4 AFM images; three-dimensional shape (A) and phase contrast (B) of the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$ .

obvious difference at baseline of the XRD patterns of  $\text{Fe}_3\text{O}_4@\text{GMA}$  and nanocomposite with  $\text{Fe}_3\text{O}_4$  nanoparticles showed that the magnetite had been successfully coated by the amorphous structure. The average crystallite size of the materials prepared was obtained from the Debye-Scherrer equation<sup>30</sup>  $D = \frac{k\lambda}{\beta \cos \theta}$

where,  $k$  (0.89) is the Debye-Scherrer constant,  $\lambda$  (0.15406 nm) is the X-ray wavelength,  $\beta$  is the peak width of half-maximum,  $\theta$  is the Bragg's angle in degree and  $D$  is the average crystalline diameter which was estimated using the strongest peak. In these cases the strongest peak in the three XRD patterns was (3

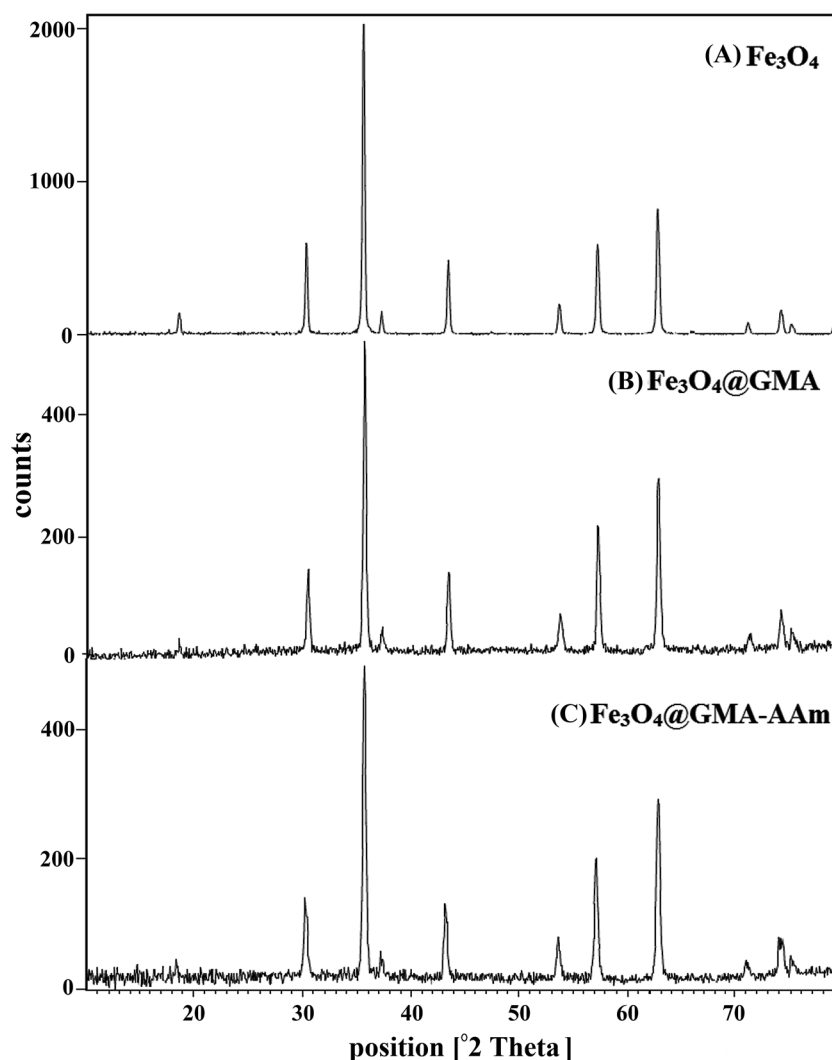

Fig. 5 XRD patterns of the magnetite (A),  $\text{Fe}_3\text{O}_4@\text{GMA}$  (B),  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  (C).

1) at  $2\theta = 35.63^\circ$ . The calculated diameters of the  $\text{Fe}_3\text{O}_4$ ,  $\text{Fe}_3\text{O}_4@\text{GMA}$  and  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  were seen to be respectively 35.5, 43.75 and 78.84 nm.

### 3.4. Magnetic measurements

Magnetic measurements of the naked  $\text{Fe}_3\text{O}_4$ ,  $\text{Fe}_3\text{O}_4@\text{GMA}$  and  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  were studied with the VSM at room temperature. The hysteresis loops of the three tested nanoparticles are shown in Fig. 6. The magnetic saturation ( $M_s$ ) values obtained for the  $\text{Fe}_3\text{O}_4$ , the  $\text{Fe}_3\text{O}_4@\text{GMA}$  and the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  were respectively 80.53, 71.86 and 66.76  $\text{emu g}^{-1}$ .<sup>27</sup> It can also be observed from this figure that magnetization of pure  $\text{Fe}_3\text{O}_4$  nanoparticles decreased slightly after surface modification with GMA and the coating of the polymer shell on the modified  $\text{Fe}_3\text{O}_4$  core. This decrease may be due to the small quenching of the magnetic moment by interplay between the coated layers and the  $\text{Fe}_3\text{O}_4$  surface.<sup>29</sup> This is another proof of successful coating of the GMA and the polyacrylamide onto the surface of the  $\text{Fe}_3\text{O}_4$  nanoparticles. The magnetic property of the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  was still strong enough to be rapidly separated (10 s) from the solution compared to other reported nanocomposites based on  $\text{Fe}_3\text{O}_4$  (Table 1) using an external magnetic field (Scheme 2).

