Syntheses, structures, luminescent and photocatalytic properties of various polymers based on a "V"-shaped dicarboxylic acid†

Xiang-min Meng,^a Xia Zhang,^a Peng-fei Qi,^a Zi-ao Zong,^a Fan Jin^{*b} and Yu-hua Fan^{*a}

Solvothermal reactions of "V"-shaped 3,5-di(4'-carboxyl-phenyl)benzene acid (H₂dpb), and Cd(II)/Zn(II) salts in the presence of four ancillary bridging imidazole linkers afford four novel luminescent coordination polymers (LCPs), namely, {[Cd(dpb)₂(bimb)₂]·0.5H₂O}_n (1), [Cd(dpb)(tib)]_n (2), [Zn(Hdpb)₂(4,4'-bibp)]_n (3) and [Cd(dpb)(1,3-bitl)]_n (4), (bimb = 1,4-bis(imidazol-1-ylmethyl)benzene, tib = 1,3,5-tris(1-imidazolyl)benzene, 4,4'-bibp = 4,4'-bis(imidazol-1-yl)biphenyl and 1,3-bitl = 1,3-bis(1-imidazolyl)toluene). Then complexes 1–4 are characterized by elemental analysis, IR spectroscopy, powder X-ray diffraction (PXRD), thermogravimetric (TG) analysis and single-crystal X-ray diffraction. Single-crystal X-ray diffraction analysis shows that complex 1 shows an unprecedented 3-nodal (2,2,4)-connected 2D + 2D → 3D two-fold interpenetration framework with the Schläfli symbol (12⁵.16)(12)². Complexes 2 and 3 show a 2D layer structure and 1D zigzag chain, which are further assembled into a 3D supramolecular structure by π···π interactions and H-bonds, respectively. While complex 4 displays a 3-nodal (2,2,8)-connected network with a –ABAB– fashion. The luminescent recognition properties of polymers 1–4 to metal cations and anions have also been explored systematically. The results demonstrate that 2 and 3 display highly sensitive and selective luminescence sensing towards Fe³⁺ ions, and 4 displays highly sensitive and selective luminescence sensing towards Cu²⁺ ions. 1–4 can work as highly sensitive sensors to Cr₂O₇²⁻ by luminescence quenching. Moreover, the photocatalytic properties of four Cd(II)/Zn(II) compounds (complex 1–4) have also been investigated.

Introduction

During the past decades, the construction of luminescent coordination polymers (LCPs) has attracted considerable attention not only for their potential applications in luminescence,¹ catalysis,² magnetism,³ gas storage,⁴ separation,⁵ proton conduction,⁶ nonlinear optics⁷ and so on, but also for their aesthetically pleasing structures and diversities in topology.⁸ In particular, based on their great physical and chemical characteristics, their capability of detecting heavy metal ions plays a significant role in public health,⁹ environmental protection¹⁰ and medicinal science.¹¹ For example, Wang's group has reported that Cd-based LCPs were assembled using aromatic hexa-carboxylate which shows high sensitivity to Fe³⁺ ions in waste-water.¹² The Eu-MOF reported by Zhu's group can detect

Cu²⁺ ions.¹³ Liu synthesized a NH₂-Zn-MOF that can detect Cr(III) and Cr(IV) which could cause water pollution.¹⁴ Meanwhile, the photocatalytic capability of the Zn/Cd-based CPs which are constructed using V-shaped ligands, has received wide attention from the viewpoint of chemists.¹⁵ However, the LCPs sensors for detecting metal ions which assemble using V-shaped ligands are still quite few.

As we known, the aromatic multicarboxylate ligands play an important role in tuning the coordination framework structures due to their abundant coordination modes. Furthermore, due to their bent backbones and versatile bridging fashions, V-shaped aromatic multicarboxylate ligands are excellent candidates for building highly connected, interpenetrating, or helical coordination frameworks.^{16,17} Compared with some other reported V-shaped ligands (4-bpah,^{15a} 4-bpab^{15b} and 2,4'-bpdc^{17b}), the V-shaped H₂dpb we selected could show more advantages: (1) the H₂dpb ligand with high solubility is easy to synthesize; (2) the suitable size makes it a reasonable candidate to generate LCPs with open frameworks; (3) the reports on LCPs assembled by V-shaped aromatic multicarboxylate ligands are rare; (4) the free rotation of two carboxylic benzene ring can promote the flexibility of the H₂dpb ligand to meet the requirements of coordination geometries of metal ions; (5) the carboxylic group could show more coordination modes while coordinating to

Scheme 2 Various polymeric structures of complexes 1–4.

metal ions. Meanwhile, to further investigate the influence of auxiliary N-donor ligands on the formation of final architectures, a series of semi-rigid/rigid imidazole ligands with different conformations were introduced into the system (Scheme 1).

Herein, four mixed-ligand LCPs have been successfully synthesized under solvothermal conditions, namely, $\{[\text{Cd}(\text{dpb})_2(\text{bimb})_2] \cdot 0.5\text{H}_2\text{O}\}_n$ (1), $[\text{Cd}(\text{dpb})(\text{tib})]_n$ (2), $[\text{Zn}(\text{Hdpb})_2(4,4'\text{-bibp})]_n$ (3) and $[\text{Cd}(\text{dpb})(1,3\text{-bitl})]_n$ (4), which show a systematic variation of architectures from 1D chain based on supramolecular to 3D interpenetrated framework (Scheme 2). The packing structures of these four complexes show that the nature of the bridging N-donor linkers has a significant effect on the H₂dpb coordination modes. Moreover, the luminescent recognition properties of metal cations/anions and photocatalytic activities of the four Cd(II)/Zn(II) compounds were also investigated.

Experimental section

Materials and physical measurements

All reagents and solvents were purchased from Jinan Henghua Sci. & Tec. Co. Ltd. and were used without further purification.

