## Six new coordination compounds based on rigid 5-(3-carboxy-phenyl)-pyridine-2-carboxylic acid: synthesis, structural variations and properties†

Jiang-Feng Song,<sup>\*a</sup> Ying-Ying Jia,<sup>a</sup> Rui-Sha Zhou,<sup>a</sup> Si-Zhe Li,<sup>a</sup> Xiao-Min Qiu<sup>a</sup> and Jie Liu<sup>\*b</sup>

Six new coordination compounds  $\text{Ni}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}$  (**1**),  $\text{Co}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}$  (**2**),  $\{\text{Cd}_2(\text{cppca})_2(\text{H}_2\text{O})_5\}_n$  (**3**),  $\{[\text{Cd}_3(\text{cppca})_2(\text{H}_2\text{P}_2\text{O}_7)(\text{H}_2\text{O})_6] \cdot 2\text{H}_2\text{O}\}_n$  (**4**),  $\{\text{Cu}(\text{Hcppca})_2\}_n$  (**5**) and  $\{[\text{Mn}_7(\text{cppca})_6(\text{Hcppca})_2(\text{H}_2\text{O})_{10}] \cdot 2\text{H}_2\text{O}\}_n$  (**6**) have been obtained by reactions of the corresponding metal salts and the rigid ligand 5-(3-carboxy-phenyl)-pyridine-2-carboxylic acid ( $\text{H}_2\text{cppca}$ ) under solvothermal conditions. All the compounds were fully characterized by single-crystal X-ray diffraction, elemental analysis, IR spectroscopy, thermal analysis and powder X-ray diffraction. The single-crystal X-ray analyses showed that compounds **1–6** have rich structural chemistry ranging from mononuclear (**1** and **2**), one-dimensional (**3** and **4**), two-dimensional (**5**) to three-dimensional (**6**) structures. Moreover, the framework of compound **6** may be simplified into a 3-nodal net with Schläfli symbol  $\{4^2 \cdot 6\}\{4^2 \cdot 8^2 \cdot 10^2\}\{4^3 \cdot 6^2 \cdot 8 \cdot 10^4\}_2$ , which shows an unprecedented (3,4,5)-connected topology net. The fluorescent properties of compounds **3** and **4** were investigated in the solid state and in various solvent emulsions, which indicated that compounds **3** and **4** are both highly sensitive fluorescent probes for the acetone molecules. Variable-temperature magnetic susceptibility measurements indicate weak antiferromagnetic interactions between metal centers in compounds **1**, **2**, **5** and **6**.

## Introduction

Coordination compounds have attracted considerable attention due to their intriguing structures<sup>1</sup> and wide potential applications in gas storage and separation,<sup>2</sup> luminescence,<sup>3</sup> molecular magnetism,<sup>4</sup> catalysis,<sup>5</sup> *etc.* Although lots of effort has been put into developing the ability to control the reactions, and significant progress has also been made, the controllable synthesis of coordination compounds with unique structure and function still remains a long-term challenge because their self-assembly processes are often influenced by compositional (chemical structure of ligands chosen, kind of metal salt, pH value, solvent system, metal-to-ligand ratio, *etc.*) and process parameters (reaction time, temperature, and pressure).<sup>6</sup>

As is well known, the selection and design of proper organic ligands have a large impact on the construction of coordination compounds with novel structures and unique properties. Among the chosen ligands, N-heterocyclic carboxylates have

been widely used to construct coordination compounds due to their multiplicity of coordinated atoms and wide range of binding modes resulting in good ligating ability to metal ions in various arrangements.<sup>7</sup> To date, diverse complexes based on N-heterocyclic carboxylates such as imidazole-carboxylic acid,<sup>8</sup> pyridine-carboxylic acid,<sup>9</sup> pyrimidine-carboxylic acid,<sup>10</sup> and so on, have been reported, which possess intriguing topology structures and specific functional characteristics. Here, the conjugated N-heterocyclic dicarboxylic ligand, 5-(3-carboxy-phenyl)-pyridine-2-carboxylic acid ( $\text{H}_2\text{cppca}$ ), is introduced as a rigid linker for the reasons as follows: (i) it possesses four carboxylic oxygen atoms and one pyridyl nitrogen atom, which can assume many kinds of bridging or chelating modes to meet the geometric coordination requirement of metal centers. (ii) The  $\text{H}_2\text{cppca}$  ligand might be partially or completely deprotonated at different pH values to adopt various acidity-dependent binding modes, on the other hand, it can act as hydrogen bond acceptors and donors to benefit the formation of various supramolecular structures.<sup>11</sup> (iii) The flexible C–C single bonds between phenyl and pyridyl rings can rotate freely, as results in the formation of *cis*- and *trans*-conformations and enrich structures of coordination compounds. (iv) The conjugated phenyl and pyridyl system of the  $\text{H}_2\text{cppca}$  ligand is helpful to provide remarkable luminescent performances and stable architecture.<sup>12</sup> Based on the above mentioned analysis, the  $\text{H}_2\text{cppca}$  ligand should be an effective component in the design of functional coordination complexes.

Herein, we describe the design and synthesis of six new coordination compounds based on  $\text{H}_2\text{cppca}$ ,  $\text{Ni}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}$  (1),  $\text{Co}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}$  (2),  $\{\text{Cd}_2(\text{cppca})_2(\text{H}_2\text{O})_5\}_n$  (3),  $\{[\text{Cd}_3(\text{cppca})_2(\text{H}_2\text{P}_2\text{O}_7)(\text{H}_2\text{O})_6] \cdot 2\text{H}_2\text{O}\}_n$  (4),  $\{\text{Cu}(\text{Hcppca})_2\}_n$  (5),  $\{[\text{Mn}_7(\text{cppca})_6(\text{Hcppca})_2(\text{H}_2\text{O})_{10}] \cdot 2\text{H}_2\text{O}\}_n$  (6). All the compounds were fully characterized by single-crystal X-ray diffraction, elemental analysis, IR spectroscopy, thermal analysis and powder X-ray diffraction. The fluorescence properties of compounds 3 and 4 in the solid state and in various solvent emulsions have also been investigated, displaying highly sensitive fluorescent probes for the acetone molecules. The magnetic properties of compounds 1, 2, 5 and 6 have been investigated.