### 3.5. TGA analysis

The thermal stability of the  $\text{Fe}_3\text{O}_4@\text{GMA}$  and the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  was investigated by the TGA analysis (Fig. 7). For both of the samples, upon heating from  $50^\circ\text{C}$  to  $200^\circ\text{C}$ , the TGA curves showed a weight loss of about 10% which can be due to the loss of moisture.<sup>15</sup> As shown in Fig. 7A, which is related to the  $\text{Fe}_3\text{O}_4@\text{GMA}$ , the weight loss ( $200\text{--}800^\circ\text{C}$ ) is attributed to the decomposition of the coated GMA onto the surface of the  $\text{Fe}_3\text{O}_4$  nanoparticles (about 15%). The  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  thermogram (Fig. 7B) showed a higher weight loss than the  $\text{Fe}_3\text{O}_4@\text{GMA}$  (about 45%) because of the loss of GMA and polyacrylamide components formed onto the surface of the  $\text{Fe}_3\text{O}_4$  nanoparticles.

### 3.6. SEM, EDX and EMA analyses before and after $\text{Pb}^{2+}$ ions adsorption

The SEM micrographs of the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite after adsorption of  $\text{Pb}^{2+}$  ions are given in Fig. 8. The SEM images clearly show uniform particles with angular shape. During the adsorption process these particles join together making large particles ( $\sim 200$  nm), thereby increasing the size of particles after adsorption is apparent with respect to the size of particles before adsorption (88.09 nm).

Fig. 6 Magnetization curves of the naked  $\text{Fe}_3\text{O}_4$ ,  $\text{Fe}_3\text{O}_4@\text{GMA}$  and  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite.

Table 1 Comparison of saturation magnetization, recovery time and adsorption capacity

Adsorbents	Time (s)	$M_s$ ( $\text{emu g}^{-1}$ )	$q_{\text{max}}$ ( $\text{mg g}^{-1}$ )	Reference
$\text{Fe}_3\text{O}_4@\text{silica-xanthan gum composites}$	180 s	32.84	21.32	24
$\text{Fe}_3\text{O}_4@\text{SiO}_2$ core-shell magnetic nanomaterial	120 s	34	76.59	31
$\text{Fe}_3\text{O}_4@\text{DAPT}$ core-shell ferromagnetic nanorods	25 s	56.1	83.3	32
$\text{Fe}_3\text{O}_4\text{-SiO}_2\text{-poly(1,2-diaminobenzene)}$ core-shell sub-micron particles	20 s	60	$\sim 65$	26
DHPCT@ $\text{Fe}_3\text{O}_4$ MNPs	15 s	24.7	52.1	33

Scheme 2 Magnetic separation of the  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  nanocomposite particles by an external magnet.

Fig. 7 TGA curves of the  $\text{Fe}_3\text{O}_4\text{@GMA}$  (A) and the  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  (B) nanocomposites.

The chemical composition of the  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  nanocomposite was analysed by EDX before and after the adsorption of  $\text{Pb}^{2+}$  ions onto the nanocomposite surface. The EDX pattern before adsorption clearly showed the presence of Fe, O, N and C (Fig. 9A). After the adsorption of  $\text{Pb}^{2+}$  ions, the appearance of lead peaks along with Fe, O, N and C peaks in the EDX spectrum

confirms that the  $\text{Pb}^{2+}$  ions were taken up onto the surface of prepared adsorbent.

The elemental mapping analysis by EDX was shown in Fig. 10, that was used for the analysis of the chemical composition and determination of elements. These images indicate the distribution and presence of Fe, O, N, C elements on the surface of the nanocomposite before and after adsorption (Fig. 10A). Also, after adsorption the images of the nanocomposite show the presence of a Pb element, which corroborates the adsorption of the  $\text{Pb}^{2+}$  ions by the synthesized magnetic adsorbent (Fig. 10B).

