H$_3$PW$_{12}$O$_{40}$ supported on functionalized polyoxometalate organic–inorganic hybrid nanoparticles as efficient catalysts for three-component Mannich-type reactions in water†

Roushan Khoshnavazi,* Leila Bahrami, Forugh Havasi and Elham Naseri

Two new types of catalyst were synthesized by the immobilization of H$_3$PW$_{12}$O$_{40}$ (HPW$_{12}$) on the surface of organic–inorganic polyoxometalate nanoparticles of H$_6$Cu$_2$(PPDA)$_6$[SiW$_9$Cu$_3$O$_{37}$]-12H$_2$O (HybPOM) (PPDA = p-phenylenediamine) and Go/Fe$_3$O$_4$/HybPOM nanoparticles. These catalysts were characterized by thermogravimetric analysis (TGA), Fourier transform infrared (FT-IR) spectroscopy, scanning electron microscopy (SEM), energy dispersive X-ray analysis (EDX) and alternating gradient force magnetometry (AGFM). The IR spectroscopy as well as XRPD reveal that HPW$_{12}$ were immobilized on the support. The potentiometric titration with n-butylamine reveal that the catalysts can be classified as strong acids. The results show that the particles are mostly spherical in shape and have an average size in the range of 20–50 nm. The catalytic activities of the catalysts were probed through one-pot three-component Mannich-type reactions of aldehydes, amines and ketones in water at room temperature. The catalysts were re-used at least five times without any loss of their high catalytic activity.

1. Introduction

Polyoxometalates (POMs), discrete anionic metal-oxo clusters, can be linked together through cationic moieties to build materials with incredible structural diversity which exhibit a wide variety of compositions and structural versatility, as well as important optical, catalytic, and magnetic properties. POM clusters occupy a vast parameter space between the mononuclear metalate species and the bulk oxide. POMs can also self-assemble into ordered patterns at the nanometer scale, and thus have multilevel ordered structures. The great diversity in structure and composition of POMs make them attractive materials in many fields. One focus is to use them as both homogeneous and heterogeneous catalysts in oxidation and acid promoted reactions. Heteropoly acids (HPAs) such as H$_3$PW$_{12}$O$_{40}$ have been extensively studied as acid catalysts for many reactions. Despite the above advantages, use of POMs is restricted owing to the fact that they are non-porous solids with low surface area (of less than 10 m$^2$ g$^{-1}$). Because of their ionic nature they dissolve well in polar solvents such as water, alcohols, ketones, acetonitrile and dimethylsulfoxide which make them difficult to separate from the reaction products and their inevitable loss during recycling. Hence, efforts have also been made to study the support of HPAs on inert or weak acidic high surface area materials such as, silica, zeolite, and alumina. The application of supported HPAs increases the specific surface area of the catalysts and modifies their catalytic properties. Thus, immobilization of HPAs on supports show a greater number of surface acid sites than their bulk components. The use of nanoparticles (NPs) offers many advantages for supporting homogeneous catalysts due to their unique size and physical properties. NPs could have a higher catalyst loading capacity and a higher dispersion than many conventional support matrices. Recently, supported HPAs have been developed for a wide range of organic reactions in fundamental research.

Easier recovery and recycling after carrying out reaction through simple separation processes are the advantages that supported HPAs have compared to homogeneous examples. In addition, heteropoly acids are more active catalysts for various reactions in solution than conventional inorganic and organic acids and they have many environmental benefits. They were tested as catalysts for several reactions with the final objective of industrial use, as alcohol dehydration, alklylation or esterification reactions. Among heteropoly acids, 12-tungstophosphoric acids are the most widely used catalysts owing to their high acid strength and thermal stability, and relatively low reducibility. Recently, the supported heteropoly acids as heterogeneous catalysts have attracted much attention. H$_3$PW$_{12}$O$_{40}$ have been immobilized on Fe$_3$O$_4$ functionalized nanoparticles and successfully

applied as active species in organic reaction catalysis.\(^{32,33}\) In this study, organic–inorganic nanohybride of HybPOM was used as a new kind of high surface area material for supporting homogeneous H\(_2\)PW\(_{12}\)O\(_{40}\). The functionalized organic–inorganic polyoxometalates of HybPOM was synthesized by a simple and high yield reaction.\(^{34}\) Ultimately, mixing a suspension of HybPOM with an ethanolic solution of HPW\(_{12}\) leads to the formation of HybPOM/HPW\(_{12}\) NPs which involves the reaction of H\(_2\)PW\(_{12}\)O\(_{40}\) with surface amine groups of HybPOM. Protonation of amine groups gives positively charged cations which bound electrostatically to the heteropolyanions.