## Experimental

### Materials and physical measurements

All reagents and solvents were commercially available and used as received without further purification. Elemental analysis (C, H, and N) was performed on a Perkin-Elmer 240C elemental analyzer. Infrared (IR) spectra were obtained with KBr Pellets on a Perkin Elmer Spectrum One FTIR spectrometer in the range of  $4000\text{--}400\text{ cm}^{-1}$  with the resolution ( $4.0\text{ cm}^{-1}$ ) and the scan's numbers.<sup>10</sup> Powder X-ray diffraction (PXRD) patterns of the samples were recorded by a RIGAKU-DMAX2500 X-ray diffractometer using  $\text{Cu-K}\alpha$  radiation ( $\lambda = 1.542\text{ \AA}$ ) with a scanning rate of  $10^\circ\text{ min}^{-1}$  and a step size of  $0.02^\circ$ . Thermogravimetric analysis (TGA) was performed on a Perkin-Elmer TGA-7000 thermogravimetric analyzer with a heating rate of  $10^\circ\text{ C min}^{-1}$ . The solvent emulsion and solid fluorescent spectra of compounds 3 and 4 were obtained on a HITACHI F-2700 fluorescence Spectrophotometer at room temperature. Variable-temperature magnetic susceptibility measurements were collected using SQUID magnetometer MPMS XL-7 (Quantum Design) at 1.0 kOe in the temperature range of 2–300 K.

### Synthesis of compounds 1–6

**Synthesis of  $\{\text{Ni}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}\}_n$  (1).** A mixture of  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol) and  $\text{H}_2\text{cppca}$  (0.05 mmol) was dissolved in a  $\text{DMF}/\text{H}_2\text{O}$  solution ( $v/v = 3 : 3$ , 6 mL), which was sealed in a 20 mL Teflon-lined stainless-steel reactor, heated at  $80^\circ\text{ C}$  for 72 h under autogenous pressure. After slowly cooling to room temperature, green stick crystals of compound 1 were collected by filtration and washed with distilled water several times. Yield: 60% (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{13}\text{H}_{19}\text{NNiO}_{10}$  (408): C, 38.24; H, 4.66; N, 3.43. Found: C, 38.25; H, 4.65; N, 3.45. IR data (KBr,  $\text{cm}^{-1}$ ): 3358(s), 3174(s), 1618(s), 1543(s), 1383(s), 1255(m), 881(m), 759(m).

**Synthesis of  $\{\text{Co}(\text{cppca})(\text{H}_2\text{O})_4 \cdot 2\text{H}_2\text{O}\}_n$  (2).** The procedure was the same as that for compound 1 except that  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol) was replaced by  $\text{Co}(\text{Ac})_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol). Pink acicular crystals of compound 2 were collected in 52% yield (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{13}\text{H}_{19}\text{CoNO}_{10}$  (408.22): C, 38.21; H, 4.65; N, 3.43. Found: C, 38.25; H, 4.65; N, 3.42. IR data (KBr,  $\text{cm}^{-1}$ ): 3358(s), 3174(s), 1618(s), 1543(s), 1383(s), 1255(m), 881(m), 759(m).

**Synthesis of  $\{\text{Cd}_2(\text{cppca})_2(\text{H}_2\text{O})_5\}_n$  (3).** The procedure was the same as that for compound 1 except that  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol) was replaced by  $\text{CdCl}_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol). Colorless crystals of compound 3 were collected in 55% yield (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{26}\text{H}_{24}\text{Cd}_2\text{N}_2\text{O}_{13}$  (797.31): C, 39.13; H, 3.01; N, 3.51. Found: C, 39.10; H, 3.03; N, 3.50. IR data (KBr,  $\text{cm}^{-1}$ ): 3417(s), 3174(s), 1626(m), 1556(s), 1391(s), 1028(m), 871(m), 771(m).

**Synthesis of  $\{[\text{Cd}_3(\text{cppca})_2(\text{H}_2\text{P}_2\text{O}_7)(\text{H}_2\text{O})_6] \cdot 2\text{H}_2\text{O}\}_n$  (4).** A mixture of  $\text{CdCl}_2 \cdot 6\text{H}_2\text{O}$  (0.1 mmol),  $\text{H}_2\text{cppca}$  (0.05 mmol) and  $\text{DMF}/\text{H}_2\text{O}/\text{MeOH}$  (3 : 1 : 3, 7 mL) was stirred in a 25 mL beaker for 5 minutes at room temperature. The above-mentioned mixtures, in which pyrophosphate aqueous solution (0.1 mL,  $0.1\text{ mol L}^{-1}$ ) was added, were transferred and sealed in a 20 mL Teflon-lined stainless steel reactor and kept under autogenous pressure at  $80^\circ\text{ C}$  for 72 h. After slowly cooling to room temperature, light-yellow block crystals were obtained and washed with distilled water. Yield: 43% (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{26}\text{H}_{32}\text{Cd}_3\text{N}_2\text{O}_{23}\text{P}_2$  (1139.68): C, 27.38; H, 2.81; N, 2.46. Found: C, 27.42; H, 2.79; N, 2.50. IR data (KBr,  $\text{cm}^{-1}$ ): 3408(s), 1608(m), 1548(s), 1399(s), 1092(s), 871(m), 771(m).

**Synthesis of  $\{\text{Cu}(\text{Hcppca})_2\}_n$  (5).**  $\text{H}_2\text{cppca}$  (0.05 mmol) and  $\text{CuCl}_2 \cdot 4\text{H}_2\text{O}$  (0.05 mmol) were mixed in  $\text{CH}_3\text{CN}/\text{H}_2\text{O}$  (4 : 4, 8 mL) solutions, and stirred for 0.5 h, then the mixture was transferred into a 20 mL Teflon-lined stainless steel container and heated at  $150^\circ\text{ C}$  for 72 h. After slowly cooling to room temperature, blue block crystals of compound 5 were isolated and washed with distilled water. Yield: 33% (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{26}\text{H}_{16}\text{CuN}_2\text{O}_8$  (547.95): C, 56.94; H, 2.92; N, 5.11. Found: C, 56.95; H, 2.90; N, 5.09. IR data (KBr,  $\text{cm}^{-1}$ ): 3438(m), 1684(s), 1612(s), 1377(m), 1249(m), 759(m).