**3.6.1. Batch adsorption experiments.** Adsorption of the  $\text{Pb}^{2+}$  ions by the  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  nanocomposite was measured from batch adsorption experiments by mixing 10 mg of adsorbent with an aqueous solution containing a pre-determined concentration of  $\text{Pb}^{2+}$  ions (50 mL). The mixture was shaken at 200 rpm to reach equilibrium. After a specified time, the solid and liquid were separated by external magnet and the concentrations of  $\text{Pb}^{2+}$  ions were measured by AAS. To find the optimized pH in adsorption of  $\text{Pb}^{2+}$  ions the effect of the pH was studied. The initial pH of the solutions was adjusted in the range of 2.0–7.0 by adding 0.1 N HCl or 0.1 N NaOH solution at 25 °C. The effect of the dosage of adsorbent on the adsorption was also determined with different nanocomposites dosages (0.005–0.03 g/50 mL  $\text{Pb}^{2+}$  ions, 10 mg  $\text{L}^{-1}$ ). The Langmuir, Freundlich and Dubinin–Radushkevich (D–R) adsorption isotherms were studied at different temperatures, namely 15,

Fig. 8 SEM micrographs of the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite after  $\text{Pb}^{2+}$  ions adsorption.

Fig. 9 EDX pattern of the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite before (A) and after (B)  $\text{Pb}^{2+}$  ions adsorption.

25, 35 and 45 °C (the adsorbent dosage 0.007 g in 50 mL  $\text{Pb}^{2+}$  ions solution) with constant shaking (200 rpm). The effect of contact time between solution and adsorbent was also investigated to analyse the adsorption kinetics at a pH of 6 at room temperature. The kinetics of the adsorption process were carried out by adding 0.007 g of adsorbent into 50 mL of 10 mg  $\text{L}^{-1}$   $\text{Pb}^{2+}$  ions solution, at different times at 25 °C. For the kinetic study, pseudo-first-order and pseudo-second-order models were studied.

The concentrations of the metal ions in the adsorption solutions were determined by AAS. According to the experimental results obtained, a mechanism which can be proposed for the adsorption of  $\text{Pb}^{2+}$  ions on the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  surface was shown in Scheme 3.

The equilibrium adsorption capacity ( $q_e$ ) ( $\text{mg g}^{-1}$ ) for  $\text{Pb}^{2+}$  ions was calculated according to the following equation:

$$q_e = \frac{(C_0 - C_e)V}{m} \quad (1)$$

where  $C_0$  and  $C_e$  ( $\text{mg L}^{-1}$ ) are respectively the initial and equilibrium  $\text{Pb}^{2+}$  ions aqueous concentrations.  $V$  is the volume (mL) of  $\text{Pb}^{2+}$  ions aqueous solution;  $m$  is the mass (mg) of adsorbents

used in the experiment. The removal percentage of metal ions was calculated using the following equation:

$$\% R = 100 \frac{(C_0 - C_e)}{C_0} \quad (2)$$

### 3.7. Adsorption study of the $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$ adsorbent

**3.7.1. Effect of pH value.** The pH value of the media is one of the most important factors in the adsorption of metal ions. It is well known that  $\text{Pb}^{2+}$  ions are present in several forms in media depending on the pH solution: these are  $\text{Pb}^{2+}$ ,  $\text{Pb}(\text{OH})^+$ ,  $\text{Pb}(\text{OH})_2$ , and  $\text{Pb}(\text{OH})_3$ .<sup>34</sup> The effect of pH on the adsorption of  $\text{Pb}^{2+}$  ions with  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite was investigated in pH ranges between 2.0 and 7.0 at 25 °C with an initial  $\text{Pb}^{2+}$  ions concentration of 10 mg  $\text{L}^{-1}$ . The results showed that the adsorption of  $\text{Pb}^{2+}$  ions in solution completely depends on pH, in fact in acidic pH the  $\text{H}^+$  ions competes with the  $\text{Pb}^{2+}$  ions to reach functional groups of synthesized composite. Thus the adsorption of  $\text{Pb}^{2+}$  ions in acidic media is low. Therefore the efficient removal of the  $\text{Pb}^{2+}$  ions appeared at pH 6.0 and reached a constant state up to pH 7.0. It can be said that at pH around 6.0  $\text{Pb}^{2+}$  ions are the main element substance in the

Fig. 10 EDX elemental mapping of the  $Fe_3O_4@GMA-AAm$  nanocomposite before (A) and after (B)  $Pb^{2+}$  ions adsorption. The images indicate that the atomic symbols correspond to the EDX.

solution. When the pH is above 6.0 the solubility of  $Pb(OH)_2$  is very low and the precipitation of lead ions prevails. The  $Fe_3O_4@GMA-AAm$  displayed a maximum  $Pb^{2+}$  ions removal efficiency of 99% at pH 6.0. Therefore pH 6 appeared to be the optimal condition and was chosen as the optimal pH for the

following experiments. The effect of pH on lead adsorption is shown in Fig. 11A.

**3.7.2. Effect of adsorbent dosage.** To determine the optimal adsorbent dose for the  $Pb^{2+}$  ions solution (50 mL) at an initial concentration of  $10\text{ mg L}^{-1}$ , various adsorbent dosages

Scheme 3 Schematic illustration of adsorption mechanism of the  $Fe_3O_4@GMA-AAm$  nanocomposite.