Despite the high surface areas of HybPOM/HPW\(_{12}\), filtration or centrifugation is needed and the separation process is still a difficult and time consuming process. Magnetic nanoparticles are excellent supports for various catalysts\(^{35,36}\) and can easily be separated and recycled from the products by an external magnet. Surface functionalized Go/Fe\(_3\)O\(_4\) nanoparticles are a kind of novel functional material which has been widely used in biotechnology and catalysis. The Go/Fe\(_3\)O\(_4\)/HybPOM magnetic nanoparticle was synthesized simply by addition of HybPOM to the ethanol disperse solution of Go/Fe\(_3\)O\(_4\) nanoparticle. The GO because of its exceptionally high surface area (2630 m\(^2\) g\(^{-1}\)) and abundant oxygenate groups such as epoxy, hydroxyl, and carboxyl groups on their surface, is as an ideal support for immobilizing and improving POMs catalytic activity. The Go/Fe\(_3\)O\(_4\)/HybPOM magnetic nanoparticle was synthesized by a simple and high yield reaction.\(^{37}\) The mixture was stirred under reflux condition for 24 h. The obtained nanohybride were magnetically collected from the solution and can be easily manipulated by external magnetic field.

In this paper, we synthesized HybPOM/HPW\(_{12}\) and Go/Fe\(_3\)O\(_4\)/HybPOM/HPW\(_{12}\) nanoparticles by immobilization of Keggin type heteropoly acid H\(_2\)PW\(_{12}\)O\(_{40}\)·xH\(_2\)O on organic–inorganic nano hybrid of H\(_3\)Cu\(_2\)PDA\(_6\)[SiW\(_9\)Cu\(_3\)O\(_{37}\)·12H\(_2\)O (HybPOM) and nanocomposite of Go/Fe\(_3\)O\(_4\)/HybPOM nanoparticles, respectively and assessed their catalytic activity in Mannich-type reactions in water. Indeed, the venerable Mannich reactions and its variants represent one of the more powerful constructs for alkaloid synthesis.\(^{38}\) To the best of our knowledge, this is the first report containing immobilization of a heteropolyacid on organic–inorganic nano hybrid. Synthesis, characterization and catalytic application of new nano catalysts have been investigated.
collected, washed three times with ethanol (3 x 5 mL), and dried at 50 °C under reduced pressure.

**Titration of the catalysts acidity**

The acidity of HybPOM/HPW₁₂ and Go/Fe₃O₄/HybPOM/HPW₁₂ was probed by potentiometric titration.⁴⁰ HybPOM/HPW₁₂ or Go/Fe₃O₄/HybPOM/HPW₁₂ (0.05 g) was suspended in acetonitrile, and stirred for 3 h. Then, the suspension was titrated with 0.05 M n-butylamine in acetonitrile at 0.05 mL min⁻¹. The electrode potential variation was measured with a WTW digital nanolab model using a double-junction electrode.

**General procedure for the synthesis of β-amino ketones catalyzed by HybPOM/HPW₁₂**

Typically, the catalyst (0.005 g) was added to a mixture of aldehyde (1 mmol), amine (1 mmol), cyclohexanone (2 mmol) and H₂O (1 mL). The reaction mixture was vigorously stirred at room temperature for an appropriate time. The progress of the reaction was monitored by TLC. After completion of the reaction, the catalyst was separated by centrifugation, washed with ethanol and water, vacuum dried and stored for subsequent runs. The reaction mixture was extracted with H₂O and EtOAc. The organic layer was dried over MgSO₄ and then evaporated under reduced pressure. The crude products were purified either by crystallization from ethanol, giving of β-amino ketones in good yield.

**Characterization of organic products**

2-(Phenyl(phenylamino)methyl)cyclohexanone (Table 2, entry 1). White solid, mp 128–129 °C;¹¹¹ FT-IR (KBr, cm⁻¹) 1440–1594 (C=O, aromatic), 1701 (C≡O, carbonyl), 3349 (NH, second amine), 2925, 2860 (C–H, aliphatic), 3015 (C–H, aromatic). ¹H NMR (250 MHz, CDCl₃) δ (ppm): 7.80 (s, 1H), 7.45–7.26 (m, 7H), 6.68–6.64 (m, 2H), 4.80 (d, 0.38H, J = 2.25 Hz), 4.63–4.60 (m, 0.36H, J = 6.73 Hz), 2.94–2.84 (m, 2H), 2.54–2.34 (m, 2H), 1.91–1.77 (m, 4H), 1.25 (s, 1H). (syn/anti: 50/50). EI-MS (70 eV): m/z (%) = 279 [M⁺, 11], 182 [M⁺–C₆H₅O, 48].