Infrared spectrum was recorded as KBr pellets on the Nicolet 170SX spectrometer in the 4000–400 cm⁻¹ region. Elemental analysis (C, H, and N) was performed in a model 2400 Perkin-Elmer analyzer. Thermogravimetric analyses (TGA) were measured on a Perkin-Elmer TGA-7 thermogravimetric analyzer under air conditions from room temperature to 800 °C with a heating rate of 10 °C min⁻¹. The X-ray powder diffractions (XRPD) were collected on an Enraf-Nonius CAD-4 X-ray single-crystal diffractometer with Cu-K α radiation. Topological analysis were performed and confirmed by the Topos program and the Systre software.^{18,19}

Synthesis of $\{[\text{Cd}(\text{dpb})_2(\text{bimb})_2] \cdot 0.5\text{H}_2\text{O}\}_n$ (1)

A mixture of H₂dpb (0.20 mmol, 0.064 g), bimb (0.20 mmol, 0.048 g), Cd(NO₃)₂·4H₂O (0.20 mmol, 0.062 g) and 8 mL of DMF–H₂O (v/v = 1 : 1) were placed in a Teflon-lined stainless steel vessel, heated to 120 °C for 3 days, and then cooled (a descent rate of 5 °C h⁻¹) to room temperature. Colourless block crystals of 1 were obtained. Yield of 51% (based on Cd). Anal. (%) calcd. for C₃₄H₂₆CdN₄O_{4.5}: C, 60.41; H, 4.03; N, 8.29. Found: C, 60.31; H, 3.91; N, 8.31. IR (KBr pellet, cm⁻¹): 3588 (m), 3170 (m), 1625 (s), 1550 (m), 1370 (vs), 1100 (m), 855 (m), 791 (m) 659 (w).

Synthesis of $[\text{Cd}(\text{dpb})(\text{tib})]_n$ (2)

A mixture of H₂dpb (0.20 mmol, 0.064 g), tib (0.20 mmol, 0.056 g), Cd(NO₃)₂·4H₂O (0.20 mmol, 0.062 g), NaOH (0.40 mmol, 0.016 g) and 8 mL of water was placed in a Teflon-lined stainless steel vessel, heated to 150 °C for 3 days, and then cooled (a descent rate of 5 °C h⁻¹) to room temperature. Colourless block crystals of 2 were obtained. Yield of 60% (based on Cd). Anal. (%) calcd. for C₃₅H₂₄CdN₆O₄: C, 59.63; H, 3.43; N, 11.92. Found: C, 59.51; H, 3.32; N, 11.64. IR (KBr pellet, cm⁻¹): 3126 (s), 1653 (m), 1506 (s), 1401 (vs), 1244 (m), 775 (m), 669 (m).

Synthesis of $[\text{Zn}(\text{Hdpb})_2(4,4'\text{-bibp})]_n$ (3)

Complex 3 was synthesized following the same synthetic procedure as that for complex 2 except that 4,4'-bibp was used instead of tib and Cd(NO₃)₂·4H₂O was instead by Zn(NO₃)₂·6H₂O. Pink block crystals of 3 were obtained. Yield of 51% (based on Zn). Anal. (%) calcd. for C₅₈H₄₀ZnN₄O₈: C, 70.62; H, 4.09; N, 5.68. Found: C, 70.46; H, 4.02; N, 5.56. IR (KBr pellet, cm⁻¹): 3146 (m), 1721 (s), 1608 (s), 1554 (s), 1405 (vs), 1310 (m), 824 (m), 774 (s).

Synthesis of $[\text{Cd}(\text{dpb})(1,3\text{-bitl})]_n$ (4)

Complex 4 was synthesized following the same synthetic procedure as that for complex 1 except that 1,3-bitl was used instead of bimb. Colourless block crystals of 4 were obtained. Yield of 48% (based on Cd). Anal. (%) calcd. for C₃₃H₂₄CdN₄O₄: C, 60.70; H, 3.70; N, 8.58. Found: C, 60.56; H, 3.62; N, 8.55. IR (KBr pellet, cm⁻¹): 3125 (s), 1590 (m), 1506 (s), 1398 (vs), 1247 (w), 859 (m), 771 (m).

X-ray crystallography

X-ray crystallography data of complexes 1–4 were collected on a Bruker Apex Smart CCD diffractometer at 293(2) K with graphite-monochromatized Mo-K α radiation ($\lambda = 0.71073$ Å) by using the ω -2 θ scan mode. The structure was solved by direct methods using SHELXS-97.²⁰ The non-hydrogen atoms were defined by the Fourier synthesis method. Positional and thermal parameters were refined by the full matrix least-squares method (on *F*²) to convergence.²¹ Crystallographic data for complexes 1–4 are given in Table 1. Selected bond lengths and angles for 1–4 are listed in Table S1.† CCDC numbers for complexes of 1–4 are 1430347 for 1, 1402587 for 2, 1061113 for 3 and 1479858 for 4.

Results and discussion

Synthesis and characterization

The crystals of complexes 1–4 is dependent on the experimental method and the nitrate salts of Cd(NO₃)₂·4H₂O and Zn(NO₃)₂·6H₂O. Then suitable crystal were characterized by single-crystal X-ray diffraction after cooling to room temperature. Those complexes 1–4 are stable in the solid state even after extended exposure to air. Meanwhile, all of the complexes 1–4 have poor solubility in water and common organic solvent, but can be slightly soluble in very high polarity solvents.

The IR spectra of complexes 1–4 display characteristic absorption bands of the coordinated carboxylate groups appear at 1590–1653 cm⁻¹ for asymmetric stretching and 1320–1401 cm⁻¹ for the symmetric.²² Meanwhile, a adsorption bands are observed in *ca.* 1721 cm⁻¹,²³ suggesting the partially

deprotonation of carboxylic groups in 3, which is consistent with the results of the X-ray diffraction analysis.