(0.005, 0.007, 0.01, 0.013, 0.02, 0.025 and 0.03 g) of synthesized  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  were added. The results of the experiments are presented in Fig. 11B. It can be seen that the efficient removal of metal ions increased from 97% to 99.5% with an increase in the dosage of adsorbent from 0.005 g to 0.01 g. Increasing the dose of adsorbent enabled the number of available adsorption sites to increase, so the removal percentage of  $\text{Pb}^{2+}$  ions increased. After that, as the dosage continued to increase, the adsorption levels reached a steady state value or possibly even started to decrease slightly. This result can be explained by the increased likelihood of contact between these small particles due to increased adsorbent dose and also to the shaking process in a horizontal shaker, leading to aggregation, thus as a result the total surface area and active sites of adsorbent decreased.<sup>35</sup> The optimal dosage of the nanocomposite for the adsorption of  $\text{Pb}^{2+}$  ions was therefore found to be about 0.007 g/50 mL.

**3.7.3. Effect of adsorption time.** The contact time between the metal ions and adsorbent plays an important role in the adsorption process and revealed the minimum time required for the removal of the maximum percentage of pollutants from the media. Fig. 12A shows the contact time vs. the removal percentage curves. It can be observed that the uptake of  $\text{Pb}^{2+}$  ions was very rapid and a large amount of this toxic ion was removed within a few minutes (2 min). The fast adsorption process may be the result of the fast kinetics of active sites on

the surface of the synthesized composite in the adsorption of  $\text{Pb}^{2+}$  ions along with a large number of accessible active adsorption sites on the uncovered absorbent surface.<sup>36</sup> After this time there was no significant change in terms of the amount of adsorption due to the saturation of the active sites on the absorbent surface. Therefore the equilibrium time for the synthesized nanocomposite was found to be about 2 min.

**3.7.4. Effect of initial concentration.** Solutions with different initial concentrations of  $\text{Pb}^{2+}$  ions (1, 5, 10, 20, 30, 50  $\text{mg L}^{-1}$ ) were used to study the effect of concentration variation on the removal of metal ions by 0.007  $\text{g L}^{-1}$  adsorbent at pH 6 and temperature 298 K. It can be seen from Fig. 12B that the removal yield decreased from 99 to 44% as the initial  $\text{Pb}^{2+}$  ions concentration increased. Therefore at a higher initial concentration of  $\text{Pb}^{2+}$  ions the adsorption was decreased due to the active sites of the adsorbent being rapidly occupied by metal ions and the number of accessible adsorption sites was reduced.<sup>32</sup>

**3.7.5. Effect of solution temperature.** Temperature plays an important role in the adsorption process as it provides valuable information on three basic thermodynamic parameters; the standard Gibbs free energy, enthalpy and entropy changes. The changes in these parameters were used to characterize the adsorption thermodynamics. In this study the  $\text{Pb}^{2+}$  ions adsorption experiment was performed with varying temperatures from 10 °C to 45 °C using 0.007 g of adsorbent and pH 6.

Fig. 11 Effect of pH (A) and adsorbent dosage (B) on  $\text{Pb}^{2+}$  ions adsorption by  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  (initial  $\text{Pb}^{2+}$  ions concentration: 10  $\text{mg L}^{-1}$ , agitation rate: 200 rpm, contact time: 2 min,  $T = 298 \text{ K}$ ).

Fig. 12 Effect of adsorption time (A) and initial concentration (B) on  $\text{Pb}^{2+}$  ions adsorption by the  $\text{Fe}_3\text{O}_4\text{@GMA-AAm}$  nanocomposite (adsorbent dose: 0.007 g/50 mL  $\text{Pb}^{2+}$  ions, agitation rate: 200 rpm, pH 6,  $T = 298 \text{ K}$ ).

Fig. 13 Effect of solution temperature (A) and agitation rate (B) on  $\text{Pb}^{2+}$  ions adsorption by the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite (initial  $\text{Pb}^{2+}$  ions concentration:  $10 \text{ mg L}^{-1}$ , contact time: 2 min, adsorbent dose:  $0.007 \text{ g/50 mL}$   $\text{Pb}^{2+}$  ions, pH 6).

Fig. 13A shows the removal percentage of  $\text{Pb}^{2+}$  ions which were adsorbed onto the nanoadsorbent at different temperatures. The results showed that adsorption increased slightly from 94.3 to 99.5% when the temperature increased from  $10^\circ\text{C}$  to  $25^\circ\text{C}$ . This result showed that the adsorption of the lead ions was an endothermic process. The increase in the adsorption with the increase in temperature may be due to the increase in the mobility of the ions, which can be probably increase the number of ions for interaction with active sites.<sup>37</sup> Raising the temperature to  $25^\circ\text{C}$  revealed no obvious variation for  $\text{Pb}^{2+}$  ions because in the whole range of temperature investigated the adsorption rate is about 99.5%.