2-((2-Chlorophenyl)(phenylamino)methyl)cyclohexanone (Table 2, entry 2). White solid, mp 137–139 °C;¹¹¹ FT-IR (KBr, cm⁻¹) 1434–1600 (C≡C, aromatic), 1704 (C≡O, carbonyl), 3380 (NH, second amine), 2933, 2857 (C–H, aliphatic), 3045 (C–H, aromatic); ¹H NMR (250 MHz, CDCl₃) δ (ppm): 7.91 (s, 1H), 7.51–7.40 (m, 3H), 7.33–7.26 (m, 3H), 6.65–6.62 (m, 1H), 6.51 (d, 1H, J = 8 Hz), 5.33 (d, 0.30H, J = 3.25 Hz), 4.89 (d, 0.41H, J = 4.5 Hz), 2.77–2.54 (m, 7H), 1.96–1.92 (m, 2H). (syn/anti: 42/58). EI-MS (70 eV): m/z (%) = 315 [M⁺ + 2, 3], 313 [M⁺, 9], 216 (M⁺–C₆H₅O, 100).

2-((4-Bromophenyl)(phenylamino)methyl)cyclohexanone (Table 2, entry 3). White solid, mp 109–110 °C;¹¹¹ FT-IR (KBr, cm⁻¹) 1484–1610 (C≡C, aromatic), 1709 (C≡O, carbonyl),

3380 (NH, second amine), 2927, 2856 (C–H, aliphatic), 3029 (C–H, aromatic), 418 NMR (250 MHz, CDCl₃) δ (ppm): 7.49–7.41 (m, 2H), 7.34–7.39 (m, 2H), 7.26–7.23 (m, 2H), 7.23–7.07 (m, 2H), 6.69–6.64 (m, 1H), 6.51 (d, 1H, J = 6 Hz), 4.72 (d, 0.41H, J = 4 Hz), 4.58 (d, 0.54H, J = 6.25 Hz), 2.78–2.76 (m, 1H), 2.53–2.38 (m, 1H), 2.36–2.31 (m, 1H), 1.94–1.71 (m, 6H). (sym/anti: 43/57); EI-MS (70 eV): m/z (%) = 359 [M⁺ + 2], 357 [M⁺, 7], 260 [M⁺–C₆H₄O, 100].

2-(4-Chlorophenylamino)(phenyl)methyl)cyclohexanone (Table 2, entry 5). White solid, mp 137–138 °C; FT-IR (KBr, cm⁻¹) 1490–1592 (C=C, aromatic), 1703 (C=O, carbonyl), 3369 (NH, second amine), 2940, 2850 (C–H, aliphatic), 3052 (C–H, aromatic); EI-MS (70 eV): m/z (%) = 315 [(M⁺ + 2), 3], 313 (M⁺, 9), 216 (M⁺–C₆H₄O, 85).

3. Results and discussion

Characterization of nanomaterials

The results of IR spectrum showed that all amine groups on the surface HybPOM were not linked to the GO–Fe₃O₄ magnetic nanoparticle. Therefore, H₃PW₁₂O₄₀ might interact with the reflected free amine groups on the surface GO–Fe₃O₄ for the formation of GO/Fe₃O₄/HybPOM/HPW₁₂ nanoparticles. The catalytic ability of the prepared HybPOM/HPW₁₂ and GO/Fe₃O₄/HybPOM/HPW₁₂ hybrid composite was evaluated in synthesis of various β-amino ketones via Mannich reactions in aqueous media. The schematic pathway for preparation GO/Fe₃O₄/HybPOM/HPW₁₂ hybrid composite is presented in Scheme 1.