**Synthesis of  $\{[\text{Mn}_7(\text{cppca})_6(\text{Hcppca})_2(\text{H}_2\text{O})_{10}] \cdot 2\text{H}_2\text{O}\}_n$  (6).** A mixture of  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$  (0.05 mmol),  $\text{H}_2\text{cppca}$  (0.05 mmol) and  $\text{CH}_3\text{CN}/\text{H}_2\text{O}$  (4 : 4, 8 mL) was stirred for 0.5 h to form a suspension where  $\text{NaOH}$  (0.1 M) was added to adjust pH = 6.0. Then the suspension was sealed in a 20 mL Teflon-lined stainless steel container and heated at  $120^\circ\text{ C}$  for 72 h. After slowly cooling to room temperature, light-yellow rod crystals of compound 6 were isolated after washed with water several times. Yield: 35% (based on the  $\text{H}_2\text{cppca}$ ). Elemental anal. calcd  $\text{C}_{104}\text{H}_{80}\text{N}_8\text{O}_{44}\text{Mn}_7$  (2530.34): C, 49.32; H, 3.16; N, 4.43. Found: C, 46.35; H, 3.12; N, 4.45. IR data (KBr,  $\text{cm}^{-1}$ ): 3438(m), 1626(m), 1556(s), 1385(s), 1191(m), 1028(m), 764(m).

### Single crystal structure determination

The crystal structures were determined by single-crystal X-ray diffraction. Reflection data were collected on a Bruker SMARTCCD area-detector diffractometer ( $\text{Mo-K}\alpha$  radiation, graphite monochromator) at room temperature with  $\omega$ -scan mode. Empirical adsorption correction was applied to all data using SADABS. The structure was solved by direct methods and refined by full-matrix least squares on  $F^2$  using SHELXTL 97 software.<sup>13</sup> Non-hydrogen atoms were refined anisotropically. All C-bound H atoms were refined using a riding model. All

calculations were carried out using SHELXTL 97. The crystallographic data and pertinent information for compounds 1–6 are contained in Table 1; selected bond lengths and angles are listed in Table S1.†

## Results and discussion

### Synthesis of compounds 1–6

Due to the rigid structure of the H<sub>2</sub>cpcpa ligand, the mixture of metal salt and organic ligand in different solvents usually produced lots of precipitations at room temperature, as makes the crystal complexes difficultly to be obtained, so compounds 1–6 were synthesized under the solvothermal conditions. DMF or acetonitrile is helpful to solve the H<sub>2</sub>cpcpa ligand, as provides a facility for the solvothermal reactions. The experimental results indicate that the reaction solvents and temperature play an important role in the preparation of compounds 1–6. Compounds 1–3 were obtained with high yield by the solvothermal reaction of metal ions and H<sub>2</sub>cpcpa in a DMF/H<sub>2</sub>O solution, however, DMF was substituted by the other organic solvents such as methanol, ethanol, acetonitrile, *etc.*, crystalline compounds 1–3 were difficult to be synthesized. Compound 4 has been obtained through adding pyrophosphoric acid methanol solution to DMF/H<sub>2</sub>O (3 : 3) solutions, methanol was crucial for the synthesis of compound 4, small crystals of compounds 4 were obtained if methanol was absent in the reaction. Notably, very small crystals of compounds 5 and 6 were obtained when the reaction solvent is DMF/H<sub>2</sub>O solutions, while DMF was substituted by CH<sub>3</sub>CN and further increased the reaction temperature, compounds 5 and 6 with larger crystals were obtained successfully, because high temperature and the pressure during the reaction process are helpful to improve the ligand solubility and enhance the reactivity of reactant.

**Crystal structures of [Ni(cppca)(H<sub>2</sub>O)<sub>4</sub>·2H<sub>2</sub>O]<sub>n</sub> (1) and [Co(cppca)(H<sub>2</sub>O)<sub>4</sub>·2H<sub>2</sub>O]<sub>n</sub> (2).** Compounds 1 and 2 with different molecular formula have the same crystal system, space group and isomorphic frameworks, so only the structure of compound 1 has been described in detail as a representative example. The single-crystal X-ray diffraction analysis reveals that compound 1 crystallizes in monoclinic space group *P*2<sub>1</sub>/*c*. As shown in Fig. 1a, compound 1 is a mononuclear complex in which the central Ni atom with a slightly distorted octahedral geometry receives contributions from five oxygens and one nitrogen belonging to one cppca<sup>2−</sup> anion and four water molecules. The cppca<sup>2−</sup> anion coordinates with Ni(II) in an N,O-chelating mode:  $\mu_1$ -κN,O (Fig. 2a). The Ni–N/O distances are in the range of 2.0375(18)–2.0946(18) Å, and the O/N–Ni–O/N bond angles range from 80.27(7) to 177.75(7)°.

Two Ni(H<sub>2</sub>O)<sub>4</sub> units constructed by the Ni center and four coordinated water are interconnected into a Ni<sub>2</sub>(H<sub>2</sub>O)<sub>8</sub> dimer

Fig. 1 (a) Coordination environment of the Ni(II) ion, the hydrogen atoms are omitted for clarity. (b) The 3D supramolecular network in compound 1.

Fig. 2 Coordination modes of the  $\text{H}_2\text{cppca}$  ligands in compounds 1–6.

with six-membered ring through  $\text{O1w-H}\cdots\text{O4w}$  hydrogen bonds (Fig. S1†). In  $\text{Ni}_2(\text{H}_2\text{O})_8$  dimer, coordinated  $\text{O1w}$  and  $\text{O4w}$  interact with lattice water molecules ( $\text{O5w}$  and  $\text{O6w}$ ) *via* hydrogen bonds, respectively; there are two hydrogen bonds between coordinated  $\text{O2w}$  and lattice water molecules ( $\text{O5w}$  and  $\text{O6w}$ ). The interactions between  $\text{Ni}_2(\text{H}_2\text{O})_8$  dimers and lattice water molecules ( $\text{O5w}$  and  $\text{O6w}$ ) result in the formation of a rather complex 2D supramolecular layer *via* hydrogen bonds, in which  $\text{O5w}$  and  $\text{O6w}$  bridge two dimers (Fig. S2†). The 2D supramolecular layers were joined into a 3D supramolecular network through  $\text{O-H}\cdots\text{O}$  hydrogen bonds between uncoordinated carboxyl group of  $\text{cppca}^{2-}$  anions and water molecules (Fig. 1b).