**3.7.6. Effect of agitation rate.** Agitation speed is an effective parameter in the adsorption performance and influences the distribution of the solute in the solution. The effect of agitation rate on removal percentage efficiency for  $\text{Pb}^{2+}$  ions was studied by varying the rate of agitation from 100 to 300 rpm, while the other conditions were held constant. As shown in Fig. 13B, when the agitation rate increased to 200 rpm, the adsorption capacity also increased. This was due to the additional turbulence that raised the diffusion of the adsorbate ions into the internal surface of adsorbent. This also decreased the boundary layer thickness around the adsorbent particles.<sup>38</sup> Further increase in the agitation rate to 250 and 300 rpm reduced the adsorption capacity, because the extreme turbulence caused a decrease in the interplay time between the adsorbent and adsorbate ions. An agitation speed of 200 rpm was therefore selected as optimal.

**3.7.7. Effects of adsorption kinetics.** To investigate adsorption kinetics and describe the rate of the adsorption mechanisms of the  $\text{Pb}^{2+}$  ions onto the magnetic nanocomposite, two kinetic models were used to fit the experimental data. These models are the Lagergren pseudo-first-order and the Ho pseudo-second-order equations.<sup>39</sup> The Lagergren kinetic model describes the rate of adsorption proportional to the number of unoccupied sites by the solutes and is expressed in the following linear equation:

$$\log(q_e - q_t) = -\frac{k_1}{2.303}t + \log q_e \quad (3)$$

where  $q_e$  and  $q_t$  are the numbers of  $\text{Pb}^{2+}$  ions adsorbed ( $\text{mg g}^{-1}$ ) at equilibrium and at time  $t$  (min) respectively.  $k_1$  ( $\text{min}^{-1}$ ) is the pseudo-first-order adsorption kinetic constant.  $k_1$  and  $q_e$  can be obtained from the slope and intercept of  $\log(q_e - q_t)$  versus  $t$  (Fig. 14A). The Ho kinetic model based on adsorption equilibrium capacity assumes that the rate of possession for adsorption sites is proportional to the square of the number of unoccupied sites. The adsorption rate is dependent on the concentration of the activated sites on the surface of adsorbent. This model is expressed by the following equation:

$$\frac{t}{q_e} = \frac{1}{k_2 q_e^2} + \frac{1}{q_e} t \quad (4)$$

where  $k_2$  ( $\text{g mg}^{-1} \text{ min}^{-1}$ ) is the pseudo-second-order adsorption kinetic parameter and both  $k_2$  and  $q_e$  can be obtained from the intercept and slope of the graph of  $(t/q_t)$  versus  $t$  (Fig. 14B).<sup>36</sup> The

Fig. 14 Kinetic models of  $\text{Pb}^{2+}$  ions adsorption onto the nanocomposite using pseudo-first-order (A), and pseudo-second-order model (B).

**Table 2** Kinetic parameters for Pb<sup>2+</sup> ions adsorption using Fe<sub>3</sub>O<sub>4</sub>@GMA-AAm

Kinetic models and parameters	Pb <sup>2+</sup> ions
<b>Pseudo-first-order model</b>	
$q_{e,exp}$ (mg g <sup>-1</sup> )	70.71
$q_{e,cal}$ (mg g <sup>-1</sup> )	0.784
$k_1$ (min <sup>-1</sup> )	-0.0046
$R^2$	0.1284
NSD (%)	49.9
<b>Pseudo-second-order model</b>	
$q_{e,exp}$ (mg g <sup>-1</sup> )	70.71
$q_{e,cal}$ (mg g <sup>-1</sup> )	69.93
$k_2$ (g mg <sup>-1</sup> min <sup>-1</sup> )	1.02
$R^2$	1
NSD (%)	0.551

experimental data of two kinetic models are calculated and shown in Table 2. The rate constants, correlation coefficients ( $R$ ) and calculated  $q_e$  for the two kinetic models of nanocomposite showed that the fit of the pseudo-first-order model with the experimental was poor according to the low correlation coefficients. Also the calculated equilibrium adsorption capacities ( $q_{e,cal}$ ) digressed too much from the measured values ( $q_{e,exp}$ ). These results indicate that the applicability of the pseudo-second-order kinetic model with excellent correlation coefficients and good agreement between calculated  $q_e$  and measured  $q_e$ , is more appropriate to describe the adsorption process of Pb<sup>2+</sup> ions on the nanocomposite. Therefore it can be concluded that the adsorption of Pb<sup>2+</sup> ions onto Fe<sub>3</sub>O<sub>4</sub>@GMA-AAm perfectly obeyed the pseudo-second-order kinetic model and suggests chemical adsorption as the rate-controlling step of the adsorption mechanism.<sup>30</sup>

**3.7.8. Validity of the kinetic model.** In addition, the values of normalized standard deviation (NSD) (%) were also calculated to confirm the fitness of the kinetic models to the experimental data,<sup>40</sup> which is defined as:

$$NSD\% = \frac{\sqrt{\sum [(q_{e,exp} - q_{e,cal})/q_{e,exp}]^2}}{N - 1} \quad (5)$$

where  $N$  is the number of measurements,  $q_{e,exp}$  and  $q_{e,cal}$  (mg g<sup>-1</sup>) are the experimental and calculated equilibrium adsorption capacity values respectively. The parameters and measured

NSD (%) values for the two kinetic models are shown in Table 2. The NSD (%) values obtained for the pseudo-first-order model were higher than the NSD (%) values obtained for the pseudo-second-order model. Therefore the pseudo-second-order model was fitted with higher  $R^2$  to illustrate the adsorption kinetics of the Pb<sup>2+</sup> ions because a smaller NSD (%) value indicates a better fitting kinetic model.