IR spectra of HybPOM, HybPOM/HPW₁₂ and HPW₁₂ samples are shown in Fig. 1. The PW₁₂O₄₀⁻ Keggin ion structure is well known and shows typical bands for absorptions at 1081 (P=O), 985 (W=O), 897 and 803 (W–O–W) cm⁻¹. As a result, the new peaks are observed at 1079 and 962 cm⁻¹ in IR spectra of HybPOM/HPW₁₂ indicating that HPW₁₂ was anchored onto HybPOM successfully. IR spectra of GO/Fe₃O₄/HybPOM, GO/Fe₃O₄/HybPOM/HPW₁₂ and HPW₁₂ samples are shown in Fig. 2.

In Fig. 2, peaks at 573–630 cm⁻¹ in the GO/Fe₃O₄/HybPOM/HPW₁₂ composite are attributed to Fe–O stretching vibration and the peak at 1080 cm⁻¹ is attributed to the asymmetric stretching vibration P–O.

The XRD diffraction patterns of GO/Fe₃O₄/HybPOM (a) and GO/Fe₃O₄/HybPOM/HPW₁₂ (b) and GO/Fe₃O₄/HybPOM/HPW₁₂ (c) are shown in Fig. 3. X-ray diffractions pattern of HybPOM, as a typical amorphous state material is observed in the X-ray spectra of HybPOM/HPW₁₂ and GO/Fe₃O₄/HybPOM/HPW₁₂. In Fig. 3, peaks corresponding to the Fe₃O₄ are observed at 2θ = 30.52°, 35.85°, 43.58°, 53.96°, 57.43°, 63.16° and 74.65° which match well with the standard Fe₃O₄ sample (JCPDS file no. 19-0629).⁴⁰

The peaks corresponding to HPW₁₂ at 2θ = 30.52°, 35.85°, 43.58°, 53.96°, are observed in X-ray powder diffractions of HybPOM/HPW₁₂ and GO/Fe₃O₄/HybPOM/HPW₁₂ which match well with the X-ray powder diffraction pattern of H₃PW₁₂O₄₀⁻·6H₂O.⁴⁰ The X-ray powder diffractions thus confirm that the Keggin structure of the HPW₁₂ compound was preserved with its immobilization on the supports.

Numerous methods have been employed to describe the acidity of POMs in the solid state both qualitatively and quantitatively. Titration with Hammett indicators, temperature programmed desorption of adsorbed molecules such as ammonia or pyridine, adsorption microcalorimetry, NMR spectroscopy and catalytic probe reactions are the most common methods for characterizing solid acids. The nature of the support apparently affects the acidity of the supported HPAs by means of potentiometric titration with n-butylamine allows the estimation of the number of acid sites and their distribution.

The titration curves obtained for HybPOM and HybPOM/HPW₁₂ are illustrated in Fig. 4A and those of Go/Fe₃O₄/HybPOM and Go/Fe₃O₄/HybPOM/HPW₁₂ are shown in Fig. 4B. It is believed that the initial electrode potential (Eᵢ) indicates the maximum strength of the acid sites and the value from which the plateau is reached (meq. n-butylamine/total amount of meq. H⁺) indicates the total number of acid sites that are present in the titrated solid. On the other hand, the acid strength of these sites may be classified according to the following scale: Eᵢ > 100 mV (very strong sites), 0 < Eᵢ < 100 mV (strong sites), −100 < Eᵢ < 0 (weak sites) and Eᵢ < −100 mV (very weak sites). The HybPOM (Fig. 4A(a)) and Go/Fe₃O₄/HybPOM (Fig. 4B(a)) showed very weak and weak acid sites (Eᵢ = −165.9 and −73.8 mV), respectively. Difference in the acid strength of HybPOM and Go/Fe₃O₄/HybPOM is attributed to the total number of free NH₂ groups on them. For Go/Fe₃O₄/HybPOM, some of the NH₂ groups are involved in the bonding with Go/Fe₃O₄ nanoparticles.

As expected, the strength of the acid sites of the HPW₁₂ decreases with its addition to the HybPOM and Go/Fe₃O₄/
HybPOM surfaces. This effect depends on the extent of the interaction of HPW₁₂ with the support. According to potentiometric titration curves, HPW₁₂ presented very strong acidic sites ($E_i = 572.2$ mV).¹⁴ Potentiometric titration results of HybPOM/HPW₁₂ (Fig. 4A(b)) and Go/Fe₃O₄/HybPOM/HPW₁₂ (Fig. 4B(b)) samples showed the lower $E_i$ value of 74.1 and 80 mV, respectively compared to the HPW₁₂ which might be a result of a strong interaction with the HybPOM and Go/Fe₃O₄/HybPOM support. Here, differences in the acid strength of HybPOM/HPW₁₂ and Go/Fe₃O₄/HybPOM/HPW₁₂ samples are attributed to the total number of free NH₂ groups on HybPOM and Go/Fe₃O₄/HybPOM support.