**Crystal structures of  $\{\text{Cd}_2(\text{cppca})_2(\text{H}_2\text{O})_5\}_n$  (3).** A single-crystal X-ray diffraction shows that compound 3 crystallizes in the triclinic space group  $P\bar{1}$ . The asymmetric unit of 3 contains two  $\text{Cd}^{2+}$  ions, two  $\text{cppca}^{2-}$  anions, and five coordination water molecules (Fig. 3a). The  $\text{Cd}_1$  center with a slightly distorted pentagonal bipyramid geometry where the equatorial plane comprises four carboxylate O atoms ( $\text{O2}$ ,  $\text{O5}$ ,  $\text{O3}^{\text{ii}}$  and  $\text{O4}^{\text{ii}}$ ) and

Fig. 3 (a) Coordination environment of the  $\text{Cd}(\text{II})$  ions. The hydrogen atoms are omitted for clarity. (b) The 1D chain constructed by Ring A and Ring B in compound 3.

one N atom ( $\text{N1}$ ) from three different  $\text{cppca}^{2-}$  anions, and two water molecules ( $\text{O1w}$  and  $\text{O2w}$ ) occupy the apical sites. Similar with  $\text{Cd}_1$ ,  $\text{Cd}_2$  is bound to six oxygens and one nitrogen from two independent  $\text{cppca}^{2-}$  anions and three water molecules. The  $\text{Cd-N/O}$  bond lengths are 2.275(3) and 2.434(3) Å, and the  $\text{O/N-Cd-O/N}$  bond angles range from 53.77(9) to 172.25(13)°.

In compound 3, two different coordination modes of  $\text{cppca}^{2-}$  anions are observed in the completely deprotonated  $\text{cppca}^{2-}$  ligands:  $\mu_2\text{-}\kappa\text{N,O}:\kappa\text{O}',\text{O}''$  (Fig. 2c) and  $\mu_3\text{-}\kappa\text{O}:\kappa\text{N,O}:\kappa\text{O}',\text{O}''$  (Fig. 2f). Two symmetry-related  $\text{Cd}_1$  metal centers are connected into a 18-membered ring by two  $\text{cppca}^{2-}$  ligands adopting  $\mu_2$  coordination modes (abbreviated to Ring A). Interestingly, another 18-membered ring is composed of two  $\text{Cd}_2$  centers and two  $\text{cppca}^{2-}$  ligands adopting  $\mu_3$  coordination modes (abbreviated to Ring B). Each Ring B joins two Ring A into an extended 1D chain *via*  $\text{Cd-O}$  bonds (Fig. 3b).

**Crystal structures of  $\{[\text{Cd}_3(\text{cppca})_2(\text{H}_2\text{P}_2\text{O}_7)(\text{H}_2\text{O})_6]\cdot 2\text{H}_2\text{O}\}_n$  (4).** A single-crystal X-ray diffraction shows that compound 4 crystallizes in the monoclinic space group  $C2/c$ . The asymmetric unit of 4 contains one and a half  $\text{Cd}^{2+}$  ions, one  $\text{cppca}^{2-}$  ligand, half a  $[\text{H}_2\text{P}_2\text{O}_7]^{2-}$  anion, three coordinated and one lattice water molecules. As depicted in Fig. 4a, both Cd centers in compound 4 are seven-coordinated and adopt a slightly distorted pentagonal bipyramid geometry. The  $\text{Cd}_1$  center coordinating with four carboxyl oxygen atoms ( $\text{O1}$ ,  $\text{O2}$ ,  $\text{O1}^{\text{i}}$  and  $\text{O2}^{\text{i}}$ ) from two different  $\text{cppca}^{2-}$  ligands and one oxygen atom ( $\text{O5}$ ) from  $[\text{H}_2\text{P}_2\text{O}_7]^{2-}$  anion in the equatorial positions, and two symmetry-related coordinated water molecules occupy the apical positions. While the  $\text{Cd}_2$  center is bound to six oxygens and one nitrogen from two independent  $\text{cppca}^{2-}$  anions, one coordinated  $[\text{H}_2\text{P}_2\text{O}_7]^{2-}$  anion and two water molecules. The  $\text{Cd-O/N}$  bond distances are in the range of 2.255(9)–2.458(6) Å and the  $\text{O/N-Cd-O/N}$  bond angles range from 54.3(2) to 178.9(4)°.

The  $\text{cppca}^{2-}$  adopting  $\mu_3\text{-}\kappa\text{N,O}:\kappa\text{O}',\text{O}'':\kappa\text{O},\text{O}'''$  coordination mode (Fig. 2g) and  $[\text{H}_2\text{P}_2\text{O}_7]^{2-}$  anions each connect two  $\text{Cd}_1$  and one  $\text{Cd}_2$  centers into a bent  $\text{Cd}_3$  secondary building units (SBUs). The  $\text{Cd}_3$  SBUs are further joined into a 1D chain by four  $\text{cppca}^{2-}$  anions, in which there exist in an 18-membered ring constructed by two  $\text{cppca}^{2-}$  ligands and two  $\text{Cd}_2$  centers (Fig. 4b).

Fig. 4 (a) Coordination environment of the  $\text{Cd}(\text{II})$  ions. The hydrogen atoms are omitted for clarity. (b) The 1D chain in compound 4.

**Crystal structures of  $\{\text{Cu}(\text{Hcppca})_2\}_n$  (5).** Compound 5 crystallizes in monoclinic space group  $P2_1/c$ . The asymmetric unit is composed of half a Cu(II) center and one partially deprotonated ( $\text{Hcppca}$ )<sup>−</sup> anion (Fig. 5a). The Cu center with a slightly distorted octahedral geometry where the basal plane occupied by two carboxylate O atoms (O4 and O4<sup>iii</sup>) and two N atoms (N1 and N1<sup>iii</sup>) from two chelating ( $\text{Hcppca}$ )<sup>−</sup> ligands, lies on a crystallographic inversion center, and the axes are occupied by two carboxylate oxygen atoms from another two ( $\text{Hcppca}$ )<sup>−</sup>. The Cu–O/N bond distances are in the range of 1.930(2)–2.564 Å, obviously, the Cu–O distances (2.564 Å) in axes are longer than that of the basal plane due to Jahn–Teller distortion. Each ( $\text{Hcppca}$ )<sup>−</sup> anion connects two Cu(II) ions to generate a 2D layer in  $\mu_2$ - $\kappa\text{N},\text{O}:\kappa\text{O}'$  coordination mode (Fig. 2d), in which 1D left- and right-handed helical chains with the Cu...Cu separation of 7.1846 Å alternately arrayed (Fig. 5b).