Structure description of {[Cd(dpb)₂(bimb)₂]·0.5H₂O}_n (1)

Single-crystal X-ray diffraction analysis reveals that 1 crystallizes in the orthorhombic system with space group *I*2(1)2(1)2(1). As can be seen from Fig. 1a, the asymmetric unit consists of one Cd(II) ion, two dpb²⁻ carboxylate ligands and two bimb N-donor ligands. The Cd(II) is six-coordinated by four O atoms from two dpb²⁻ ligands [Cd(1)–O(1)=Cd(1)–O(1)^{#1} = 2.248(5) Å, Cd(1)–O(2)=Cd(1)–O(2)^{#1} = 2.545(6) Å] and two N atoms from two bimb bridging linkers [Cd(1)–N(2)=Cd(1)–N(2)^{#1} = 2.283(5) Å], which adopts a distorted octahedral {CdN₂O₄} coordination geometry.

As shown in Scheme 3, each “V”-shaped dpb²⁻ ligand coordinates with two adjacent Cd(II) ion by adopting a μ_2 -(κ^1 - κ^1)-(κ^1 - κ^1) coordination mode (Scheme 3, Mode I) forming an infinite 1D [Cd-dpb]_n linear chain, in which the two carboxyl groups show same μ_1 -(κ^1 - κ^1) coordination. Interestingly, the μ_2 -bridging bimb ligands exhibits a “U” shape conformation to connect the adjacent Cd(II) ions to result in a single-strand helix chain [Cd-bimb]_n with the Cd⋯Cd separation of 12.86 Å. The two types of 1D chains ([Cd-dpb]_n and [Cd-bimb]_n) are alternatively connected with each other, constructing a 2D network (Fig. 1b). The two adjacent 2D networks are further interact with each other through helix chain ([Cd-bimb]_n) twining round the “V”-shaped H₂dpb ligands, finally resulting in a rarely 2D + 2D → 3D two-fold interpenetration parallel framework (Fig. 1c). The effective free volume of 1 was 10.5% of the crystal volume

Fig. 1 (a) Coordination environment of the Cd(II) ion in complex 1 (symmetry codes: (A) $-x + 3/2, y + 0, -z + 1$; (B) $-x + 1/2, y + 0, -z + 2$; (C) $x, -y + 2, -z + 1/2$). (b) View of the 1D [Cd-dpb]_n linear chain, 1D [Cd-bimb]_n helical chain and 2D network of 1 (blue spheres: bimb ligands; red spheres: dpb²⁻ ligands). (c) The 2D + 2D → 3D two-fold interpenetration parallel networks viewed along the *a* axis. (d) The 2D + 2D → 3D interpenetrated (2,2,4)-connected topology (12⁵ · 16)(12)² sheets in 1.

Scheme 3 Diverse coordination modes of H₂dpb in complexes 1–4.

(318.7 out of the 3035.7 Å³ unit cell volumes), calculated by PLATON analysis.²⁴

From the viewpoint of structural topology, the Cd(II) ions are coordinated by two dpb²⁻ ligands and two bimb ligands, which can be viewed as a 4-connected node and the dpb²⁻ ligand as a “V”-shaped spacer, then an unprecedented 3-nodal (2,2,4)-connected 3D interpenetrated framework is created with (12⁵ · 16)(12)² topology (Fig. 1d).

Structure description of [Cd(dpbb)(tib)]_n (2)

The crystal structure determined by single-crystal X-ray diffraction showed that complex 2 crystallizes in the monoclinic system, space group *P2₁/c*. The asymmetric unit of 2 contains one Cd(II) cation, one dpb²⁻ ligand and one tib ligand. As shown in Fig. 2a, each Cd(II) cation with an unusual {CdN₃O₄} distorted decahedral coordination geometry is seven-coordinated by three imidazolyl nitrogen atoms from three tib ligands [Cd–O = 2.320(3)–2.580(4) Å], and four oxygen atoms from two dpb²⁻ anions [Cd(1)–N(2) = 2.322(4) Å, Cd(1)–N(4)^{#1} = 2.306(4) Å and Cd(1)–N(5) = 2.326(4) Å]. Cd to O/N distances and bond angles are within the normal range.

In complex 2, the completely deprotonated dpb²⁻ ligand exhibits a μ₂-(κ¹-κ¹)-(κ¹-κ¹) coordination mode (Scheme 3, Mode I). Two neighbour Cd(II) cation were connected by “V”-shaped dpb²⁻ ligand form a 1D [Cd-dpb]_n chain with the Cd···Cd separation is 17.625 Å, and tib ligand form a 1D [Cd-tib]_n ladder shaped chain with different Cd···Cd separation (10.573, 11.411 and 13.682 Å), respectively. Each ladder-like chain contains two types of binuclear ({Cd₂N₈C₁₀}) 20-membered ring and {Cd₂N₈C₁₂} 22-membered ring loops. The adjacent 1D chains are further intersected with each other by sharing the same Cd(II) cation, finally giving a 2D network (Fig. 2b). The final 3D supramolecular framework of complex 2 is through the C–H···C between the carbon atoms from phenyl ring and imidazolyl [C(35′)–H(35′)···C(6) = 2.915 Å] (Fig. 2c and S1†). Meanwhile, π···π stacking interactions make a more stable 3D supramolecular structure. Besides, the void volume of 2 is 44.3% of the crystal volume (2489.9 out of the 5621.9 Å³ unit cell volume), calculated by PLATON.