The magnetization of GO–Fe₃O₄, Go/Fe₃O₄/HybPOM and Go/Fe₃O₄/HybPOM/HPW₁₂ samples was measured at room temperature as shown in Fig. 5. The specific saturation magnetization of GO–Fe₃O₄ is 29.2 emu g⁻¹ value is smaller than the reported value of bulk Fe₃O₄ of 92 emu g⁻¹.⁴⁵ The specific saturation magnetization, of Go/Fe₃O₄/HybPOM and Go/Fe₃O₄/HybPOM/HPW₁₂ are 22.47 and 16.64 emu g⁻¹, respectively. A decrease in saturation magnetization observed for Go/Fe₃O₄/HybPOM and Go/Fe₃O₄/HybPOM/HPW₁₂ could be attributed to the increased mass and the loading of the HybPOM and HPW₁₂. Even with this reduction in the saturation magnetization, complete magnetic separation of Go/Fe₃O₄/HybPOM and Go/Fe₃O₄/HybPOM/HPW₁₂ was achieved in <10 s by placing a magnet near the vessels containing the aqueous dispersion of the nanoparticles.

Fig. 6 shows the SEM images of HybPOM (a), HybPOM/HPW₁₂ (b), Go/Fe₃O₄/HybPOM (c) and Go/Fe₃O₄/HybPOM/HPW₁₂ (d). The images indicate the nano compounds after immobilization of HPW₁₂ preserved the relatively uniform spherical nanometer particles of diameter in the range 20–50 nm. EDX analysis (Fig. 7) of HybPOM/HPW₁₂ (a) and Go/Fe₃O₄/HybPOM/HPW₁₂ (b) nanoparticles show peaks of W, O, Si, C, N, Cu, P and C, O, Fe, W, Si, N, Cu, P respectively, the obtained element percentages of which are fairly consistent with the TGA results.

TGA was conducted in the range of 30–800 °C and the TGA plot of Go/Fe₃O₄/HybPOM (a) and Go/Fe₃O₄/HybPOM/HPW₁₂ (b).
are depicted in Fig. 7. Although, the TGA profile of Go/Fe₃O₄/HybPOM/HPW₁₂ shows continuous weight loss in the range of 30–800 °C, only three weight loss steps can be observed. The first weight loss (ca. 2.5%) that occurred below 150 °C is related to the loss of physisorbed water at the hybrid material surface. A main weight loss (14.00%) in the range of 150–425 °C is assigned to the decomposition of the Go/Fe₃O₄/HybPOM nanocomposite support. The third weight loss (ca. 8.28%) in the range of 425–600 °C is due to partial decomposition of H₃PW₁₂O₄₀ (ref. 29) and residual Go/Fe₃O₄/HybPOM nanocomposite. The TGA analysis indicates that the prepared Go/Fe₃O₄/HybPOM/HPW₁₂ is thermally stable at temperatures lower than 150 °C. The total weight loss of Go/Fe₃O₄/HybPOM/HPW₁₂ (27.7 wt%) was less than that of Go/Fe₃O₄/HybPOM (32.4 wt%) because of additional residual from partial decomposition of H₃PW₁₂O₄₀.

Recycling experiments for catalysts were performed by the Mannich condensation of benzaldehyde, aniline and cyclohexanone in water. The model reaction was carried out by using 0.01 g of the catalysts. Fig. 8 shows the yield of five consecutive cycles for the preparation of 2-(phenyl(phenylamino)methyl)cyclohexanone in the presence of HybPOM/HPW₁₂ (a) and Go/Fe₃O₄/HybPOM/HPW₁₂ (b). When the reaction was completed, catalysts are separated and water was removed from the mixture to leave a residue. Then, the product was dissolved in ethyl acetate and the catalyst easily separated from the product by centrifuge or with the aid of an external magnet, followed by decantation of the product solution. The remaining catalysts were washed with ethanol and water to remove the residual product, dried under vacuum and re-used in a subsequent reaction. The catalysts have been observed to be re-usable for at least five times without loss of activity.

a detectable catalytic leaching or an appreciable change in activity. High catalytic activity and significantly low leaching of catalysts (during catalytic reactions) were observed by titration of acid content. The potentiometric titration curve of the re-used catalysts showed that all of their acidic sites were preserved during five cycles and HPW_{12} leaching was negligible (Fig. 4A(c) and B(c)). The FT-IR spectra showed no significant structural changes for catalysts after five consecutive runs (Fig. 9).