**Crystal structures of  $[\{\text{Mn}_7(\text{cppca})_6(\text{Hcppca})_2(\text{H}_2\text{O})_{10}\} \cdot 2\text{H}_2\text{O}]_n$  (6).** Compound 6 crystallizes in triclinic space group  $P\bar{1}$ . The asymmetric unit of compound 6 contains four crystallographically independent manganese(II) ion (Mn<sub>1</sub>, Mn<sub>2</sub>, Mn<sub>3</sub> and Mn<sub>4</sub>), three  $\text{cppca}^{2-}$  anions, one ( $\text{Hcppca}$ )<sup>−</sup> anion, five coordinated and one lattice water molecules (Fig. 6a). Mn<sub>1</sub> is six-coordinated with six oxygens from four  $\text{cppca}^{2-}$  anions and two water molecules, forming a distorted octahedral geometry. Mn<sub>2</sub> with octahedral geometry is bound to three carboxylate oxygens and two nitrogens from two independent  $\text{cppca}^{2-}$  and one ( $\text{Hcppca}$ )<sup>−</sup> anions and one oxygen from a water molecule, similar with Mn<sub>2</sub>, Mn<sub>4</sub> also coordinates with four oxygens and two nitrogens from three independent  $\text{cppca}^{2-}$  anions and one water molecule. While Mn<sub>3</sub> exhibits a slightly distorted trigonal bipyramidal geometry, which is bound to five oxygens from three different  $\text{cppca}^{2-}$  anions and two coordination water molecule. The Mn–O/N bond distances around Mn centers are in the range of 2.119(2)–2.284(3) Å, and the O/N–Mn–O/N bond angles range from 72.64(8) to 180.00(1)°.

Interestingly, there exist in four types of coordination modes for organic linker:  $\mu_1$ - $\kappa\text{N},\text{O}$ ;  $\mu_2$ - $\kappa\text{N},\text{O}:\kappa\text{O}'$ ;  $\mu_4$ - $\kappa\text{N},\text{O}:\kappa\text{O},\kappa\text{O}':\kappa\text{O}''$  and  $\mu_4$ - $\kappa\text{N},\text{O}:\kappa\text{O}':\kappa\text{O}'':\kappa\text{O}'''$  fashions (Fig. 2b, e, h, i). Mn<sub>2</sub>, Mn<sub>3</sub> and Mn<sub>4</sub> are assembled into a linear Mn<sub>3</sub> secondary building unit (SBU) by carboxyl groups from  $\text{cppca}^{2-}$  anions. The Mn<sub>3</sub>

Fig. 6 (a) The coordination environments of Mn(II) centers, (b) the 1D chain constructed by Mn<sub>3</sub> SBUs and  $\text{cppca}^{2-}$  anions, (c) the 2D layer constructed by 1D chains and  $\mu_2$ - $\text{cppca}^{2-}$  anions, (d) the 3D network in compound 6.

Fig. 5 (a) Coordination environment of the Cu(II) ion. The hydrogen atoms are omitted for clarity. (b) The 2D layer constructed by 1D left- and right-handed helical chains in compound 5.

SBUs are joined into a 1D chain by  $\text{cppca}^{2-}$  anions adopting  $\mu_4$ - $\kappa\text{N},\text{O}:\kappa\text{O},\kappa\text{O}':\kappa\text{O}''$  coordination mode, in which an 18-membered ring constructed by two  $\text{cppca}^{2-}$  ligands and two Mn centers (Fig. 6b). Then  $\text{cppca}^{2-}$  ligands adopting  $\mu_2$ - $\kappa\text{N},\text{O}:\kappa\text{O}'$  modes bridge Mn<sub>3</sub> and Mn<sub>4</sub> centers of the adjacent chains into a 2D corrugated layer with an irregular ring in which the two  $\text{Hcppca}^-$  ligands with  $\mu_1$ - $\kappa\text{N},\text{O}$  coordination mode are filled and coordinated with Mn<sub>2</sub> centers as the terminal chelators (Fig. 6c). The  $\text{cppca}^{2-}$  anions with  $\mu_4$ - $\kappa\text{N},\text{O}:\kappa\text{O}':\kappa\text{O}'':\kappa\text{O}'''$  modes in 2D corrugated layers joined Mn<sub>1</sub> ions to generate a 3D network (Fig. 6d). From the perspective of network topology,  $\text{cppca}^{2-}$  anions interacting with two Mn ions can be regarded as a line;

cpcpa<sup>2-</sup> anion with  $\mu_4$  coordination modes interacting with two  $Mn_3$  SBUs and  $Mn_1$  center is regarded as a 3-connected node, hexa-coordinated  $Mn_1$  center interacting four cpcpa<sup>2-</sup> ligands is also a 4-connected node; linear  $Mn_3$  SBU is considered as a 5-connected node. So the framework of compound **6** may be simplified into a 3-nodal net with Schlafli symbol  $\{4^2 \cdot 6\} \{4^2 \cdot 8^2 \cdot 10^2\} \{4^3 \cdot 6^2 \cdot 8 \cdot 10^4\}_2$ , which shows an unprecedented<sup>3-5</sup>-connected topology net determined by TOPOS (Fig. 7).

### Characterization

The experimental and simulated PXRD patterns of compounds **1–6** are shown in Fig. S3.† The simulated PXRD patterns from the single-crystal X-ray diffraction data are in agreement with the observed ones, indicating the phase purity of these synthesized crystalline products. The different intensities between the simulated and experimental patterns may be caused by the preferred orientation of the powder samples.