From the viewpoint of topology, the “V”-liked dpb²⁻ anions can be defined as 2-connected nodes, while the tib ligands can be considered as 3-connected nodes. Thus the 3D

Fig. 2 (a) Coordination environment of the Cd(II) ion in complex 2 (symmetry codes: (A) $-x + 1, -y + 1, -z + 2$; (B) $x, y - 1, z$; (C) $x, y + 1, z$). Note: the dangling benzyl rings are omitted for clarity. (b) View of the 2D network of 2 (blue spheres: tib ligands; green spheres: dpb^{2-} ligands). (c) The 2D \rightarrow 3D supramolecular networks by C–H \cdots C and π – π interactions. (d) Views of the (2,3,5)-connected 3D supramolecular frameworks with unprecedented $(4^2 \cdot 6 \cdot 8^6 \cdot 12)(4^2 \cdot 6)(8)$ topology.

supramolecular structure can be simplified as an unprecedented 3-nodal (2,3,5)-connected framework with the point Schläfli symbol $(4^2 \cdot 6 \cdot 8^6 \cdot 12)(4^2 \cdot 6)(8)$ (Fig. 2d).

Structure description of $[\text{Zn}(\text{Hdpb})_2(4,4'\text{-bibp})]_n$ (3)

A similar reaction environment compared with complex 1 was used except for the H_2O – CH_3CN system being replaced with the H_2O , results in a 3D supramolecular structure. Complex 3 crystallizes in monoclinic space group $C2/c$. The asymmetric unit of 3 contains one Zn(II) ion, two Hdpb^- carboxylate ligands, and one 4,4'-bibp N-donor ligand as shown in Fig. 3a. The Zn(II) center is a four-coordinated by two O atoms from two Hdpb^- ligands and two N atoms from two 4,4'-bibp ligands, displaying a distorted triangle cone geometry. The bond length of Zn–O is 1.940(2) Å, and the Zn–N distance is 2.019(2) Å, respectively. Both Zn–O and Zn–N bond length also well-matched to similar complexes.²⁵

The two partially deprotonated carboxyl groups of “V”-liked Hdpb^- ligands exhibit a μ_1 –(κ^1 – κ^0) coordination mode (Scheme 3, Mode II). Two adjacent “V”-liked Hdpb^- ligands linked the same Zn(II) ions hold a limited helix chain, and the N-donor ligands linking two adjacent Zn(II) ions along the axis to form a 1D zigzag chain $[\text{Zn}(\text{bibp})]_n$ (Fig. 3b). Such chains are linked through O–H \cdots O hydrogen bonds along [1,1,0] orientation to form 3D cone supramolecular structure (Fig. 3c and $S2^\dagger$). The dihedral angle between the three phenyl rings in Hdpb^- are 18.78(4)°, 34.31(3)° and 47.91(4)° respectively.

Structure description of $[\text{Cd}(\text{dpb})(1,3\text{-bitl})]_n$ (4)

A similar reaction environment compared with complex 3 was used except for the bimb N-donor ligand being replaced by 1,3-bitl, results in another 3D supramolecular ladder structure. Compound 4 crystallizes in the monoclinic space group $P2_1/c$. In the asymmetric unit, there exist one crystallographically unique Cd(II) ions, one dpb^{2-} carboxylate ligands and one coordinated 1,3-bitl N-donor ligand. As shown in Fig. 4a, each Cd(II) cation also show an unusual seven-coordinated by five O atoms from three individual dpb^{2-} carboxylate ligands (Cd–O = 2.316(6)–2.622(6) Å) and two N atoms from two different 1,3-bitl N-donor ligand (Cd–N(2) = 2.231(7) and Cd–N(3) = 2.314(8) Å) with a $\{\text{CdN}_2\text{O}_5\}$ coordination environment, displaying a slightly distorted decahedral geometry. Both Cd–O and Cd–N bond length also well-matched to similar complexes.²⁶

In complex 4, the completely deprotonated dpb^{2-} ligand exhibits a μ_3 –(κ^1 – κ^2)–(κ^1 – κ^1) coordination mode (Scheme 3, Mode III). The dihedral angles between the three phenyl rings in dpb^{2-} are 35.78(2), 27.96(3) and 19.18(3)°, respectively. In the structure, two Cd(II) ions are connected by the μ_2 –(κ^1 – κ^2) carboxyl group, forming $\{\text{Cd}_2(\text{COO})_2\}$ SBUs, which can be viewed as a shared nodal. Meanwhile, the two adjacent $\{\text{Cd}_2(\text{COO})_2\}$ SBUs are connected by two “V”-shaped dpb^{2-} ligands forming a bigger $\{\text{Cd}_4(\text{dpb}^{2-})_2\}$ (28-membered) ring and two bitl ligands forming a $\{\text{Cd}_4(\text{bitl})_2(\text{COO})_2\}$ (26-membered) ring. Then the two different loops intersected with each other forming a stable 2D network with a $17.776(15) \times 13.668(12) \times 6.1052(28)$ Å³ quadrilateral opening (Fig. 4b). The adjacent 2D

Note: the dangling benzyl rings are omitted for clarity. (b) View of the 2D network of 4 (blue spheres: 1,3-bis(1-imidazolyl)propane ligands; red spheres: dppb^{2-} ligands). Note: the dangling benzyl rings are omitted for clarity. (c) From 2D network to 3D framework of complex 4, which are linked by C–H \cdots O bonds along [0,1,1] orientation. Note: the dangling benzyl rings are omitted for clarity. (d) Views of the (2,2,8)-connected 2D \rightarrow 3D network with a –ABAB– fashion.

network are alternatively connected with each other through C–H \cdots O bonds (Table S2,† C(28)–H(28) \cdots O(3) = 2.411 and C(21)–H(21) \cdots O(3) = 2.431 Å), constructing a stable 3D network (Fig. 4c and S3†). The effective free volume of 4 was 22.9% of the crystal volume (823.0 out of the 3600.8 Å³ unit cell volumes), calculated by PLATON analysis.