**Catalytic studies**

The Mannich-type reactions are very important carbon–carbon bond-forming reactions in organic synthesis and one of the most widely utilized chemical transformations for constructing β-amino ketones and other β-amino carbonyl compounds.\(^{46,47}\) Recently, direct Mannich reactions of aldehydes, ketones and aryl amines have been realized \textit{via} Lewis acids, lanthanides, transition metal salt catalysis and organocatalytic approaches.\(^{47-50}\) Most of these methods suffer from severe drawbacks including the use of a large amount of catalysts, expensive reagents or catalysts, sometimes long reaction times and low yield. The use of environmentally benign solvents in organic reactions have attracted much attention and another key research area of green chemistry, with great advances being seen in aqueous catalysis. Use of water in addition to its being

\(^{a}\) All the products were identified and characterized by comparison of their physical and spectral data with those of authentic samples. \(^{b}\) Isolated yield.
an environmentally benign solvent show unique selectivity and reactivity. In this study, the catalytic activity of HybPOM/HPW$_{12}$ and Go/Fe$_3$O$_4$/HybPOM/HPW$_{12}$ nanoparticles were investigated through one-pot three-component Mannich-type reactions of aldehydes, amines and cyclohexanone in water as a novel, efficient and heterogeneous catalyst under mild conditions. First, in order to optimize the Mannich-type reaction conditions, the reaction was performed with benzaldehyde, aniline and cyclohexanone as a model reaction (Table 1). As shown in Table 1, 0.005 and 0.007 g of catalysts were found to be ideal for the Mannich-type reactions and the best results were obtained using 1 mL water as solvent. The control experiments carried out using homogenous H$_3$PW$_{12}$O$_{40}$·xH$_2$O and Go/Fe$_3$O$_4$/HybPOM showed that the mixed Mannich product and imine were formed. When using H$_3$PW$_{12}$O$_{40}$·xH$_2$O as a homogenous catalyst, approximately 80% and 15% of the Mannich product and imine were formed, respectively. However, when Go/Fe$_3$O$_4$/HybPOM was used as a catalyst, approximately 65% of the Mannich product was formed. The reaction was extended to a series of aldehydes, cyclohexanone and amines to explore the generality of this catalytic system (Table 2).

The formed anti and syn isomers in the Mannich-type reactions were identified by the coupling constants (J) of the vicinal protons adjacent to C=O and NH in their $^1$H NMR spectra. The coupling constant (J) for the anti-isomer is higher than that of the syn. The anti/syn ratio was determined by $^1$H NMR judged by the intensity of the H$_1$ (Scheme 2).
A possible mechanism of the Mannich-type reaction in the presence of HybPOM/HPW₁₂ and Go/Fe₃O₄/HybPOM/HPW₁₂ as Bronsted acid catalysts is proposed (Scheme 3). The reaction proceeded typically through the imine formation of the aldehyde and amine, protonation of the imine, and the attack of the enol derived from the ketone to the protonated imine, leading to the formation of Mannich products.

As shown in Scheme 4, an intermediate arn are formed via hydrogen bonds formation among Go/Fe₃O₄/HybPOM/HPW₁₂, the imine and the enol form of cyclohexanone. In the intermediate the aryl groups of aldime and the methylene groups of cyclohexanone would be anti to each other and there would be less steric repulsion. Therefore, the most stable transition state would produce the anti isomer. ²²

4. Conclusion
The new nanoparticle catalysts were synthesized by the immobilization of H₂PW₁₂O₄₀ on the surface of H₂Cu₃[PPDA]₄[SiW₁₂–

Cu₃O₇]–12H₂O (HybPOM) (PPDA = p-phenylenediamine) organic-inorganic hybrid polyoxometalates and Go/Fe₃O₄/HybPOM nanoparticle composite. The IR spectroscopy as well as X-ray powder diffraction confirmed immobilization of H₂PW₁₂O₄₀ on the supports. Potentiometric titration results show that the new nanocatalysts possessing strong and sufficient acidic sites is responsible for excellent conversion values of products. The nanocatalysts catalyzed one-pot three-component Mannich-type reactions of aldehydes, amines and ketones in water at room temperature and the catalysts were re-used at least five times without any loss of their high catalytic activity.