The FT-IR spectra of compounds **1–6** are displayed in Fig. 8. The wide peaks at  $3445\text{ cm}^{-1}$  in compounds **1–6** belong to the O–H stretching. The absorption peaks located at  $1605$  and  $1392\text{ cm}^{-1}$  can be ascribed to asymmetric and symmetric stretching vibrations of carboxylate groups, respectively. The peaks in the range of  $1257\text{--}1032\text{ cm}^{-1}$  can be ascribed to the in-plane bending vibration of C–H in the benzene ring, while the out-plane bending stretching vibrations appear in the range of

$762$  to  $694\text{ cm}^{-1}$ . Notably, the peak at  $1058\text{ cm}^{-1}$  for compound **4** corresponds to the stretching vibration of P–O bonds due to the present of  $[H_2P_2O_7]^{2-}$  anions.

### TG curves of compounds 1–6

The thermal behaviors of compounds **1–6** were studied from  $14\text{ }^\circ\text{C}$  to  $750\text{ }^\circ\text{C}$  under air (Fig. 9). The thermogravimetric analysis (TGA) curves of compounds **1–4** and **6** have similar thermal behavior with two-step weight loss. The first weight loss corresponded to the weight loss of water molecules (obsd 26.32% for **1**, 26.38% for **2**, 10.98% for **3**, 13.31% for **4**; 8.25% for **6**; calcd 26.49% for **1**, 26.45% for **2**, 11.29% for **3**, 12.64% for **4**, 8.43% for **6**). The second weight loss of **1–4** and **6** were characteristic of the combustion of organic ligands (obsd 55.11% for **1**, 54.94% for **2**, 56.46% for **3**, 43.43% for **4**, 72.05% for **6**; calcd 55.20% for **1**, 55.16% for **2**, 56.50% for **3**, 41.06% for **4**, 71.94% for **6**). The total weight loss of compounds **1–4** and **6** amounted to 81.61%, 81.56%, 67.44%, 56.74%, 80.30%, respectively, and the remaining weight correspond to the formation of NiO, CoO, CdO,  $Cd_3(PO_4)_2$ , MnO (obsd 18.57% for **1**, 18.68% for **2**, 32.56% for **3**; 43.26% for **4**, 19.70% for **6**; calcd 18.31% for **1**, 18.36% for **2**, 32.21% for **3**, 46.30% for **4**, 19.63% for **6**).

The framework of compound **5** is thermally stable up to  $300\text{ }^\circ\text{C}$ , on further heating, the  $(Hcpcpa)^-$  ligand begins to rapidly decompose, the total weight loss of compound **5** amounted to 84.95%, and the remaining weight is ascribed to the formation of CuO (obsd 15.05%, calcd 14.59%).

### Luminescence property

Under UV illumination,  $H_2cpcpa$  ligand can't give off light, however, compounds **3** and **4** exhibit strong blue light emission. The solid-state photoluminescence behavior of  $H_2cpcpa$ , compounds **3** and **4** were measured at room temperature (Fig. 10). They all exhibit strong blue light emission when excited at  $280\text{ nm}$ . The free  $H_2cpcpa$  and compound **3** exhibit emission bands at  $396\text{ nm}$  and  $375\text{ nm}$ , respectively, while

Fig. 7 The topology network of compound **6**.

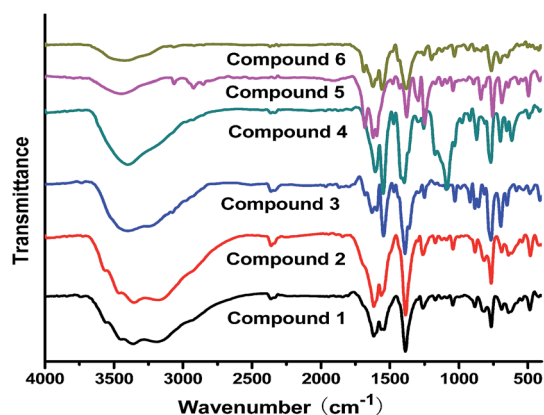

Fig. 8 The IR spectra of compounds **1–6**.

Fig. 9 The TGA curves of compounds **1–6**.

Fig. 10 Solid-state emission spectra of compounds **3** and **4** together with  $H_2cppca$ . Insets are the photo images of compounds **3** and **4** under daylight (Left) and UV illumination (Right) at 365 nm, respectively.

a blue emission band at 385 nm with a shoulder peak at 355 nm is observed in compound **4**. Compared with  $H_2cppca$ , the emission maximum of compounds **3** and **4** are slightly blue-shifted by 21 and 11 nm, respectively. So the emission bands of compounds **3** and **4** may be attributed to synergistic effects between intraligand charge transfer (LLCT) and ligand-to-metal transition (LMCT).<sup>14</sup> Notably, the fluorescence intensities of compounds **3** and **4** are apparently stronger than that of  $H_2cppca$  ligand under the same experimental conditions, which may be attributed to the unique coordination of ligand  $cppca^{2-}$  to the Cd(II) centers increasing the conformational rigidity, thereby reducing the non-radiative energy loss.<sup>15</sup>

The intense blue light emission of compounds **3** and **4** encouraged us to use them as hosts for the sensing of small molecules. The ground powders of compound **3** or **4** (0.5 mg) were immersed in water and common organic solvents 4.00 mL, methanol (MeOH), ethanol (EtOH), acetonitrile ( $CH_3CN$ ),  $N,N$ -dimethylformamide (DMF),  $N,N$ -dimethylacetamide (DMA), formaldehyde, cyclohexane, trichloromethane ( $CHCl_3$ ) and acetone, then treated by ultrasonication for 0.5 hours, and the corresponding PL spectra were measured as shown in Fig. 11a. The emission spectra of compounds **3** and **4** ( $\lambda_{ex} = 280$  nm) dispersed in different solvents revealed that the corresponding maximum emission peaks are largely dependent on the solvent molecules. For **3**, the emission peak with slightly shifted compared with its solid state emission spectrum ( $\lambda_{em} = 375$  nm), while the maximum emission peaks for **4** have a subtle blue-shifted by 9 nm compared with its solid state emission spectrum ( $\lambda_{em} = 385$  nm) (Fig. S4†). This phenomenon may be ascribed to the interactions between homogeneously dispersible framework and solvent molecules with different polarities.<sup>16</sup>