**3.7.9. Adsorption isotherms.** To understand the adsorption mechanism of Pb<sup>2+</sup> ions on the adsorbent, the adsorption data were analysed by adsorption isothermal models. The adsorption isotherm is a functional parameter and one of the most useful for understanding the mechanism of adsorption that shows how the adsorbate molecules are distributed between the liquid phase and solid phase. These indicate the relationship between the amount of solute adsorbed per unit weight of the adsorbent and the concentration of an adsorbate in solution at a given temperature under equilibrium conditions. Among the many models proposed to explain adsorption equilibrium, the Langmuir, Freundlich and Dubinin-Radushkevich (D-R) adsorption isotherm models were used in this study to describe the equilibrium between adsorbed Pb<sup>2+</sup> ions on Fe<sub>3</sub>O<sub>4</sub>@GMA-AAm ( $q_e$ ) and Pb<sup>2+</sup> ions in solution ( $C_e$ ) at constant temperature.

The Langmuir model has been successfully applied in many adsorption processes and states that adsorption takes place at particular homogeneous sites into the adsorbent surface by monolayers with no transmigration of adsorbed ions on the plane of the surface. The Langmuir isotherm is described by the following equation:<sup>17</sup>

$$q_e = \frac{q_m K_L C_e}{1 + K_L C_e} \quad (6)$$

It can also be determined by transforming eqn (6) into linear form:

$$\frac{C_e}{q_e} = \frac{1}{K_L q_m} + \frac{C_e}{q_m} \quad (7)$$

where  $q_e$  represents the number of Pb<sup>2+</sup> ions adsorbed onto the adsorbent surface in equilibrium state (mg g<sup>-1</sup>);  $C_e$  is the equilibrium Pb<sup>2+</sup> ions concentration (mg L<sup>-1</sup>);  $q_m$  denotes the maximum adsorption capacity corresponding to complete monolayer coverage and  $K_L$  is the Langmuir adsorption equilibrium constant (L mg<sup>-1</sup>). When  $C_e/q_e$  is plotted against  $C_e$ , a straight line is obtained, so  $q_m$  and  $K_L$  values were defined respectively from the slope and the intercept of the linear plots. The results are presented in Fig. 15A.

**Fig. 15** Langmuir (A), Freundlich (B) and D-R (C) adsorption isotherms for Pb<sup>2+</sup> ions adsorption onto the magnetic adsorbent.

The amount of  $R_L$  factor indicates that the type of isotherm is irreversible ( $R_L = 0$ ), favourable ( $0 < R_L < 1$ ), linear ( $R_L = 1$ ) or unfavourable ( $R_L > 1$ ). The  $R_L$  is defined by the following equation:<sup>41</sup>

$$R_L = \frac{1}{1 + K_L C_0} \quad (8)$$

where  $C_0$  ( $\text{mg L}^{-1}$ ) is the initial concentration of  $\text{Pb}^{2+}$  ions. The  $R_L$  values in this study showed favourable adsorption between  $\text{Pb}^{2+}$  ions and adsorbent.

The Freundlich isotherm model is an experimental equation valid for multilayer adsorption on a heterogeneous adsorbent surface with a non-uniform distribution of adsorption heat. It is used to evaluation the adsorption intensity of the adsorbent to the adsorbate and it was assumed that at the first strong and quick adsorption occurs at binding sites, which depends on the ions concentration in the solution. The binding strength was decreased with the increasing of occupied site.<sup>37</sup> The Freundlich isotherm model is given by the following equation:

$$q_e = K_F C_e^{\frac{1}{n}} \quad (9)$$

The linear form can be expressed as follows:

$$\log q_e = \frac{1}{n} \log C_e + \log K_F \quad (10)$$

where  $K_F$  is the Freundlich constant indicating adsorption capacity;  $n$  is an experimental parameter related to the intensity of adsorption. The amount of heterogeneity of the adsorbent may change the value of  $n$  and for a favorable adsorption process the value of  $n$  should be in the range 1–10. The  $K_F$  and  $n$  can be calculated from the intercept and slope of linear plot of  $\ln q_e$  vs.  $\ln C_e$  respectively (Fig. 15B).