From the topologically, the $\{\text{Cd}_2(\text{COO})_2\}$ SBUs can be regarded as eight-connected nodes and “V”-shaped dppb^{2-} ligands as two-connected nodes; thus, this layer displays a 3-nodal (2,2,8)-connected network (Fig. 4d).

Structural comparison and discussion

The structures of LCPs have been found to be greatly influenced by N-donor ligands based on previous literature. As shown in Scheme 3 and Table S3,† H_2dppb exhibits versatile coordination modes, resulting in different new structures (1D–3D). In complexes 1 and 2, the “V”-shaped dppb^{2-} ligands chelate the metal atoms (chelate both in 1 and 2) through their two carboxylate groups, to further stabilize the 1D chain. After that, those chains further interacted with bimb (1D $[\text{Cd-bimb}]_n$ helix chain)/tib (1D $[\text{Cd-tib}]_n$ ladder chain) chain to form the final 2D + 2D \rightarrow 3D interpenetrated (2,2,4)-connected unprecedented and (2,3,5)-connected unprecedented 3D/2D topologies. For complex 3, only one carboxylate group of the H_2dppb ligand coordinated with the metal atoms (monodentate in 3), and the other carboxylate group interacted with the adjacent $[\text{Zn}(\text{Hdppb})_2(4,4'\text{-bibp})]_n$ chain to form the 3D supramolecular structure through H-bonding interactions. For 4, one carboxylate group of the dppb^{2-} adopt in μ_2 -(κ^1 - κ^2)-chelate fashion and the other carboxylate group show μ_2 -(κ^1 - κ^1)-chelate coordination modes. And each carboxylate group connecting neighboring Cd(II) atoms and 1,3-bis(1-imidazolyl)propane ligand to form the 2D network, which is further interacted by C–H \cdots O to form a 3D supramolecular structure. Moreover, H_2dppb is completely deprotonated in 1, 2 and 4, and partly deprotonated (Hdppb^-) in 3; their asymmetric units contain two H_2dppb ligands in 1 and 3, and one H_2dppb ligand in 2 and 4. Meanwhile, the “V”-shaped ligand play important roles in the construction of bigger open spacer framework in 1, 2 and 4.

For N-donor ligands, the differences in their lengths and configurations greatly influence the final structure of the targeted CPs. Except 1 is a semi-flexible-auxiliary ligand, the N-donor ligands can be seen as rigid-auxiliary ligand in complexes 2–4. Thus the complex 1 show a 2D + 2D \rightarrow 3D two-fold interpenetrated framework, and 3D supramolecular framework in 2–4, respectively. Due to the different configurations of the N-donor ligands, complex 2 shows a higher effective free volume (44.3%) than complexes 1 (10.5%) and 4 (22.9%). Hence, complex 2 may be a good candidate for application in gas/dye absorption.

Thermal analyses

To understand the thermal stabilities of compounds 1–4, their thermal behaviors were investigated by TGA (Fig. S4†). The experiments were performed on samples consisting of numerous single crystals of 1–4 under a N_2 atmosphere with

Fig. 5 Kubelka–Munk-transformed diffuse reflectance spectra of complexes 1–4.

a heating rate of $10\text{ }^{\circ}\text{C min}^{-1}$. For complex 1, the first weight loss in the temperature range of $80\text{--}150\text{ }^{\circ}\text{C}$ is consistent with the removal of the lattice H_2O (obsd: 1.1%, calcd: 1.3%). The second weight loss corresponds to the loss of the organic ligands at *ca.* $350\text{ }^{\circ}\text{C}$. The remaining weight corresponds to the formation of CdO (obsd: 23.7%, calcd: 19.1%). For complex 2, the decomposition of the compound occurs at *ca.* $330\text{ }^{\circ}\text{C}$, and the remaining weight corresponds to the formation of CdO (obsd: 33.1%, calcd: 18.2%). For complex 3, the whole structure starts to collapse at *ca.* $350\text{ }^{\circ}\text{C}$ with a result of thermal decomposition and the remaining residue of ZnO (obsd: 30.2%, calcd: 8.2%). For complex 4, the destruction of the framework occurs at *ca.* $230\text{ }^{\circ}\text{C}$, finally leading to the formation of the stoichiometric amount of CdO as a residue (obsd: 20.2%, calcd: 19.8%).

Optical band gaps

Because of the energy band gap (E_g) of CPs is closely related to its photocatalytic ability. Thus investigate the conductivity potentials of titled compounds are necessarily. And the band gap energy of CPs can be evaluated by Kubelka–Munk transformation (F):²⁷ $F = (1 - R)/2R$, where transformed from the recorded diffuse reflectance data and R is the reflectance of an infinitely thick layer at a given wavelength.²⁸ As shown in Fig. 5, the E_g values assessed from the steep absorption edge for complexes 1–4 are 2.70, 2.74, 2.28 and 2.59 eV, respectively, which indicate that complexes 1–4 are potential semi-conductive materials.^{29,30}