Notably, the fluorescent intensities of compounds **3** and **4** vary with the solvent molecules. The maximum luminescence intensity of 3-solvent emulsions gradually decreased in the order EtOH > MeOH >  $H_2O$  > DMA >  $CH_3CN$  >  $CHCl_3$  > formaldehyde > cyclohexane > DMF > acetone for **3**; while for **4**, the order is EtOH > DMA >  $CH_3CN$  > DMF > cyclohexane >  $CHCl_3$  >

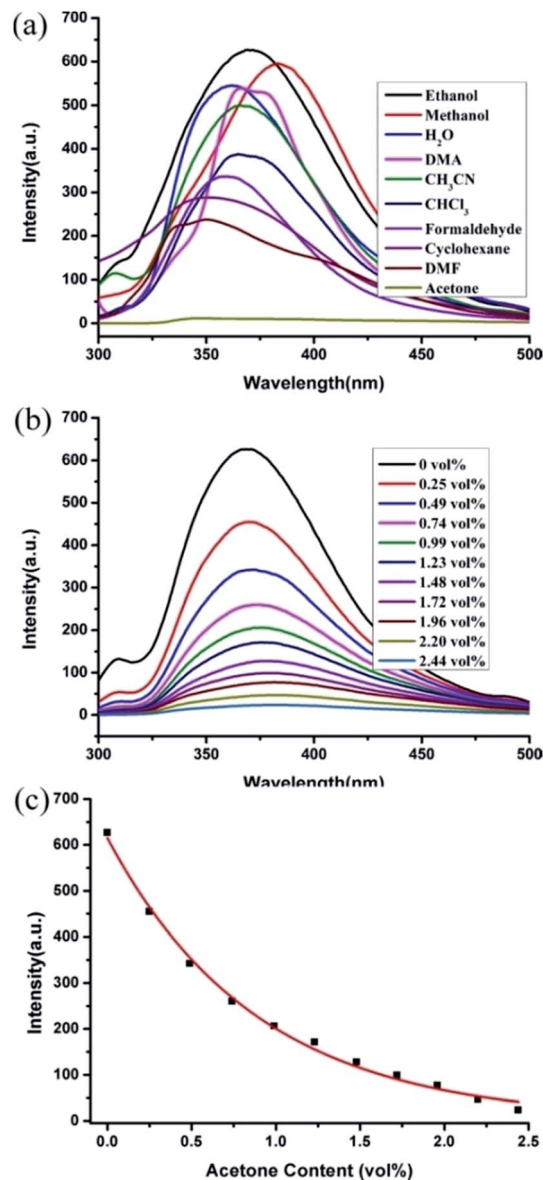

Fig. 11 (a) Emission spectra of compound **3** in different solvents when excited at 280 nm, (b) fluorescence titration of compound **3** dispersed in ethanol by gradual addition of acetone in ethanol, (c) the emission intensities of compound **3** in ethanol as a function of acetone content.

MeOH >  $H_2O$  > formaldehyde > acetone. Obviously, ethanol exhibits the most significant enhancing effect of fluorescence, while acetone exerted the significant quenching effect.

In addition, the sensing ability toward acetone for compounds **3** and **4** were further investigated. 0.5 mg samples of compounds **3** or **4** dispersed in ethanol were considered as the standard emulsion, and a batch of emulsions with gradually increased analytes concentration were prepared and monitored through fluorescent spectra. As seen in Fig. 11b, the fluorescence intensity of 3-ethanol emulsion has a significant decrease with the increasing concentration of acetone. The fluorescence quenching percentages (QP) can be calculated using equation:<sup>17</sup>

$$QP = (I_0 - I)/I_0 \times 100\%$$

where,  $I_0$  is the initial fluorescence intensity of the emulsion without the analyte, and  $I$  is the fluorescence intensity of the emulsion with the analyte. When the concentration of acetone increased to 0.49 vol%, the QP value is 45.38%, and the emission intensity was nearly disappeared with a QP of almost zero at an acetone content of 2.44 vol%. Similarly, compound **4** also features such highly sensitive and selective sensing for acetone molecules in ethanol solution (Fig. S4b†), meanwhile, 2.44 vol% acetone concentration also result in also exhibited a substantial quenching efficiency of **4**-ethonal emulsion (100%). Noticeably, the fluorescence decrease value was nearly proportional to the acetone concentration for **3** and **4**, which be well fitted with a first-order exponential decay (Fig. 11c and S4c†), indicating that the fluorescence quenching behavior for acetone of **3** or **4** is diffusion-controlled process.<sup>18</sup> The results reveal that compounds **3** and **4** could be promising luminescent probes for detecting acetone molecules.

In order to investigate the mechanism of quenching behavior by acetone, the UV-Vis spectra of acetone and the other solvents were measured (Fig. S5†). The results revealed that only acetone has a strong absorption ranging from 270 to 330 nm, while other solvents have no significant absorption in this range. Notably, the excitation wavelength of the compound **3** and **4** is 280 nm, which is completely overlaid by the absorbing band of acetone. Upon excitation at 280 nm, there is competition for the absorption of the light source energy between as-synthesized **3** and **4** and acetone molecules. So the efficient quenching of acetone in this system might be ascribed to the physical interaction of the solute and the solvent, which induces the changes in energy transfer.<sup>18b,19</sup>

### Magnetic properties of compounds **1**, **2**, **5** and **6**

Variable-temperature magnetic susceptibilities for compounds **1**, **2**, **5** and **6** were measured in the temperature range of 2–300 K under a 1000 Oe applied field. For compound **1**, the  $\chi_m T$  value is  $1.03 \text{ cm}^3 \text{ K mol}^{-1}$  at  $T = 300 \text{ K}$  (Fig. 12), which is close to the spin-only value of  $1.00 \text{ cm}^3 \text{ K mol}^{-1}$  for  $\text{Ni(II)}$  ( $S = 1$  and  $g = 2.0$ ). The  $\chi_m T$  of **1** slightly decreases with decreasing temperature and sharply reach a minimum ( $0.71 \text{ cm}^3 \text{ K mol}^{-1} \text{ K}$ ) at 2 K. In  $\chi_m^{-1}$  versus  $T$  curve, the magnetic susceptibilities data follow

Fig. 12 Plots of  $\chi_m T$  (black) and  $\chi_m^{-1}$  vs.  $T$  (blue) for compound **1**.