The Dubinin–Radushkevich isotherm is universally applied to represent the adsorption mechanism between physical and chemical adsorption onto a heterogeneous surface with a Gaussian energy distribution.<sup>42</sup> This adsorption model is represented by the following equation:

$$q_e = q_{\max} e^{-\beta \varepsilon^2} \quad (11)$$

The linear form of the D–R isotherm equation is:

$$\ln(q_e) = \ln(q_{\exp}) - \beta \varepsilon^2 \quad (12)$$

where  $\varepsilon$  is the activity coefficient related to mean adsorption energy ( $\text{mol}^2 \text{J}^{-2}$ );  $q_e$  is the amount of adsorbate in the adsorbent at equilibrium ( $\text{mg g}^{-1}$ );  $q_{\max}$  is the maximum adsorption capacity of  $\text{Pb}^{2+}$  ions on the adsorbent corresponding to D–R monolayer coverage ( $\text{mg g}^{-1}$ ). If  $\ln q_e$  is plotted against  $\varepsilon^2$ ,  $\beta$  and  $q_{\max}$  will be obtained from the slope and intercept respectively (Fig. 15C). The parameter  $\varepsilon$  is the Polanyi potential, which can be calculated as the following relation:

$$\varepsilon = RT \ln \left( 1 + \frac{1}{C_e} \right) \quad (13)$$

where  $R$  ( $8.314 \text{ J mol}^{-1} \text{ K}^{-1}$ ) is the gas constant and  $T$  (K) is the absolute temperature. The  $\beta$  gives the mean free energy  $E$  ( $\text{kJ mol}^{-1}$ ) of adsorption per molecule of adsorbate when it is transferred to the surface of the adsorbent from infinity in the solution and can be calculated using the following relationship:

$$E = \frac{1}{\sqrt{2\beta}} \quad (14)$$

The magnitude of this parameter is useful for information about the type of sorption process such as chemical ions exchange or physical sorption. When it lies between 8 and 16 ( $\text{kJ mol}^{-1}$ ), the adsorption occurs chemically. However, the reaction proceeds physically as it smaller than  $8 \text{ kJ mol}^{-1}$ .<sup>43</sup> It can be seen that the  $E$  value in this study is between 8 and 16 ( $\text{kJ mol}^{-1}$ ), indicating that the adsorption of  $\text{Pb}^{2+}$  ions may be interpreted as chemical ion exchange adsorption.

The Langmuir, Freundlich and D–R parameters for the adsorption of  $\text{Pb}^{2+}$  ions onto the magnetic adsorbent were summarized in Table 3. It was obvious that the Langmuir model fitted the experimental data better than the other models based on the  $R^2$  values in Table 3.

### 3.8. Effect of coexisting ions

Various toxic metal ions generally present in wastewater and the sample matrix may interfere in the removal efficiency of  $\text{Pb}^{2+}$  ions in media. The effects of coexisting cationic ions on the  $\text{Pb}^{2+}$  ions adsorption were studied and investigated in 50 mL solutions containing  $10 \text{ mg L}^{-1}$  of metal ions such as  $\text{Ag}^+$ ,  $\text{Fe}^{2+}$ ,  $\text{Cu}^{2+}$ ,

**Table 3** Parameters of isotherm models for adsorption of  $\text{Pb}^{2+}$  ions by adsorbent

Isotherms and linear equations	Parameters	$\text{Pb}^{2+}$ ions
Langmuir $\frac{C_e}{q_e} = \frac{1}{K_L q_m} + \frac{C_e}{q_m}$	$q_m$ ( $\text{mg g}^{-1}$ )	158.73
	$K_L$ ( $\text{L mg}^{-1}$ )	3.15
	$R_L$	0.03
	$R^2$	0.9984
Freundlich $\log q_e = \frac{1}{n} \log C_e + \log K_F$	$K_F$ ( $\text{mg g}^{-1}$ )	90.07
	$N$	4.06
	$R^2$	0.9264
	$q_{\max}$ ( $\text{mg g}^{-1}$ )	124.83
Dubinin–Radushkevich $\ln(q_e) = \ln(q_{\exp}) - \beta \varepsilon^2$	$E$ ( $\text{kJ mol}^{-1}$ )	8.45
	$\beta$ ( $\text{mol}^2 \text{kJ}^{-2}$ )	$7 \times 10^{-9}$
	$R^2$	0.9704

Fig. 16 Effect of coexisting cationic ions on the  $\text{Pb}^{2+}$  ions adsorption onto the magnetic adsorbent.

$\text{Zn}^{2+}$ ,  $\text{Cd}^{2+}$  ions. As seen in Fig. 16, the decreased number of  $\text{Pb}^{2+}$  ions in the presence of coexisting ions was lower than the decreased amount of  $\text{Pb}^{2+}$  ions in the absence of coexisting ions in solution. However, the results indicated that the adsorbent illustrated good selectivity for  $\text{Pb}^{2+}$  ions in the presence of coexisting ions. In general the competitive adsorption ability changes from one metal ion to another, which may be related to factors such as molecular mass, ion charges, hydrated ionic radius and hydration energy of the ionic metal.<sup>35</sup> Apparently the coexisting cations compete with  $\text{Pb}^{2+}$  ions for the active sites on the magnetic adsorbent. Therefore the number of active sites on the surface of the adsorbent was decreased for the adsorption of  $\text{Pb}^{2+}$  ions in solution.