Luminescence properties

The luminescence properties of complexes 1–4 together with the free H_2dtpb , *bimb*, *tib*, *4,4'*-*bibp* and *1,3-bitl* ligands, were

investigated in the solid state at ambient temperature (Table S4†). The free ligands emit strong fluorescence centered at 405 nm ($\lambda_{\text{ex}} = 275\text{ nm}$) for *H₂dtpb*, 380 nm ($\lambda_{\text{ex}} = 220\text{ nm}$) for *bimb*, 371 nm ($\lambda_{\text{ex}} = 275\text{ nm}$) for *tib*, 378 nm ($\lambda_{\text{ex}} = 270\text{ nm}$) for *4,4'*-*bibp* and 385 nm ($\lambda_{\text{ex}} = 280\text{ nm}$) for *1,3-bitl* respectively. After metallization of these ligands with Cd(II)/Zn(II) atom, the main emission peaks occur at 375 nm ($\lambda_{\text{ex}} = 275\text{ nm}$) for 1, 369 nm ($\lambda_{\text{ex}} = 270\text{ nm}$) for 2, 376 nm ($\lambda_{\text{ex}} = 265\text{ nm}$) for 3, and 383 nm ($\lambda_{\text{ex}} = 255\text{ nm}$) for 4. In comparison to the free ligands, the emission peaks of 1–4 are close to imidazol ligands, so the emission bands of these complexes can probably be attributed to the N-donor ligand fluorescence emission. Compared to the free N-donor ligand, their peaks are blue-shifted by 5 nm, 2 nm, 2 nm and 2 nm, respectively. These emissions are neither metal-to-ligand charge transfer (MLCT) nor ligand-to-metal charge transfer (LMCT) in nature, since Cd(II) and Zn(II) ions are difficult to oxidize or reduce due to their d^{10} configuration.³¹ The photoluminescent of 1–4 may originate from the intraligand $\pi^*-\pi$ or π^*-n transition since similar emissions were also observed for the ligands themselves. The emission discrepancy of these compounds is probably due to the differences of organic ligands and coordination environments of central metal ions, which have a close relationship to the photoluminescence behavior.³² As shown in Fig. 6a, with the maximum emission peaks of 1–4 are mainly centered at 375, 369, 376 and 383 nm, respectively, and bright blue, blue, blue and blue fluorescence are found by visual observation at the optimum excitation. Their chromaticity coordinates (1–4) are (0.1585, 0.0221), (0.1441, 0.0486), (0.1428, 0.0518) and (0.1492, 0.0386) (Fig. 6b).

As we know that the luminescence characteristic of PLCCs is closely related to their structures.³³ The size of the metal, the

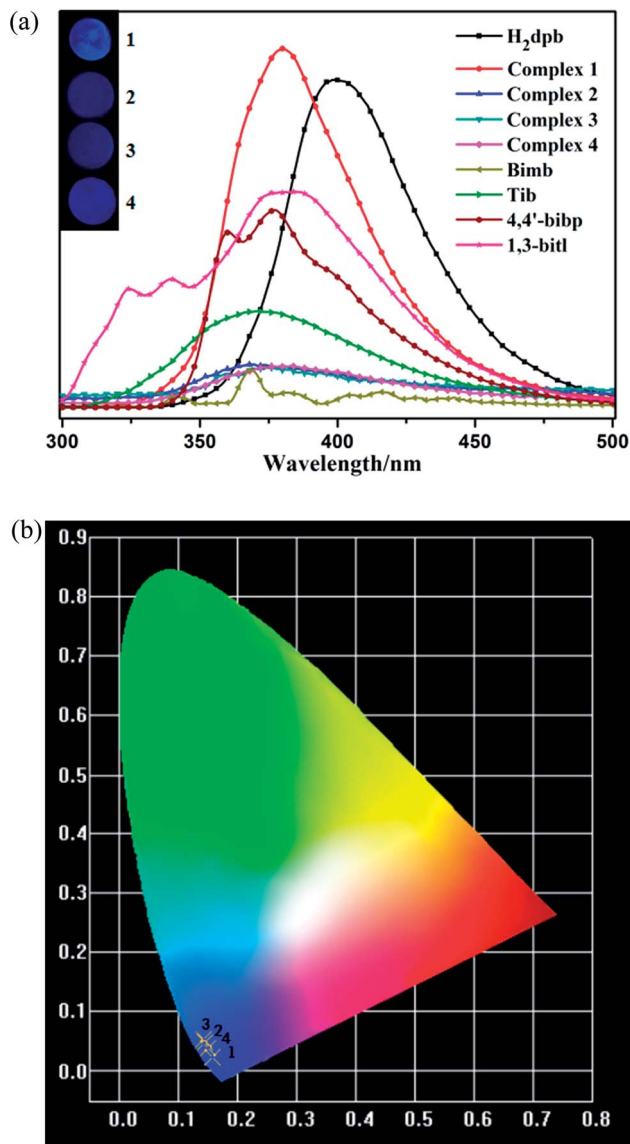

Fig. 6 (a) Photoluminescence of CPs 1–4 at room temperature in the solid state. The inset shows the relative fluorescence images. (b) CIE chromaticity diagrams of 1–4.

structure of the secondary building units (SBUs) and the orientation of the linkers all affect the emission properties of the material.³⁴ Compounds 1–4 contain the same linker (H_2dpb) in different coordination modes and geometries, allowing comparative study of their photoluminescence diversity. Here we observed that compounds 2 (blue), 3 (blue) and 4 (blue) display similar emission character, which is different from that of 1 (bright blue). The different visual fluorescence maybe attributed to the various structures of four complexes (1 (3D), 2 (2D), 3 (1D) and 4 (2D)).

Fe^{3+}/Cu^{2+} -sensing properties

Currently, the luminescent MOFs have great advantages in the ion detection and separation.³⁵ Among the metal cations, the Fe^{3+}/Cu^{2+} cations are the most necessary elements involved in