the Curie-Weiss law ( $\chi_m = C/(T - \theta)$ ) above 20 K with Curie constant  $C = 1.05 \text{ cm}^3 \text{ K mol}^{-1}$  and the Weiss constant  $\theta = -0.15 \text{ K}$ . According to the formulas  $C = 0.125g^2 \sum S(S+1)$ , the  $g$  value is 2.1 for **1**. For **2**, the  $\chi_m T$  value is  $2.16 \text{ cm}^3 \text{ K mol}^{-1} \text{ K}$  at  $T = 300 \text{ K}$  (Fig. 13), which is higher than the spin-only  $1.875 \text{ cm}^3 \text{ K mol}^{-1}$  for  $\text{Co(II)}$  ion ( $\text{Co(II)}$ ,  $S = 3/2$  and  $g = 2.0$ ). The  $\chi_m T$  continuously decreases with decreasing temperature and reach a minimum ( $1.34 \text{ cm}^3 \text{ K mol}^{-1} \text{ K}$ ) at 2 K. In  $\chi_m^{-1}$  versus  $T$  curve, the magnetic susceptibilities data follow the Curie-Weiss law ( $\chi_m = C/(T - \theta)$ ) above 30 K with Curie constant  $C = 2.27 \text{ cm}^3 \text{ K mol}^{-1}$  and the Weiss constant  $\theta = -5.80 \text{ K}$ . According to the formulas  $C = 0.125g^2 \sum S(S+1)$ , the  $g$  value is 2.18 for **2**. The negative value of  $\theta$  and the decrease of  $\chi_m T$  indicate weak antiferromagnetic interactions in compounds **1** and **2**.<sup>20</sup>

For compound **5** (Fig. 14), the  $\chi_m T$  value is  $0.389 \text{ cm}^3 \text{ K mol}^{-1} \text{ K}$  at  $T = 300 \text{ K}$ , which is higher than the spin-only value of  $0.375 \text{ cm}^3 \text{ K mol}^{-1}$  for  $\text{Cu(II)}$  ( $S = 1/2$  and  $g = 2.0$ ). Upon cooling, the  $\chi_m T$  continuously decreases with decreasing temperature and reach a minimum ( $0.79 \text{ cm}^3 \text{ K mol}^{-1} \text{ K}$ ) at 2 K. In  $\chi_m^{-1}$  versus  $T$  curve, the magnetic susceptibilities data follow the Curie-Weiss law ( $\chi_m = C/(T - \theta)$ ) above 50 K with Curie constant  $C = 1.98 \text{ cm}^3 \text{ K mol}^{-1}$  and the Weiss constant  $\theta = -8.11 \text{ K}$ . According to the formulas  $C = 0.125g^2 \sum S(S+1)$ , the  $g$  value is 2.14 for **5**. The negative value of  $\theta$  and the decrease of  $\chi_m T$  indicate weak antiferromagnetic interactions between  $\text{Cu(II)}$  centers in

Fig. 13 Plots of  $\chi_m T$  (black) and  $\chi_m^{-1}$  vs.  $T$  (blue) for compound **2**.

Fig. 14 Plots of  $\chi_m T$  (black) and  $\chi_m^{-1}$  vs.  $T$  (blue) for compound **5**.

Fig. 15 Plots of  $\chi_m T$  (black) and  $\chi_m^{-1}$  vs.  $T$  (blue) for compound 6.

compounds 5.<sup>21</sup> The field dependence of the magnetization for compound 5 at 2 K in the range of  $-70$ – $70$  kOe shows no hysteresis loop (Fig. S6†), which indicates no 3D magnetic ordering behavior exists even at 2 K. The experimental magnetization shows an abrupt increase to  $0.89$  N $\beta$  before 40 kOe and further steadily increases to  $1.03$  N $\beta$  at 70 kOe, which is close to the value for one uncoupled Cu<sup>II</sup> ion. This behavior further consist well with the result obtained from  $\chi_m T$  vs.  $T$  plot, indicating that there are very weak antiferromagnetic interactions between the Cu<sup>2+</sup> ions in compound 5.

The  $\chi_m T$  and  $\chi_m^{-1}$  vs.  $T$  plots for 6 are shown in Fig. 15, the  $\chi_m T$  value of Mn(II) ion at 300 K is  $4.26$  cm<sup>3</sup> K mol<sup>-1</sup>, which is close to the expected value ( $4.38$  cm<sup>3</sup> K mol<sup>-1</sup>) for magnetically non-interacting Mn(II) ions with  $S = 5/2$  and  $g = 2.0$ . Upon cooling,  $\chi_m T$  decreases smoothly to a minimum of  $0.69$  cm<sup>3</sup> K mol<sup>-1</sup> at 2 K, and the decrease of  $\chi_m T$  indicates a dominant antiferromagnetic interactions among the Mn(II) centers. In  $\chi_m^{-1}$  versus  $T$  curve, the magnetic behavior of compound 6 obeys the Curie–Weiss law ( $\chi_m = C/(T - \theta)$ ) in the temperature range of 2–300 K, and the corresponding Curie and Weiss constants are  $4.45$  cm<sup>3</sup> K mol<sup>-1</sup> and  $-13.43$  K ( $\theta$ ), respectively. According to the formulas  $C = 0.125g^2 \sum S(S + 1)$ , the  $g$  value is 2.02. The large negative  $\theta$  value further indicates significant antiferromagnetic interactions exist between neighboring Mn(II) ions.<sup>20,22</sup>

## Conclusion

In summary, six new coordination compounds based on H<sub>2</sub>cpcpa ligand have been synthesized and characterized in detail. Compounds 1–6 have rich structural chemistry ranging from mononuclear (1 and 2), one-dimensional (3 and 4), two-dimensional (5) to three-dimensional (6) structures. Moreover, the framework of compound 6 may be simplified into a 3-nodal net with Schläfli symbol  $\{4^2 \cdot 6\}\{4^2 \cdot 8^2 \cdot 10^2\}\{4^3 \cdot 6^2 \cdot 8 \cdot 10^4\}_2$ , which shows an unprecedented<sup>3-5</sup>-connected topology net. Compounds 3 and 4 show efficiently and easily recycled fluorescent probes for the acetone molecules. Weak antiferromagnetic interactions were observed in compounds 1, 2, 5 and 6. The further research for the construction of new coordination compounds based on H<sub>2</sub>cpcpa ligand is underway in our laboratory.