### 3.9. Thermodynamic studies

The effect of various temperatures on the adsorption process was investigated to assess the spontaneity of the adsorption process. This provided valuable information about three thermodynamic parameters, Gibbs' free energy ( $\Delta G^\circ$ ), enthalpy

Fig. 17 Determination of thermodynamic parameters for the adsorption of  $\text{Pb}^{2+}$  ions onto the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite.

Table 4 Thermodynamic parameters of  $\text{Pb}^{2+}$  ions adsorption at different temperatures using nanocomposite

$T$ (K)	$K_{\text{eq}}$ ( $\text{mL g}^{-1}$ )	$\Delta G^\circ$ ( $\text{kJ mol}^{-1}$ )	$\Delta H^\circ$ ( $\text{kJ mol}^{-1}$ )	$\Delta S^\circ$ ( $\text{J mol}^{-1} \text{K}^{-1}$ )
283	111.9	−11.09	+50.786	+213.59
288	230.9	−13.03		
298	707.1	−16.25		
308	1013.14	−17.72		
318	1421.4	−19.19		

( $\Delta H^\circ$ ) and entropy ( $\Delta S^\circ$ ) that change during the adsorption. In order to obtain the thermodynamic of the adsorption process, 0.007 g of adsorbent was added into 50 mL of  $\text{Pb}^{2+}$  ion solution with an initial concentration of  $10 \text{ mg L}^{-1}$  at different temperatures (283, 288, 298, 308, and 318 K). The amounts of  $\Delta G^\circ$  can be determined by using the following equations.<sup>32</sup>

$$\Delta G^\circ = -RT \ln K_{\text{eq}} \quad (15)$$

$$K_{\text{eq}} = \frac{q_e}{C_e} \quad (16)$$

where  $R$  is the ideal gas constant ( $8.314 \text{ J mol}^{-1} \text{K}^{-1}$ ),  $T$  is the temperature (K) and  $K_{\text{eq}}$  is the adsorption equilibrium constant.  $K_{\text{eq}}$  can be calculated by eqn (16) and the enthalpy ( $\Delta H^\circ$ ) and the entropy ( $\Delta S^\circ$ ) can be determined from the van't Hoff equation<sup>44</sup> that shows the dependence of the equilibrium constant on the adsorption process on temperature as follows:

The van't Hoff equation (eqn (18)) is obtained by combining eqn (15) and (17) as follows:

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ \quad (17)$$

$$\ln k_{\text{eq}} = \frac{\Delta H^\circ}{R} \frac{1}{T} - \frac{\Delta S^\circ}{R} \quad (18)$$

The values of  $\Delta H^\circ$  and  $\Delta S^\circ$  were calculated from the slope and intercept of the van't Hoff plots of  $\ln(K_{\text{eq}})$  vs.  $1/T$  respectively, as presented in Fig. 17. The calculated thermodynamic parameters for the sorption of  $\text{Pb}^{2+}$  ions onto the  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  surface are reported in Table 4. As can be seen, the  $\Delta G^\circ$  at given temperatures was a negative value, confirming that the adsorption of  $\text{Pb}^{2+}$  ions onto the adsorbent was spontaneous and thermodynamically favourable adsorption had occurred. The positive value of  $\Delta H^\circ$  suggests that the interaction between  $\text{Pb}^{2+}$  ions and nanoadsorbent is endothermic in nature, while the positive value of  $\Delta S^\circ$  may be attributed to the increase of randomness in the solid/liquid interface during the adsorption process.<sup>45</sup> All the thermodynamic data indicated that the adsorption of  $\text{Pb}^{2+}$  ions onto  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  is favourable and can be used as an efficient adsorbent to remove  $\text{Pb}^{2+}$  ions from aqueous solution.

## 4. Conclusion

The  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  magnetic nanocomposite was successfully synthesized as a novel adsorbent for the efficient and fast

removal of  $\text{Pb}^{2+}$  ions from aqueous media. The TEM image showed the core-shell structure and the growth of the polymer chains on the surface of the nanoparticles could also be seen in the SEM and AFM images. The equilibrium time of  $\text{Pb}^{2+}$  ions adsorption was very short and obtained within 2 min. The kinetic models were applied to the experimental data. The adsorption was found to follow the pseudo-second-order model, and chemical adsorption was the rate controlling step of the adsorption. The isotherm analysis indicated that the adsorption of  $\text{Pb}^{2+}$  ions fitted the Langmuir equation well. The thermodynamic parameters showed that the adsorption process was spontaneous and endothermic in nature. As a result, our synthesized  $\text{Fe}_3\text{O}_4@\text{GMA-AAm}$  nanocomposite with suitable core-shell structure, easy separation method, high adsorption capacity and rapid adsorption rate ( $158.73 \text{ mg g}^{-1}$  and 2 min) may be a good magnetic adsorbent for the removal of  $\text{Pb}^{2+}$  ions from aqueous solutions, compared to some other reported nanocomposites based on  $\text{Fe}_3\text{O}_4$  (Table 1).