biochemical processes in humans.³⁶ Based on the strong luminescence and good water stabilities of 1–4, the sensing properties of complexes on metal cations were investigated. In order to examine their sensing abilities, the luminescence spectra of 1–4 (3 mg) dispersed in water solutions (3 mL) of 0.01 M ($mol\ L^{-1}$) $AgNO_3$ or MCl_x ($M = Na^+, K^+, Ca^{2+}, Mg^{2+}, Cd^{2+}, Mn^{2+}, Co^{2+}, Zn^{2+}, Ni^{2+}, Cu^{2+}, Fe^{3+}$) were studied. Each suspension solution was sonicated in the dark for 30 min before fluorescence testing. As can be seen in Fig. 7, complexes 2 and 3 exhibit the obvious luminescence quenching when Fe^{3+} ions were loaded, whereas other metal ions exhibit no quenching effects. Meanwhile, complex 1 also show luminescence quenching when $Ag^+, Cu^{2+}, Fe^{3+}, Ni^{2+}$ and other ions were added. Interestingly, the Cu^{2+} ions can bring pronounced complete quenching in 4, and the Fe^{3+} ions do not exhibit the obvious luminescence quenching. Those results demonstrate that compounds 2 and 3 could be highly effective and selective luminescent sensors for Fe^{3+} ions, and complex 4 could be highly effective and selective luminescent sensors for Cu^{2+} ions. It is generally accepted that the N atoms in the complexes can donate their lone-pair of electrons to the Fe^{3+}/Cu^{2+} cation, which can form electron-deficient regions and act as acceptors. When under light, the luminophore in the complex can become electron donors. The energy migrations occur in case of the electrons transferred from luminophores to acceptors (Fe^{3+}/Cu^{2+}), which leading to the fluorescence quenching.^{37,38}

For further examining the sensitivity of luminescence quenching, the concentration-dependent studies were carried out in the presence of Fe^{3+} (in 2 and 3)/ Cu^{2+} (in 4) with different concentrations. As shown in Fig. 8, the emission intensities 2–4 decreased gradually with increasing of Fe^{3+} (in 2 and 3)/ Cu^{2+} (in 4) from 0 to 5×10^{-3} M.³⁹ The Stern–Volmer equation ($I_0/I - 1 = K_{sv}C_{[M]}$) can be used to calculated the corresponding quenching coefficient, in which the values I_0 and I are the luminescent intensities of 2–4 without and with addition of Fe^{3+}/Cu^{2+} , respectively, K_{sv} is the quenching constant, and $C_{[M]}$ is the concentration of metal ions.⁴⁰ Based on the luminescent data, the K_{sv} were 1.212×10^4 for 2, 9.383×10^3 for 3 and 4.894×10^4 for 4, respectively. The K_{sv} value can be used to evaluate the metal ions selective and sensitive sensing of complexes. The higher K_{sv} of 2 demonstrates that the luminescent quenching effect for Fe^{3+} ions of 2 are more sensitive than 3. Meanwhile, the luminescent quenching effect for Cu^{2+} ions of 4 are more sensitive than 2 and 3.

The above luminescent studies indicate that 2 and 3 could selectively sense the exoteric Fe^{3+} through the luminescent quenching, and 4 could be highly effective and selective luminescent sensors for Cu^{2+} ions. The PXRD patterns of the Fe^{3+}/Cu^{2+} loaded 2–4 were nearly corresponded with the original samples (Fig. S5†). The results show that their basic frameworks are stable after loaded metal ions.

$Cr_2O_7^{2-}$ -sensing properties

Encourage by the metal ions' high selective and sensitive of 1–4, their sensing of trace anions in aqueous were investigated

Fig. 7 Emission spectra and intensities for 1 (a), 2 (b), 3 (c) and 4 (d) in solutions of different metal cations.

through the way that polymers 1–4 (3 mg) were soaked in an aqueous solution (3 mL) of 0.01 M K_2CO_3 , $K_2Cr_2O_7$, $K_2S_2O_8$, K_2SO_4 , $KSCN$, CH_3COOK , KCl , $KClO_3$, KIO_3 , KNO_3 , KOH and

KH_2PO_4 . After the polymer-anion suspensions were sonicated in the dark for 30 min, the photoluminescent spectra were investigated. As shown in Fig. 9, the four titled complexes with other

Fig. 8 Emission spectra and linear relationships for 2 (a), 3 (b) and 4 (c) in aqueous solutions of different $\text{Fe}^{3+}/\text{Cu}^{2+}$ concentrations.

anions do not exhibit the obvious luminescence quenching except $\text{Cr}_2\text{O}_7^{2-}$, which exhibited an obviously quenching effect. The absorption bands of the $\text{Cr}_2\text{O}_7^{2-}$ (two wide absorption

bands from 230 to 413 nm)⁴¹ almost cover the whole ranges of absorption bands that arise from complexes 1–4 (320–450 nm). Therefore, the luminescence quenching may be caused by the

Fig. 9 Emission spectra and intensities for 1 (a), 2 (b), 3 (c) and 4 (d) in solutions of different anions.

competition of excitation energy between the complexes and Cr₂O₇²⁻.³⁸ The PXRD results reveal that four titled compounds were stable after sensing Cr₂O₇²⁻ (Fig. S5†).

As shown in Fig. 10, the luminescence intensities of 1–4 are gradually decreased with increasing Cr₂O₇²⁻ concentrations, and the luminescence intensities are almost completely

Fig. 10 Emission spectra and linear relationships for 1 (a), 2 (b), 3 (c) and 4 (d) in aqueous solutions of different Cr₂O₇²⁻ concentrations.

quenched at the concentrations of 5×10^{-4} M. The K_{sv} values calculated by Stern-Volmer equation are 6.254×10^3 , 4.894×10^4 , 4.357×10^4 and 1.045×10^4 , respectively. Thus, the

complexes 2–4 are much more sensitive than 1 in detecting Cr₂O₇²⁻. Moreover, complexes 2–4 show high sensitivities in sensing Cr₂O₇²⁻ noxious anion compared with other reported

Fig. 11 (a) Absorption spectra of the RhB solution in the presence of complex 3. (b) Plots of concentration ratios of RhB (c/c_0) against irradiation time (min) in the presence of complexes 1–4 and without any catalyst during the decomposition reaction under UV irradiation.

Fig. 12 (a) Absorption spectra of the MB solution in the presence of complex 3. (b) Plots of concentration ratios of MB (c/c_0) against irradiation time (min) in the presence of complexes 1–4 and without any catalyst during the decomposition reaction under UV irradiation.

CPs.^{41–43} The high sensitivity indicates that complexes 2–4 may be a good candidate for the sensing of $\text{Cr}_2\text{O}_7^{2-}$ anion in industry.

Photocatalysis properties

Photocatalysts have attracted much attention due to their potential applications in purifying water by thoroughly decomposing organic compounds.⁴⁴ It is well known that rhodamine B (RhB) and methylene blue (MB) are the most common organic dyes in waste water, and some MOFs show photocatalytic activity in the degradation of organic dyes under UV irradiation by oxidation of organic materials.⁴⁵ Here, we investigated the photocatalytic ability of the title complexes (1–4) towards the degradation of RhB and MB under UV irradiation. The photocatalytic experiments were performed by the following process:⁴⁶ 20 mg of 1, 2, 3 and 4 was dispersed in 100 mL aqueous solution of RhB (6 mg L^{-1}) or MB (6 mg L^{-1}), respectively. For the adsorption–desorption equilibrium, the mixture was stirred in the dark for 30 min before turning on the Hg lamp (125 W). After centrifugation of the sample, the transparent solution was tested under UV measurement.⁴⁷

The photocatalytic activities of 1–4 in RhB solution are shown in Fig. 11a and S6.† From the Fig. 11a and S6,† we can

found that the absorbance peaks of RhB decreased obviously with different photocatalytic efficiency after the compounds were added. Moreover, the concentration ratios of RhB (c/c_0) against irradiation time (min) in the presence of the complexes 1–4 were plotted, with c_0 representing the initial concentration of RhB after magnetically stirring in the dark for 30 min (Fig. 11b). For complexes 1–4, the RhB solution has been taken out every 15 min, but the photocatalytic efficiency is different. The degradation ratios of RhB are 90.2% for 1, 82.7% for 2 and 95.1% for 4 after 135 min of UV irradiation except complex 3 (97.1% and 98.7% after 75 and 90 min), and the remarkable photocatalytic activity is $3 > 4 > 1 > 2$. Meanwhile, all the RhB degradation ratios of control experiments did not surpass 30% and nearly cease after 150 min (91.8% for 1, 85.3% for 2, 98.7% for 3 and 95.1% for 4) under UV irradiation.

As shown in Fig. 12 and S7,† the degradation ratios of MB are 93.2% for 1, 85.6% for 2 and 94.9% for 4 after 120 min of UV irradiation except complex 3 (96.5% after 75 min). The MB degradation ratios of control experiments did not surpass 30% and nearly cease after 150 min under UV irradiation. From photocatalytic degradation results, we found that the complex 3 much better than the complex 1, 2 and 4 in RhB and MB.

Fig. 13 Degradation rates of the RhB and MB solutions in the presence of complexes 1–4.

Moreover, the photocatalytic activity of the complex 1, 2, 3 and 4 is better in MB solution compared with RhB solution in 120 min (Fig. 13).

Fig. 11b and 12b show that the titled complexes have good photocatalytic activities for the photodegradation of RhB and MB under UV irradiation, and the degradation activity $3 > 4 > 1 > 2$, which corresponding with the optical band gaps (E_g values: 2.70 eV for 1, 2.74 eV for 2, 2.28 eV for 3 and 2.59 eV for 4). As we know, for complex structures, the numbers of the coordinated water molecules, the coordination environments of the central metals, the extent of the conjugation⁴⁸ and optical band gap could influence the photocatalytic activities. Therefore, it can be surmised that the low optical band gap and coordination environments of Zn(II) (four-coordination) of 3 aided in the transport of excited holes/electrons to the surface to initiate the photocatalytic decomposition reaction. Moreover, all of the titled d¹⁰ compounds (1–4) show a better photocatalytic activity compared with reported similar Cd(II)/Zn(II) CPs^{28,49} in the degradation of MB under the same condition (Table S5[†]). Thus, complex 3 may be candidates for photocatalytic activity in the degradation of some organic dyes.

When the complex is exposed under UV light, the 2p bonding orbital of the oxygen and/or nitrogen atom which in metal complex could transfer an electron from the highest occupied molecular to the lowest unoccupied molecular orbital (an empty metal orbital). Then the water molecule would captured one electron for the stable of highest occupied molecular orbital. Meanwhile, the water molecule was oxygenated into the $\cdot\text{OH}$ radical. The $\cdot\text{OH}$ active species could decompose RhB and MB effectively to complete the photocatalytic process.⁵⁰ Meanwhile, the PXRD results revealed that four Cd(II)/Zn(II) compounds were stable in degradation process, as shown in Fig. S8.[†]

Conclusions

In summary, four LCPs were synthesized based on “V”-shaped 3,5-di(4'-carboxyl-phenyl)benzene acid (H_2dpb) and four different imidazole bridging linkers (bimb, tib, 4,4'-bibp and

1,3-bitl) under hydrothermal conditions, with the final packing structures exhibiting a systematic variation of architectures from 1D chains based supramolecular to 3D interpenetrated frameworks. These results reveal that nature of the bridging N-donor linkers have significant effects on the H_2dpb coordination modes and the final packing structures. Moreover, the luminescent sensing of metal cations and anions through fluorescence quenching were investigated systematically and quantitatively. The results demonstrate that 2 and 3 display high sensitive and selective luminescent sensing towards Fe^{3+} ion, and 4 display high sensitive and selective luminescent sensing towards Cu^{2+} ion. Both 1–4 can work as high sensitive sensors to $\text{Cr}_2\text{O}_7^{2-}$ by luminescent quenching. And the photocatalytic studies indicate that complex 3 is good candidates for the photocatalytic degradation of rhodamine B (RhB) and methylene blue (MB).
